TEMPERATURE. THESIS ADVISOR : THEERANUN SIRITANON, Ph.D.
74 PP.

THERMOELECTRICS/ELECTRICAL PROPERTIES/OXIDES/
CITRATE SOL-GEL METHOD

A strategy to improve the thermoelectric properties of LaCoO₃ by the double substitution of Sr and Mg in La_{1-x}Sr_xCo_{1-x}Mg_xO₃ (x = 0, 0.025, 0.05, 0.1) is presented. Effects of individual Sr or Mg substitution were also investigated separately in the series of La_{1-x}Sr_xCoO₃ and LaCo_{1-x}Mg_xO₃ (x = 0, 0.02, 0.05, 0.1, 0.2). All samples were successfully synthesized by the citrate sol-gel method. Replacing La by a small amount of Sr increases electronic conductivity but decreases the Seebeck coefficient; the decrease in the Seebeck coefficient is reduced when Mg is simultaneously substituted for Co. The employment of both Sr and Mg substitutions benefits the enhancement in thermoelectric efficiency since both electrical conductivity and Seebeck coefficient are enhanced while thermal conductivity is suppressed. With this strategy, the sample with a small amount of double substitution, La_{0.975}Sr_{0.025}Co_{0.975}Mg_{0.025}O₃, exhibits a ZT of 0.047 at room temperature.

ACKNOWLEDGEMENTS

I am so glad that all parts of this thesis have been fulfilled. Everything I have studied within this thesis has been greatly supported by my advisor, Dr. Theeranun Siritanon. She is a wonderful advisor as she is intelligent, reasonable, positive, and kind. She is an expert in the field of solid state chemistry, materials chemistry, as well as general chemistry. The way she guided me to approach these kinds of knowledge is also very interesting. Moreover, I am so grateful for her patience to advise and encourage me throughout the project. Dr. Theeranun thought reasonably and positively in every conversation we have had. This indirectly taught me to be a reasonable person who thinks positively. In addition, her kindness was the most important factor in assisting me to pass through every problem. Furthermore, she is a real teacher who opens the door of opportunity for a student when she can. I really appreciate everything she has given me. For the above reasons, it is a great pleasure being one of her students.

I would like to acknowledge the committee including Assoc. Prof. Dr. Jatuporn Wittayakun, Asst. Prof. Dr. Sanchai Prayoonpokarach, and Asst. Prof. Dr. Rapee Gosalawit-Utke. Their comments and suggestions were very useful for my thesis.

I also would like to thank Prof. Zenji Hiroi for giving me the opportunity to work in his laboratory. Thermoelectric properties measurement in this work was supported by the Institute for Solid State Physics (ISSP), The University of Tokyo. I am grateful to Dr. Yoshihiko Okamoto for his assistance in the measurements. I am honored to have had the chance to interact and learn with Prof. Zenji Hiroi and his

research group members. I also enjoyed the great opportunity of taking an educational tour at the Institute for Chemical Research and the Solid State Physics and Chemistry Laboratory, Kyoto University. Through his kindness and opened mind, I gained a great number of research and life experiences.

I am thankful to Prof. Mas Subramanian for providing his laboratory at the Department of Chemistry, Oregon State University, USA, where I learned the experimental techniques necessary to the field of Solid State Chemistry. It has been a special experience to discuss and study with him and his research group members. I would like to thank Dr. Jun Li for her valuable discussions and assistance in my experiments.

All experiments in this work could not have been done without the help and support from the people of Suranaree University of Technology: the research group member (Nararat Yong), colleagues in the School of Chemistry, colleagues in the School of Physics, and office staff in the Center for Scientific and Technological Equipment. Also, many thanks for the Center for Scientific and Technological Equipment (CSTE) and Advanced Materials Physics Laboratory (AMP) for providing facilities for my research.

Importantly, I would like to acknowledge the Thai Government for their support through the Development and Promotion of Science and Technology Talent Project (DPST) for financial supports.

Last but not least, I would like to express my deepest appreciation to my family: my father, mother, and sisters for their endless love, encouragement and support.

CHAPTER I

INTRODUCTION

1.1 Introduction

Concerning energy crisis and environmental problems, the fossil fuel consumption has unfortunately increased together with the release of toxic gases such as greenhouse gases. Moreover, the industrial system can utilize only less than 50% of fuels, while the remaining is exhausted to air as a waste heat (Ohta *et al.*, 2008). Hence, it is beneficial to increase the efficiency of the energy consumption. Among the alternative energy technologies, thermoelectric energy conversion is promising due to its ability to recycle wasted heat into electricity. Its properties allow applications on both electrical power generation and various electronic cooling devices (Elsheikh *et al.*, 2014).

The performance of thermoelectric materials is defined by the figure of merit, ZT ; $ZT = (S^2\sigma)T/\kappa$, when S , σ , and κ are Seebeck coefficient, electrical conductivity, and thermal conductivity, respectively. In general, a value of $ZT \geq 1$ is required for practical uses. The materials that show the best thermoelectric properties are alloys such as Bi_2Te_3 , PbTe , and $\text{Si}_{1-x}\text{Ge}_x$ (Mahan, 1998; Sales *et al.*, 1996; Yamashita *et al.*, 2003). However, their uses are limited at low temperature as they have low stability and high toxicity. In contrast, oxides are more environmental friendly and have excellent thermal and chemical stability. As they are chemically stable at high temperature in air, thermoelectric oxides are expected to be used in much wider

(Cheng *et al.*, 2006)

Oxides have advantage over classical heavy-element based compounds because they have higher thermal stability and ability to resist the oxidation reaction which can result in the release toxic substances (He *et al.*, 2011). Cobalt oxides are interesting in this field as they were reported to have good thermoelectric properties, for example, NaCo_2O_4 has large Seebeck coefficient of $100 \mu\text{VK}^{-1}$ at 300 K (Terasaki *et al.*, 1997), $\text{Ca}_2\text{Co}_2\text{O}_5$ has ZT of about 1.2-2.7 at ≥ 873 K (Funahashi *et al.*, 2000), and $\text{Bi}_2\text{Sr}_2\text{Co}_2\text{O}_y$ has $\text{ZT} \geq 1.1$ at 973 K (Funahashi and Shikano, 2002). Nevertheless, their layered structures lead to anisotropic properties that might cause difficulties in fabrication processes (Koumoto *et al.*, 2006). As a consequence, a perovskite-type structure of metal oxides such as LaCoO_3 (Señarís-Rodríguez and Goodenough, 1995), SrTiO_3 (Ohta *et al.*, 2005), and $\text{Ca}_{1-x}\text{M}_x\text{MnO}_3$ (when $\text{M} = \text{Tb}, \text{Ho}, \text{Y}$) (Kobayashi *et al.*, 1991) may be the potential candidate for thermoelectric applications.

LaCoO_3 -based oxides have received interest as thermoelectric materials. The important finding is the discovery of its high Seebeck coefficient of about $600 \mu\text{VK}^{-1}$ at room temperature (Señarís-Rodríguez and Goodenough, 1995). This value is higher comparing to other well-known thermoelectric cobalt oxide-based materials; for example, Na_xCoO_2 , $\text{Ca}_2\text{Co}_2\text{O}_5$, and $\text{Bi}_2\text{Sr}_2\text{Co}_2\text{O}_y$ have room-temperature Seebeck coefficient of about $100 \mu\text{VK}^{-1}$, $125 \mu\text{VK}^{-1}$, and $160 \mu\text{VK}^{-1}$, respectively. At 300 K, these cobalt oxides show figure of merit ZT of 0.6 (Terasaki *et al.*, 1997), 0.026 (Funahashi *et al.*, 2000), and about 0.023 (Funahashi and Shikano, 2002), respectively. Vulchev *et al.* (2012) also reported high Seebeck coefficient of LaCoO_3 of about $600 \mu\text{VK}^{-1}$; nevertheless, its ZT value was very low, approximately 0.015 at 300 K.

Furthermore, LaCoO_3 prepared by Iwasaki *et al.* (2008) showed similar Seebeck coefficient value of about $500 \mu\text{VK}^{-1}$ with very low ZT of 0.003 at room temperature. Despite the high Seebeck coefficient, ZT of LaCoO_3 is very low because of the low electrical conductivity (Weidenkaff *et al.*, 2008). Therefore, electrical conductivity as well as thermal conductivity has to be optimized to improve the ZT.

Doping some cations at La or Co site to create various LaCoO_3 -based oxides is a common strategy used for such improvement. Sr substitution for La is widely investigated since it was found that $\text{La}_{0.95}\text{Sr}_{0.05}\text{CoO}_3$ shows the outstanding ZT of 0.18 at 300 K (Androulakis *et al.*, 2004). Sr substitution normally increases electrical conductivity; however, it always decreases Seebeck coefficient (Mandal *et al.*, 2005; Zhou *et al.*, 2006; Zhou *et al.*, 2008a; Zhou *et al.*, 2008b; Iwasaki *et al.*, 2008). Moreover, substitution with some cations such as Ba (Hejtmánek *et al.*, 2004; Mandal *et al.*, 2004), Ca (Weidenkaff *et al.*, 2008), and Ni (Li and Li, 2011; Robert *et al.*, 2008; Kozuka *et al.*, 2012; Vulchev *et al.*, 2012; Robert *et al.*, 2006; Robert *et al.*, 2007) shows similar effects. On the other hand, some cations such as Mg (Ramadass *et al.*, 1979; Hejtmánek *et al.*, 2008; Jiráček *et al.*, 2008), and Fe (Rao *et al.*, 1975; Vulchev *et al.*, 2012) show interesting effect as their substitutions maintains the high Seebeck coefficient while the electrical conductivity is enhanced in the case of Mg and slightly decreased in the case of Fe. Considering the denominator of ZT, thermal conductivity is the only one divisor. This factor can be suppressed by some strategies including substitutions with cations such as Rh (Li *et al.*, 2010), Na, and Pb (He *et al.*, 2006).

Yet the single substitution cannot improve all parameters at the same time because they are interrelated. One of the strategies to enhance thermoelectric

properties has recently been conducted by double substitution. In 2003, Suzuki *et al.* (2003) prepared Sr and Mn double-substituted LaCoO_3 . $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{1-x}\text{Mn}_x\text{O}_3$ ($x = 0, 0.05, 0.10$) presents coexistent consequences of each dopant resulting in developed ZT although Sr and Mn work together to improve only two of three parameters. Moreover, Rodríguez *et al.* (2008) prepared $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{1-x}\text{Mn}_x\text{O}_3$ ($x = 0, 0.02, 0.03, 0.05$) and found that $\text{La}_{0.8}\text{Sr}_{0.2}\text{Co}_{0.95}\text{Mn}_{0.05}\text{O}_3$ has ZT of 0.12. Besides, Ni and Fe double substitution was investigated by Vulchev *et al.* (2012). With $\text{LaCo}_{1-x}(\text{Ni}_{0.5}\text{Fe}_{0.5})_x\text{O}_3$ formula, Ni plays an important role to heighten the electrical conductivity while Fe keeps Seebeck coefficient at high value. Furthermore, 20-50% double-substituted LaCoO_3 effectively suppresses thermal conductivity comparing to its parent compound. This work illustrates the success of simultaneous effect from each cation on amelioration for all parameters of thermoelectric properties. Therefore, numerous series of co-doping is interesting.

Herein, this study focuses on improving the thermoelectric performance of LaCoO_3 -based oxides by double substitution of La and Co with Sr and Mg. The synergic effect of the two doping cations is expected to improve the material properties favorably. At the same time, the sol-gel method is employed for all sample preparations in order to control the microstructure of materials. This sample preparation method is expected to result in smaller particles which should lower thermal conductivity. TG/DTA and FT-IR were utilized to obtain the optimal condition of syntheses. Structural identification was mainly investigated by X-Ray diffraction. Refinement using Le Bail method provided structural details of lattice parameters. In addition, the influence of both single and double substitutions of Co and/or La as well as compositions on thermoelectric properties was evaluated in the

term of the figure of merit ZT at room temperature. A Quantum Design Physical Properties Measurement System (PPMS) was employed to obtain ZT by the simultaneous measurement of electrical resistivity (ρ), Seebeck coefficient (S), and thermal conductivity (κ).

CHAPTER II

LITERATURE REVIEW

2.1 Thermoelectric materials

Thermoelectric materials exhibit the phenomenon of heat and electricity conversion. The phenomenon is based on two important effects, Seebeck (Seebeck, 1823) and Peltier effects (Peltier, 1834). The Seebeck effect, which is used in a power generation mode, is a development of voltage across the junction of two different materials held at different temperature (Figure 2.1a). On the other hand, the Peltier effect used in refrigeration mode involves a heat liberation or absorption when electrical current is applied to such junction (Figure 2.1b).

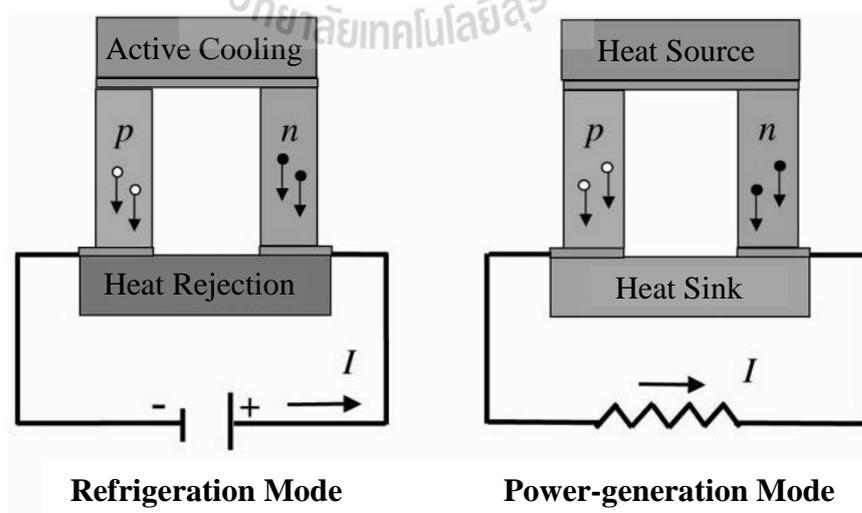

Figure 2.1 Diagram of a thermoelectric device made of n-type and p-type materials in (a) a refrigeration or (b) a power-generation modes (Tritt and Subramanian, 2006).

The performance of a thermoelectric material is defined by the dimensionless figure of merit, ZT;

$$ZT = \frac{S^2 \sigma T}{\kappa} = \frac{S^2 T}{\rho \kappa} \quad (1)$$

where S is the Seebeck coefficient, σ is the electrical conductivity, ρ is the electrical resistivity, κ_T is the total thermal conductivity ($\kappa_T = \kappa_E + \kappa_L$; κ_E and κ_L are the electronic and the lattice contributions, respectively), and T is the absolute temperature. To maximize the ZT value, high S , high σ , and low κ are required (Tritt and Subramanian, 2006). These factors are closely related, such that charge carrier concentration has to be optimized (Weidenkaff *et al.*, 2008). In general, a carrier density of materials in the range of heavily-doped semiconductors exhibits large ZT values as shown in Figure 2.2 (Snyder and Toberer, 2008).

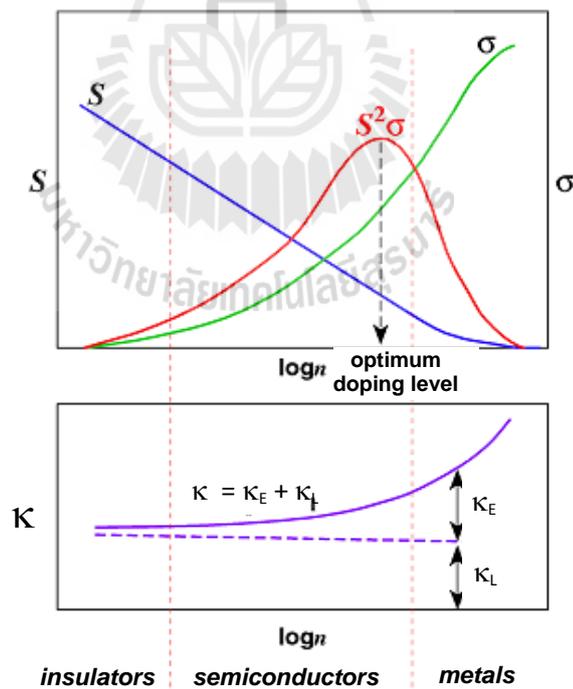

Figure 2.2 Transport properties as a function of a carrier concentration (Ohtaki, 2011).

Besides the high ZT value, the operating temperature of a system is also important for real applications. As shown in Figure 2.3, each material has different

operating temperature and the materials with wider ranges of operating temperatures have more potential for the real applications.

Environmental and beneficial issues have to be considered to develop suitable thermoelectric materials. Compounds such as alloys and chalcogenides have disadvantages because of their poor durability at raised temperature, low abundance, high cost of the comprising elements, and high toxicity. It is therefore necessary to explore new thermoelectric materials to overcome these shortcomings (Ohtaki, 2011).

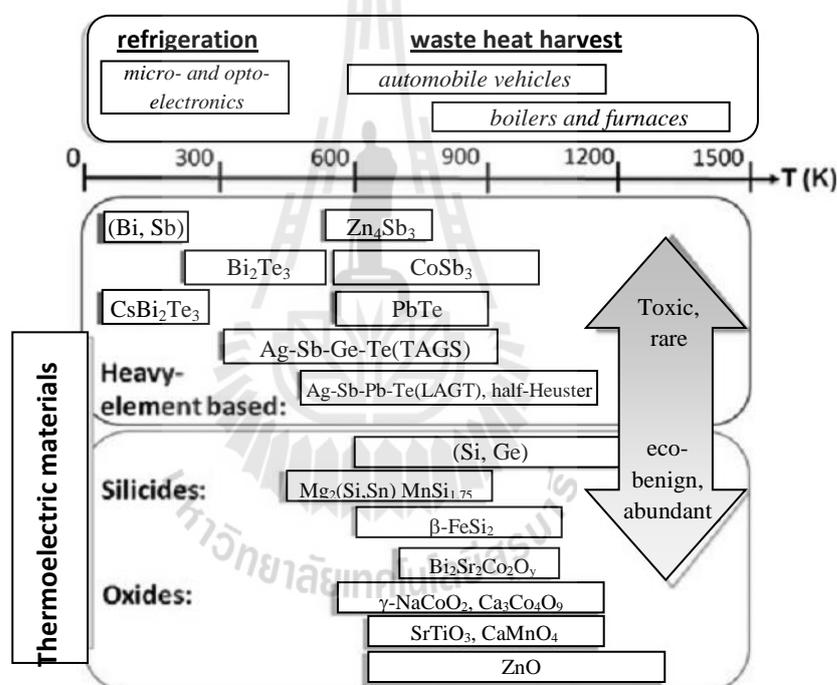

Figure 2.3 Diagrammatic comparisons of diverse thermoelectric materials for the applications as a function of the operating temperature, the abundance, and the toxicity (He *et al.*, 2011).

2.2 LaCoO₃-based thermoelectric oxides

This part discusses the structural details and related researches of the LaCoO₃-related systems.

2.2.1 Structure of LaCoO₃

LaCoO₃ structure is related to perovskite of general formula ABO₃, where A and B are two cations of very different sizes. In its cubic-symmetry structure (Figure 2.4a), B is the smaller cation surrounded by a six-fold coordination of oxygen forming an octahedron while A is the larger cation in a twelve-fold coordination. Each octahedral unit shares corners to form three-dimensional networks with B-O-B and O-B-O bond angles of 180° and 90°, respectively. The body-center position is occupied by the large A cation.

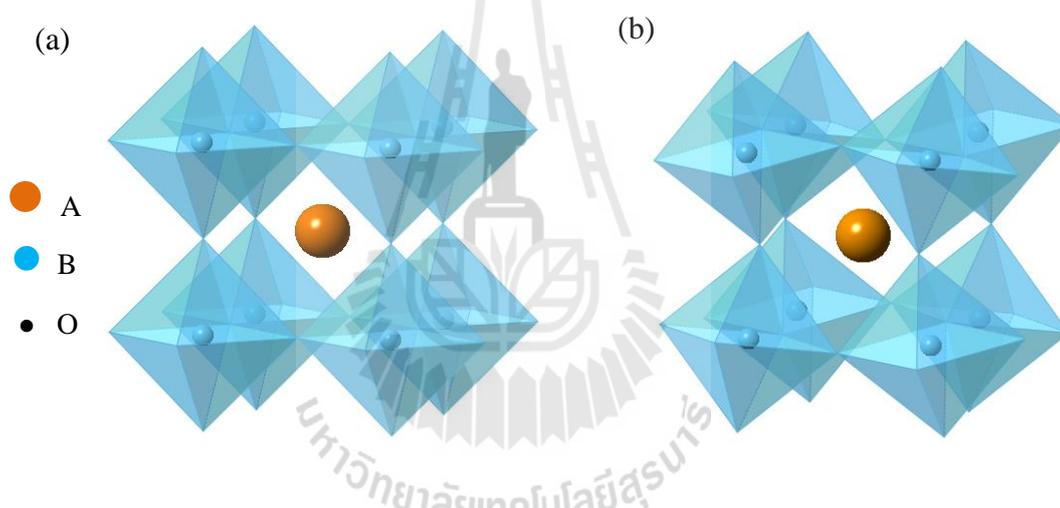

Figure 2.4 (a) a ABO₃ ideal perovskite structure and (b) a distorted perovskite structure.

Certain ratios of the ionic radii of A and B are required to stabilize the perovskite cubic structure. Otherwise, a distortion can lower a symmetry and a coordination number of cations might be reduced (Tejuca and Fierro, 1989). Actually, most perovskites are distorted from the ideal cubic structure by various factors such as the ionic size effects, the deviations from the ideal composition, and the Jahn-Teller effect (Johnsson and Lemmens, 2007). On the basis of the geometric considerations, Goldschmidt (1926) defined the tolerant limits of ionic radii through the tolerance

factor, $t = (r_A + r_O)/[\sqrt{2}(r_B + r_O)]$ where r_A , r_B , and r_O are the radii of A, B, and O ions, respectively. The ideal cubic perovskite SrTiO₃ with $r_{A(Sr)} = 1.44 \text{ \AA}$ and $r_{B(Ti)} = 0.605 \text{ \AA}$, has $t = 1$ (Johnsson and Lemmens, 2007). In comparison, LaCoO₃ has similar B cation size ($r_{B(Co)} = 0.610 \text{ \AA}$) but smaller A cation ($r_{A(La)} = 1.36 \text{ \AA}$) which makes t become smaller than 1. As a result, the BO₆ octahedra tilt in order to fill a space and allow a distorted perovskite structure (Figure 2.4(b)). In fact, a cubic perovskite can be observed only for $0.81 \leq t \leq 1.11$ (Mitchell, 2002).

2.2.2 Thermoelectric properties of LaCoO₃-based oxides

LaCoO₃ is a p-type semiconducting material (Goodenough and Longo, 1970) in which its Seebeck coefficient (thermoelectric power or thermopower) is positive indicating that positive charge is the major carrier (Weidenkaff *et al.*, 2008). The system of LaCoO₃ has been attractive in thermoelectric field because of its high Seebeck coefficient of about $600 \mu\text{VK}^{-1}$ at room temperature (Señarís-Rodríguez and Goodenough, 1995). However, the electrical resistivity is still high (Weidenkaff *et al.*,

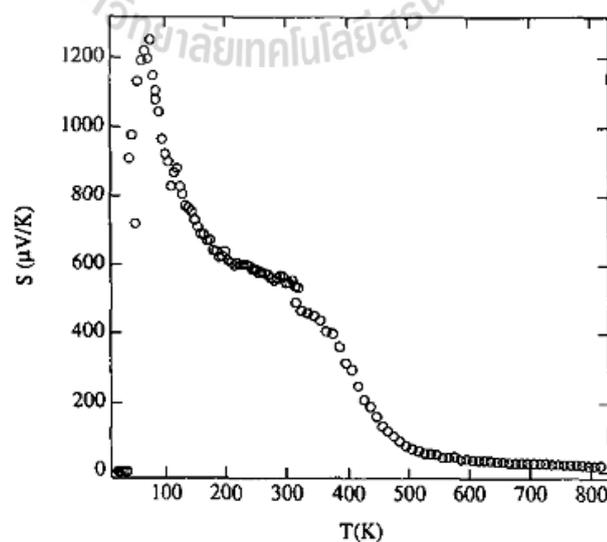

Figure 2.5 Temperature dependence of the Seebeck coefficient of LaCoO₃ ($4.2 \text{ K} < T < 823 \text{ K}$) (Señarís-Rodríguez and Goodenough, 1995).

2008) which would lower the ZT value.

The amount of the charge transports in this system can be tuned by the level of Co-site and/or La-site substitution. Numerous strategies have been attempted to generate materials with high figure of merit, ZT, including increasing thermoelectric power and electrical conductivity as well as decreasing thermal conductivity.

2.2.2.1 Electrical conductivity improvement

Electrical conductivity (σ) or electrical resistivity (ρ) of materials relates to charge carrier concentration (n), electric charge (e), and electron mobility (μ) (Snyder and Toberer, 2008) by

$$\sigma = \frac{1}{\rho} = ne\mu \quad (2)$$

Higher level of charge carrier concentration significantly increases electrical conductivity of oxides. In general, the charge carrier can be divided into two types; a hole and an electron which are dominant in p- and n-type semiconductors, respectively.

A p-type material can be produced by the substitution of parent cation by cations with lower valency which results in generation of positive hole carriers. In LaCoO₃ system, various cations have been utilized for the substitution of La- or Co-site; such as Sr²⁺, Ba²⁺, Ca²⁺, Ni²⁺, and Mg²⁺. La substitution by Sr has received great attention since Androulakis *et al.* (2004) discovered a high figure of merit, ZT, of 0.18 in La_{0.95}Sr_{0.05}CoO₃ at room temperature. In addition, Sr played an important role to almost completely suppress the resistivity of LaCoO₃. Then, the amount of 0.05-0.2 for Sr doping was studied by Zhou *et al.* (2008b) from room temperature to 773 K; higher level of Sr doping resulted in higher electrical conductivity because of the higher carrier concentration. The replacement of La³⁺ by Sr²⁺ creates excess negative

charges in the lattice which are compensated either by oxidation of Co^{3+} to Co^{4+} and hence creates holes or by creation of oxygen vacancies to keep the electroneutrality of compounds (Mineshige *et al.*, 1999). However, the Seebeck coefficients of all samples decreased dramatically in the temperature range below 550 K and remained constant up to 773 K. Yet the highest ZT of 0.046 was obtained with $\text{La}_{0.9}\text{Sr}_{0.1}\text{CoO}_3$. Moreover, thermoelectric properties of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ with $x = 0.01-0.4$ were investigated at 100-1000 K (Iwasaki *et al.*, 2008). It was found that the conductivity increased with increasing Sr content, on the contrary, the Seebeck coefficient was lowered (Figure 2.6-2.7). The same effects were reported in other substitutions both in La site such as Ba (Mandal *et al.*, 2004; Hejtmánek *et al.*, 2004), Ca (Weidenkaff *et al.*, 2008); and in Co substitution such as Ni (Kozuka *et al.*, 2012; Robert *et al.*, 2006; Robert *et al.*, 2007; Vulchev *et al.*, 2012). Although p-type substitution of LaCoO_3 plays an important role in enhancing electrical conductivity, it is usually accompanied by reduction of Seebeck coefficient.

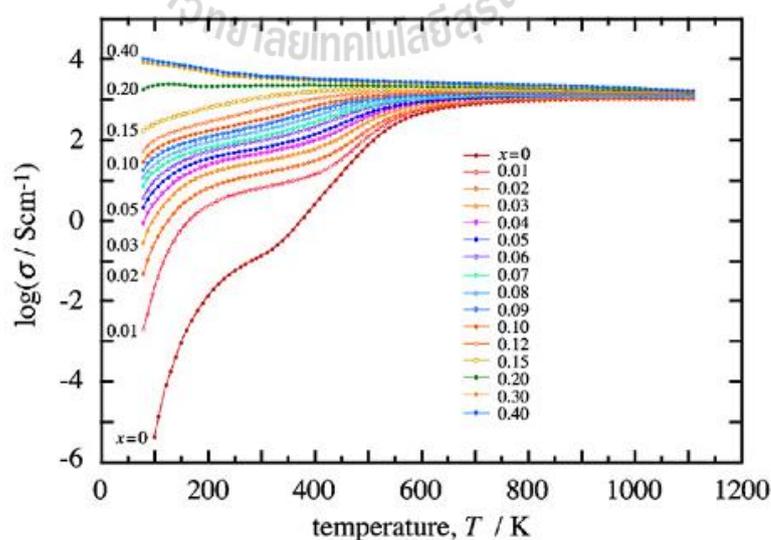

Figure 2.6 Temperature dependence of the electrical conductivity of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ (Iwasaki *et al.*, 2008).

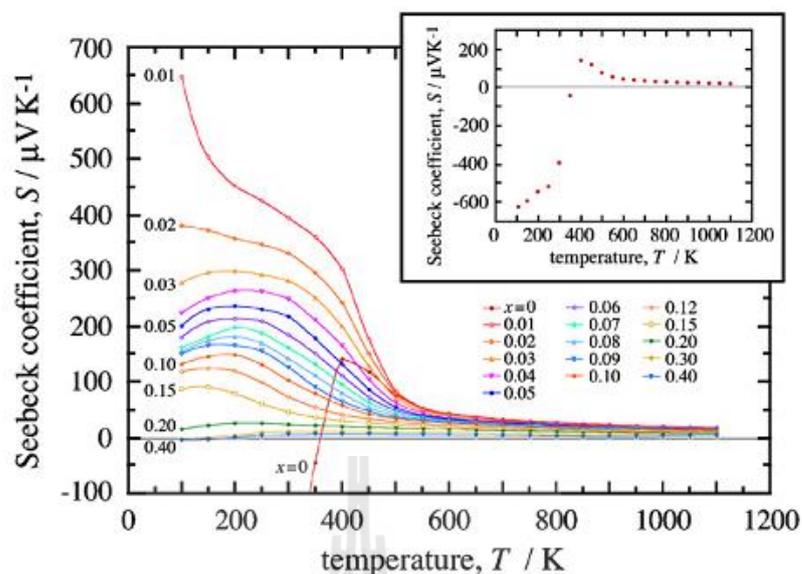

Figure 2.7 Temperature dependence of the Seebeck coefficient for $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$. The inset shows the Seebeck coefficient of non-doped LaCoO_3 (Iwasaki *et al.*, 2008).

An n-type material is generated by a higher valency cations replacement. Excess electrons are created as the carriers. Hébert *et al.* (2007) substituted Ce^{4+} for La-site in LaCoO_3 . Co^{2+} was created by the reduction of Co^{3+} in order to balance total charges of the compound. The electrical resistivity of the Ce-substituted LaCoO_3 was lower than that of LaCoO_3 but still much higher than that of the Sr-doped LaCoO_3 (Figure 2.8).

The lower efficiency in n-type conduction attributes to the hopping mechanism of $\text{Co}^{2+}/\text{Co}^{3+}$ system which is similar to ‘spin-blockade’ mechanism as previously proposed in $\text{LnBaCo}_2\text{O}_{5-\delta}$ (Maignan *et al.*, 2004). The electron carriers in high spin (HS) state of Co^{2+} are impossible to interchange with low spin (LS) of Co^{3+} because of difference in e_g band energy level. Furthermore, Co^{2+} low spin configuration of $t_{2g}^6 e_g^1$ would be unstable. The hopping of one electron of HS Co^{2+} in the LS Co^{3+} matrix is thus forbidden (Hébert *et al.*, 2007) (Figure 2.9).

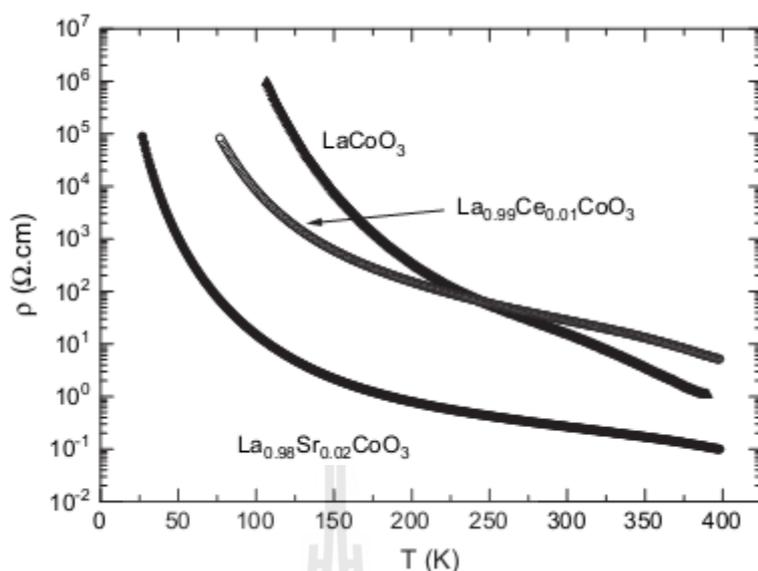

Figure 2.8 Temperature dependence of the electrical resistivity of LaCoO_3 comparing with p-type $\text{La}_{0.98}\text{Sr}_{0.02}\text{CoO}_3$ and n-type $\text{La}_{0.99}\text{Ce}_{0.01}\text{CoO}_3$ (Hébert *et al.*, 2007).

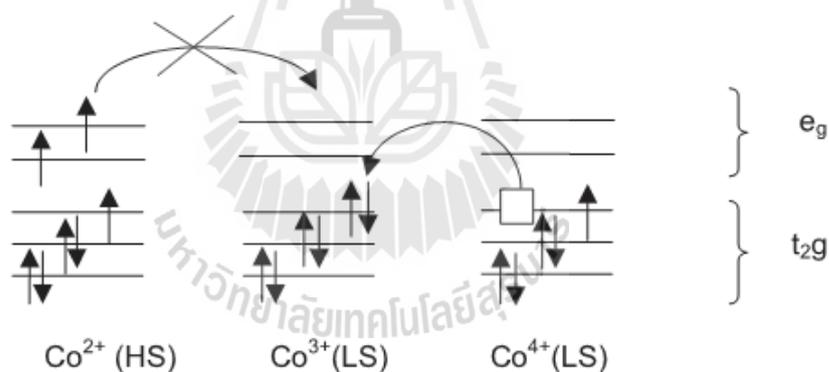

Figure 2.9 Schematic illustration of the transport mechanism in the e_g band ($\text{Co}^{2+}/\text{Co}^{3+}$) and in the t_{2g} band ($\text{Co}^{3+}/\text{Co}^{4+}$) (Hébert *et al.*, 2007).

On the contrary, $\text{Co}^{3+}/\text{Co}^{4+}$ system in p-type LaCoO_3 greatly increases conductivity because the carrier can easily hop between the same low-spin state energy (Hébert *et al.*, 2007).

Partially doping of a Co-site by Ti^{4+} was studied by Robert *et al.* (2006).

It was shown that resistivity increase with Ti content. This is in a good agreement with

the n-type transport mechanism as discussed above. In 2010, Robert *et al.* (2010) studied the wider range of a Ti substitution and found that the electrical resistivity varied with the amount of n-type dopant (Figure 2.10). Furthermore, the reported activation energy (E_a) of this system progressively increases with Ti content which is the reason of a high resistivity.

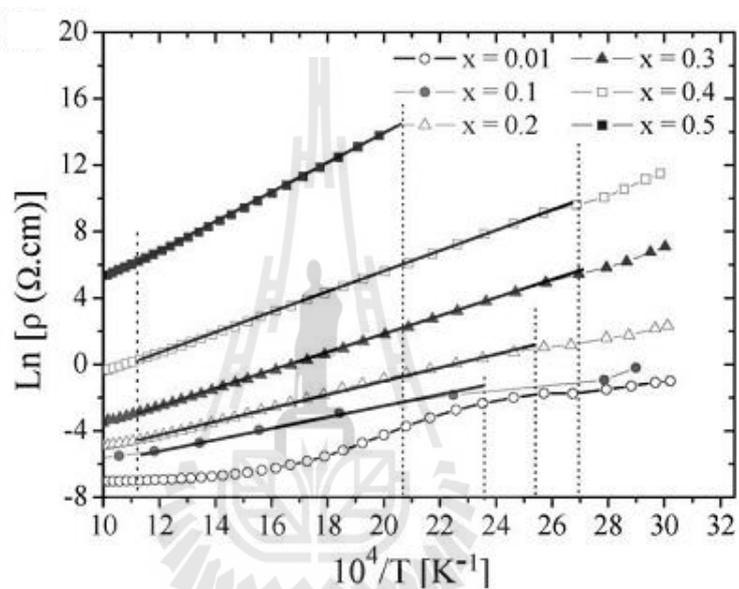

Figure 2.10 Plot of the electrical resistivity in the temperature range of 330 K <math>T < 1273</math> K of $\text{LaCo}_{1-x}\text{Ti}_x\text{O}_3$ ($x = 0.01-0.5$) (Robert *et al.*, 2010).

As the thermoelectric device contains the couple consisting of p-type and n-type components, the improvement of both parts is importantly taken into account for an efficient gadget.

2.2.2.2 Seebeck coefficient improvement

The Seebeck coefficient of cobalt oxides was theoretically studied at a sufficient high temperature by formularizing the Heikes equation as expressed as

$$S = -\frac{k_B}{e} \left[\ln\left(\frac{g_3}{g_4}\right) \left(\frac{x}{1-x}\right) \right] \quad (3)$$

where k_B is Boltzmann constant, e is electric charge, g_3 (g_4) is the number of spin states for Co^{3+} (Co^{4+}), and x is the concentration of Co^{4+} (Berggold *et al.*, 2005; Chaikin and Beni, 1976; Koshibae *et al.*, 2000).

Hund's rule coupling, crystal field splitting energy ($10Dq$), and temperature are related parameters that are used to determine the possible spin state, g_3 (g_4). The degeneracies of both Co^{3+} and Co^{4+} in low-spin state (LS), intermediate-spin state (IS), and high-spin state (HS) were proposed as shown in Figure 2.11. It was stated that the characteristic spin degeneracy and strong correlation of $3d$ electrons in cobalt oxides cause the large Seebeck coefficient. Moreover, the ratios of g_3/g_4 and $x/1-x$ influence not only the magnitude but also the sign of S (Koshibe *et al.*, 2000).

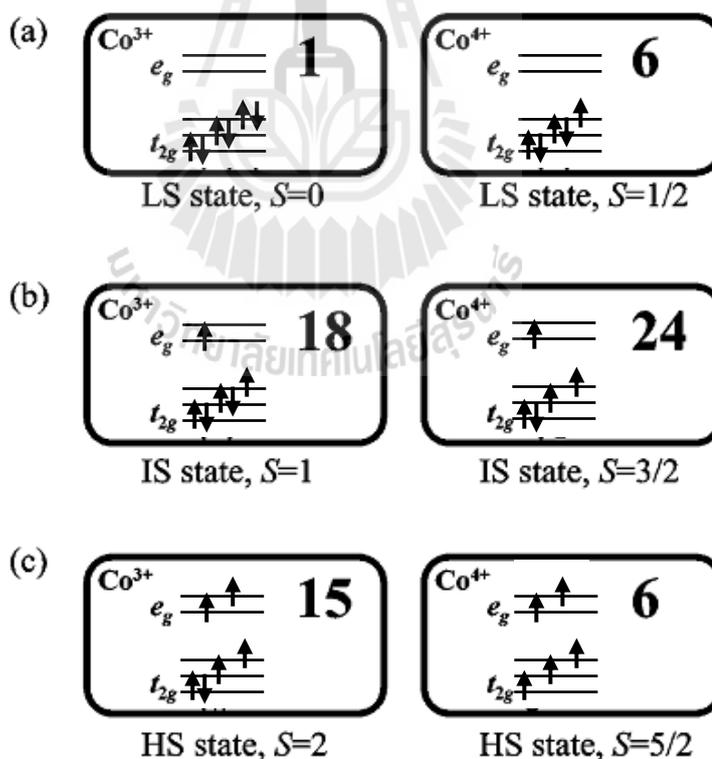

Figure 2.11 Schematic of spin degeneracy of $3d$ electron in Co^{3+} and Co^{4+} at (a) Low-spin state, (b) intermediate-spin state, (c) high-spin state, when degeneracy for each state is presented by the number in the frame and S is a spin multiplicity (modified

from Koshibae *et al.*, 2000).

Substitution with heterovalent cations, e.g., Sr-(Mandal *et al.*, 2005; Zhou *et al.*, 2006; Zhou *et al.*, 2008a; Zhou *et al.*, 2008b; Iwasaki *et al.*, 2008), Ba-(Hejtmánek *et al.*, 2004; Mandal *et al.*, 2004), Ca-(Weidenkaff *et al.*, 2008), and Ni-substitution (Li and Li, 2011; Robert *et al.*, 2008; Kozuka *et al.*, 2012; Vulchev *et al.*, 2012; Robert *et al.*, 2006; Robert *et al.*, 2007) usually increase electrical conductivity and decrease Seebeck coefficients. However, some of replacements such as Ti-(Robert *et al.*, 2010) and Rh-substitution (Li *et al.*, 2010) have opposite effects as they reduce electrical conductivity and raise Seebeck coefficient.

Among these results, Hejtmánek *et al.* (2008) found that the introduction of homovalent Ga³⁺ into Co-site results in similar resistivity and thermoelectric power behavior to LaCoO₃ which showed the Seebeck coefficient of 700 μVK^{-1} at 300 K (Figure 2.12). Heterovalent Mg-doping showed constant thermoelectric power in the same way as 0.02 Sr-doping from 100 to 300 K but with higher Seebeck coefficient of 400 μVK^{-1} at 300 K (Hejtmánek *et al.*, 2008). The Seebeck coefficient increases with Mg substitution but the values fall rapidly as the temperature increases (Ramadass *et al.*, 1979). Another interesting dopant which showed ability to maintain a high Seebeck coefficient is Fe. LaCo_{1-x}Fe_xO₃ (x = 0-0.5) can maintain Seebeck coefficient about 600 μVK^{-1} at room temperature (Vulchev *et al.*, 2012).

2.2.2.3 Thermal conductivity improvement

Electrical conductivity can be improved with various heterovalent substitutions, some of which can also maintain thermoelectric power. In addition, the ZT can be further maximized by minimizing thermal conductivity. This could be achieved by means of adjusting the crystallographic structure and increasing the

phonon scattering.

Total thermal conductivity (κ_T) comes from two sources: electronic (κ_E) and lattice (κ_L) part. κ_E is directly related to the electrical conductivity through the Wiedemann–Franz law:

$$\kappa_E = \sigma LT = ne\mu LT \quad (4)$$

where L is the Lorenz factor which is equal to $2.4 \times 10^{-8} \text{ J}^2\text{K}^{-2}\text{C}^{-2}$ for free electrons.

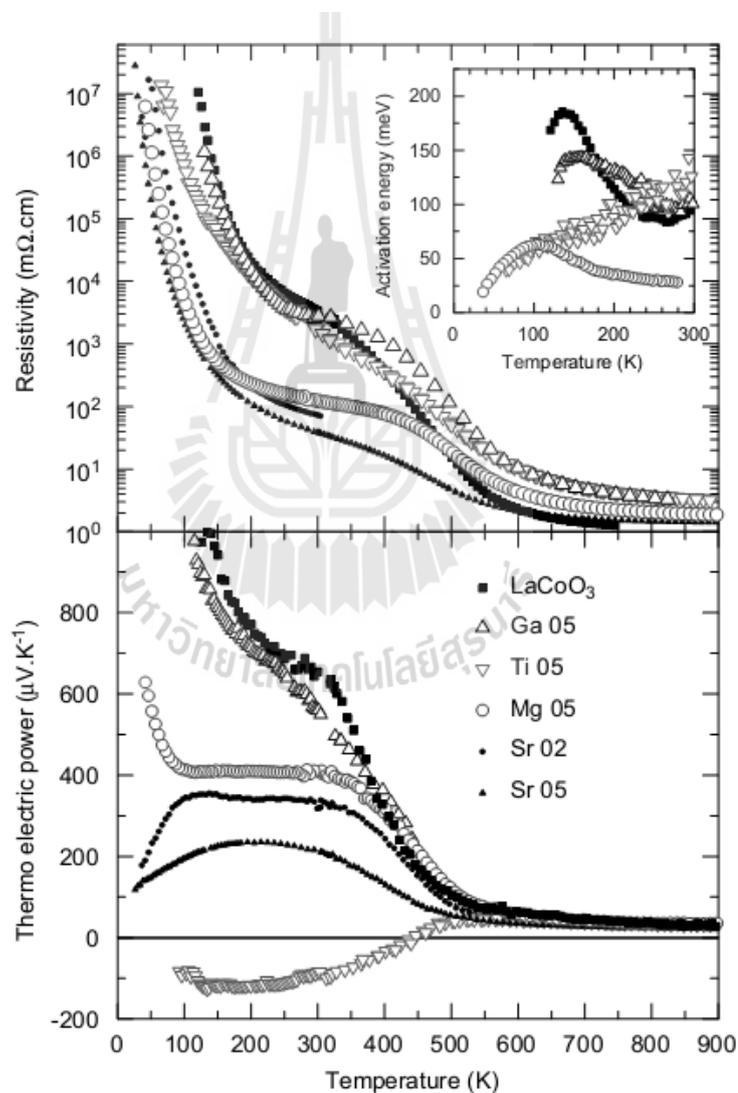

Figure 2.12 The electrical resistivity and the thermopower for $\text{LaCo}_{1-x}\text{M}_x\text{O}_3$ ($x = 0.02, 0.05$) when M is Ga, Ti, Mg, and Sr compared to LaCoO_3 . Inset shows activation energy in the low-temperature region (Hejtmánek *et al.*, 2008).

Regarding this equation, the substitution which enhances the charge carrier concentration will simultaneously increase electronic thermal conductivity (κ_E). Therefore, the alternative way is to reduce the lattice part of the thermal conductivity (κ_L). When all the phonons have a mean free path intrinsically equal to the interatomic spacing of the constituent atoms, scattering phonons is attempted by creating rattling structures, alloying, grain-boundary scattering (due to the size of the grains) or point defects such as interstitials and vacancies (Snyder and Toberer, 2008; Tritt and Subramanian, 2006).

There have been several investigations into the enhancement of short wave phonon scattering by point defects; for example, Sr-(Zhou *et al.*, 2006), Pb-, and Na-substitution (He *et al.*, 2006) lower thermal conductivity of LaCoO_3 . Iwasaki *et al.* (2008), however, discovered that the thermal conductivity reduction of Sr-doping is limited with the doping concentration range of 0-0.04; when Sr content is increased (0.05-0.4), the values increase with amount of carriers (Figure 2.13). Likewise, Ni doping up to 0.2 showed increasing thermal conductivity (Li and Li, 2011).

Apart from conventional ceramic method, Iwasaki *et al.* (2008) prepared $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ with a polymerized complex method and found that thermal conductivity was improved depending on Sr concentration in the range of 0-0.2 (Zhou *et al.*, 2008b). These results show that the thermal conductivity mainly comes from its morphology structure. This implies that it is possible to increase the figure of merit ZT by optimizing compositions and microstructure in order to enhance phonon scattering, hence reduce thermal conductivity (Zhou *et al.*, 2008b). Other solution methods and sol-gel method were carried out to investigate the changes of thermal conductivity comparing to solid state reaction. Although the samples prepared by sol-gel processes

have better homogeneity and smaller average particle size, they have higher thermal conductivity than that of a solid state reaction because of their higher density. However, large ZT value of 0.046 is obtained in sol-gel sample of $\text{La}_{0.9}\text{Sr}_{0.1}\text{CoO}_3$ at room temperature (Zhou *et al.*, 2008a).

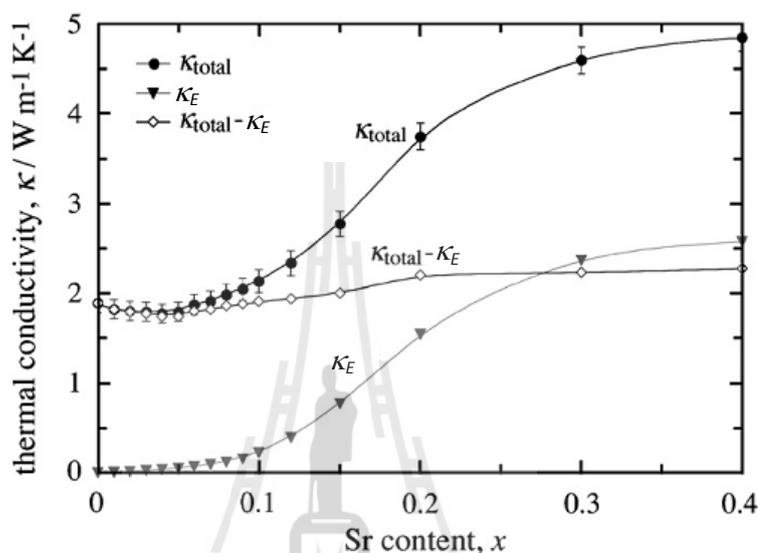

Figure 2.13 Thermal conductivity of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ dependence of Sr content at 300 K (Iwasaki *et al.*, 2008)

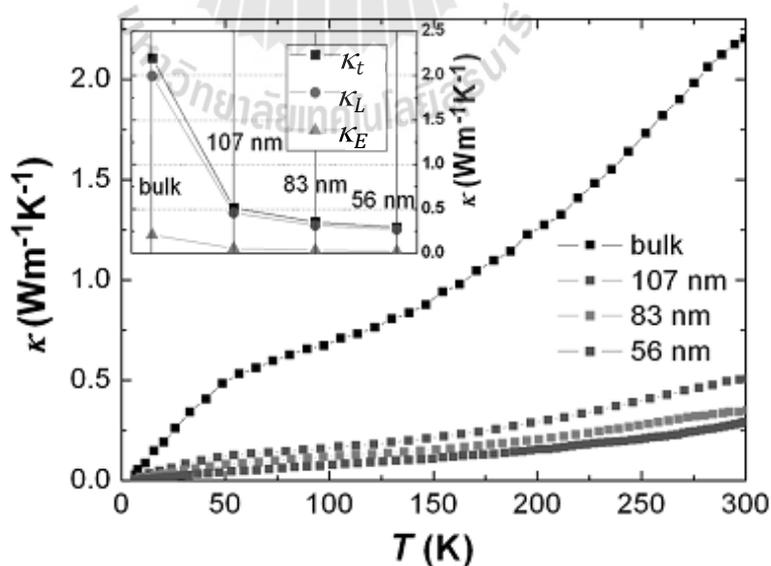

Figure 2.14 Temperature dependence of the thermal conductivity, κ , of the bulk and nanowires $\text{La}_{0.9}\text{Sr}_{0.1}\text{CoO}_3$. The inset presents the room-temperature κ_t , κ_L , and κ_E (Wang and Fan, 2010).

In addition, a hydrothermal method was used to prepare thermoelectric samples by Wang and Fan (2010). The nanowire samples exhibit strong suppression of thermal conductivity (Figure 2.14) and the samples with optimal size have a ZT value which is nearly two time higher than that of the bulk (Figure 2.15) (Wang and Fan, 2010).

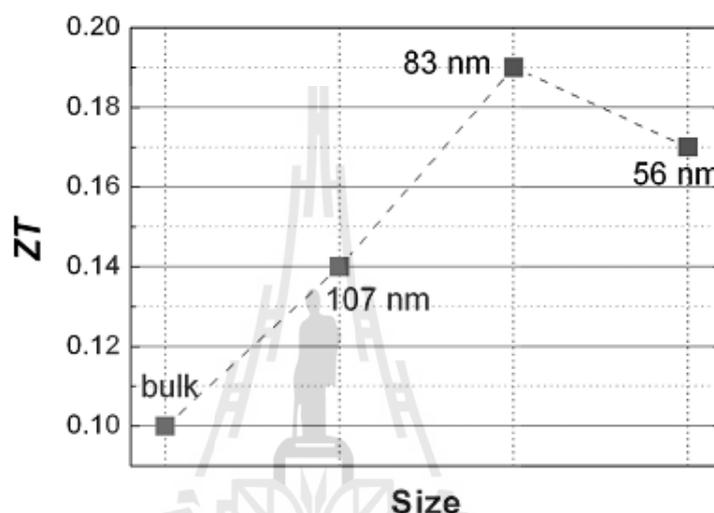

Figure 2.15 Plot of the ZT value versus the size of $\text{La}_{0.9}\text{Sr}_{0.1}\text{CoO}_3$ (Wang and Fan, 2010).

2.2.2.4 ZT improvement strategy

Since LaCoO_3 -based oxides have been studied extensively for decades, the state-of-the-art researches are to maximize the dimensionless figure of merit ZT by substitutions. However, most works have mainly focused on single substitution for the La or Co site which leads to improvement of only one or two parameters against the other(s). As each substitution has different effects, the new idea of the double substitutions was introduced in an attempt to maximize the positive effects on as many parameters as possible.

In initial attempts, Sr substitution for La site and Mn substitution for Co site, $\text{La}_{0.80}\text{Sr}_{0.20}\text{Co}_{1-y}\text{Mn}_y\text{O}_3$ ($y = 0.01-0.10$) were conducted. Sr plays an important

role in enhancing electrical conductivity while Mn can both increase Seebeck coefficient and reduce thermal conductivity. As a result, a large ZT was obtained at room temperature (Suzuki *et al.*, 2003). After that, $\text{La}_{0.95}\text{Sr}_{0.05}\text{Co}_{1-x}\text{Rh}_x\text{O}_3$ ($x = 0.1-0.3$) was also prepared. In spite of a slight increase in resistivity, Rh together with Sr can maintain Seebeck coefficient and remarkably reduce thermal conductivity providing a new route to achieve a higher ZT at higher temperatures (300-800 K) (Kwong *et al.*, 2010). Lately, double substitution in the same site, $\text{LaCo}_{0.8}(\text{Ni}_{0.1}\text{Fe}_{0.1})\text{O}_3$, showed improved transport properties and exhibits the great thermoelectric efficiency with ZT of 0.16 at room temperature (Vulchev *et al.*, 2012).

These findings provide new insights into an improvement of the thermoelectric perovskite oxides. The concept of the double substitution as well as sample preparation method will be very useful in achieving high thermoelectric efficiency of LaCoO_3 -based oxides.

EXPERIMENTAL

3.1 Chemicals

- Citric acid monohydrate ($C_6H_8O_7 \cdot H_2O$), 99.5-105.5%, Carlo Erba
- Cobalt(II) nitrate hexahydrate ($Co(NO_3)_2 \cdot 6H_2O$), 99+%, Acros Organic
- Lanthanum(III) nitrate hexahydrate ($La(NO_3)_3 \cdot 6H_2O$), 99.999%, Acros Organic
- Magnesium(II) nitrate ($Mg(NO_3)_2 \cdot 6H_2O$), 99.5%, Qręc
- Strontium(II) nitrate ($Sr(NO_3)_2$), 99+%, Acros Organic

3.2 Instruments

- Simultaneous thermal analyzer (STA), Model STA449 F3, NETZSCH
- Fourier transform infrared spectrometer (FT-IR), Model Spectrum GX, Perkin-Elmer
- Powder X-ray diffractometer (XRD), Model D2 Phaser, Bruker
- Field emission scanning electron microscope (FESEM), Model JSM-7800F, JEOL/Energy dispersive X-ray spectroscopy (EDS), Model X-Max 50 mm, Oxford instruments
- Physical properties measurement system (PPMS), Quantum Design

3.3 Sample preparation

3.3.1 Sol-gel method

Sol-gel method is a good method to improve homogeneity of a sample as the reagents are well-mixed on an atomic scale. The precursors of metal salts are dissolved giving a colloidal solution named 'sol'. The gel can be formed by a dehydration process of the sol. After drying and calcination, a final product is obtained. Another good point of this preparation technique is that heating temperature is usually decreased (Segal, 1997).

In this work, polycrystalline samples of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$, $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.02, 0.05, 0.1, 0.2$), and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.025, 0.05, 0.1$) were prepared by the citrate sol-gel method. High purity starting materials of $\text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$, $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$, $\text{Sr}(\text{NO}_3)_2$, and $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ were weighed in a stoichiometric ratio and dissolved in a citric acid solution with 1:4 molar ratio (cations: citric acid). The aqueous solution was heated with constant stirring at 353 K for 2 hours resulting in a red transparent solution. Then the solution was dried at 393 K in air in an oven overnight to transform into a dried gel. The obtained dried gel was ground and calcined at 1023-1073 K for 8-12 hours at a heating rate of 5 K/min to give a black powder. The calcined powder was ground, pressed into a pellet, and then sintered at 1273 K for 24 hours in air. A bar-shaped sintered-pellet with general dimensions of about 10 mm x 3 mm x 2 mm was prepared for the thermoelectric properties measurement

3.4 Characterizations

3.4.1 Structure identifications

3.4.1.1 Thermogravimetry/Differential thermal analysis (TG/DTA)

Thermogravimetric technique monitors the change in weight of a sample as a function of temperature or time in a controlled atmosphere. Each change in weight refers to the decomposition of the components of a compound at each temperature. When the compounds have no change, weight of a sample remains constant with increasing temperature. In this study, thermogravimetry analysis (TGA) was used to investigate the decomposition of substances and to find the temperature required to decompose all organic species in the samples prepared by the sol-gel method in order to determine the calcining temperature.

Differential thermal analysis technique measures the difference in temperature, ΔT , between a sample and an inert reference material as a function of temperature; therefore, detects changes in heat content, that is, enthalpy. Changes in samples relative to the reference are either endothermic or exothermic. Thus, a DTA curve provides data on the heat changes that an involved chemical reaction have. The DTA curve was utilized for this purpose in this study.

Thermal decomposition of the dried gels was investigated by TG/DTA using a NETZSCH STA449 F3 Simultaneous Thermal Analyzer instrument (STA). The dried gel was put in an Al_2O_3 crucible and heated from 303 K to 1273 K with a heating rate of 10 K/min under the atmosphere of 80% nitrogen and 20% oxygen.

3.4.1.2 Fourier transform infrared spectrometer (FT-IR)

This spectroscopic technique is related with the infrared radiation; some of infrared radiation is absorbed by the sample and some of it is transmitted. The absorption of infrared at specific frequencies is characteristic to vibrations between bonds of the atoms. An infrared spectrum represents a fingerprint of a sample and can be shown in either the absorption or transmission mode.

In this study, FT-IR was used to probe the structural information of the samples. The presence of specific peaks in the infrared spectra was used to confirm the functional groups of the obtained products.

In the experiment, FT-IR spectra were obtained by a model spectrum GX Perkin-Elmer IR spectrometer. The sample was mixed with dry KBr and pressed to form a pellet for the measurement. Spectra were collected in the range $4000-400\text{ cm}^{-1}$ using 32 scans with a resolution of 4 cm^{-1} .

3.4.1.3 X-ray diffraction (XRD)

X-ray diffraction is a principal technique of solid state chemistry, which is widely used for crystal structure determination and phase identification. In principle, a monochromatic beam of X-rays, which strikes the powder of a solid, interacts with electrons in matter in which it is scattered in various directions by the electron cloud of the atoms. Referring Bragg's equation ($n\lambda = 2d\sin\theta$), the constructive interferences occurred with scattered X-rays which are in phase and contribute to X-ray powder diffraction patterns. Each solid material has its own characteristic X-ray powder diffraction pattern.

In this study, the X-ray powder diffraction patterns were used as a fingerprint of samples for phase identification and phase purity confirmation. When a

pure phase of a compound is obtained, the investigation of a crystal structure is necessary. Crystallographic information such as cell parameters can be calculated from positions or *d*-spacings of the set of peaks.

In this work, XRD patterns of all samples were collected at room temperature on a model D2 Phaser of Bruker X-ray diffractometer. To check a phase purity, the operation uses Cu K α radiation ($\lambda=0.15406 \text{ \AA}$) with 30 mV and 10 mA scanning in diffraction angle (2θ) range of 20-80° at the rate of 0.5°/s and the increment of 0.02°. The phase identification and the crystal structure were determined using PDF-2 (2004) database and EVA software. To analyze unit cell parameters of the samples, the Le Bail structure refinement method was performed with TOPAS software using the high quality XRD patterns collected with the diffraction angle (2θ) from 20° to 120° using the increment of 0.01 at the scan speed of 1°/s.

3.4.1.4 Field Emission Scanning Electron Microscope (FESEM)/ Energy Dispersive X-ray Spectroscopy (EDS)

This electron microscopy provides the microstructural information on the surface of a sample. In FESEM, the gun typed field emission (FE) is applied which gives an electron beam with high-brightness and better focus. With the same principle as other SEM, a sample is bombarded with high-energy electrons from a source called electron gun. A secondary electron is generated to construct the image of a sample's morphology. By the electron bombardment, X-ray energy is also produced by the replacement of an outer-shell electron for a hole when an absorbed electron is rejected out of an atom. This characteristic X-ray emission relates to the type of an atom and is detected in EDS technique. Thus, a quantitative analysis of an element can be investigated (Smart and Moore, 2005; West, 2014).

The purpose of this study was to determine the amount of each element in the sample. The sintered bars of all samples were coated with a layer of gold to make them electrically conduct. All FESEM images were taken with a magnification of 5,000 to 30,000 using the accelerating voltage of 15 kV. A working distance of 10 mm was used with a resolution of 1 nm. By using EDS, the point and ID analysis was performed to capture the interested area of the image to study an elemental composition.

3.4.2 Thermoelectric properties characterizations

Thermoelectric measurements, including electrical resistivity (ρ), Seebeck coefficient (S), and thermal conductivity (κ), were performed on sintered pellets in a Quantum Design Physical Properties Measurement System (PPMS) coupled with the thermal transport option (TTO). The measurements were done at room temperature. The dimensionless thermoelectric figure of merit, ZT , was determined based on the algebraic combination, $ZT = (S^2/\rho\kappa)T$.

3.4.2.1 Physical properties measurement system (PPMS)

Electrical resistivity is one of the important transport properties of a material which is used to determine how well the material can electrically conduct. Moreover, the range of electrical resistivity indicates the type of materials as insulator, semiconductor, or metal (Elsheikh *et al.*, 2014). With the TTO system, a digital signal processor (DSP) current is used as a source and phase sensitive voltage is used as a detection system. The standard four-probe method is employed for the measurement with AC transport mode. The advantage of the four-probe method is that it can prevent the problem from a contact resistance occurred in a two-probe configuration (Quantum Design, 2002).

Seebeck coefficient provides the information about the thermal diffusion of free charge carriers, which can be an electron or a hole. According to the Seebeck effect, charge carrier diffusion generates an electric field inside a material which creates a voltage gradient when a temperature gradient is applied. The TTO system measures Seebeck coefficient by originating a particularized temperature difference (ΔT) and monitoring an electrical voltage difference (ΔV) (Quantum Design, 2002). The ratio of these two measured parameters ($\Delta V/\Delta T$) is equal to S (Tritt and Subramanian, 2006).

The measurement of thermal conductivity evaluates the ability of a material to conduct heat. In the TTO system, the heater source applies heat to a sample and the amount of heat passes through the sample is collected from the observed temperature drop. Thus, thermal conductivity can be calculated directly from three parameters: an applied heater power, a resulting ΔT , and a sample dimension (Quantum Design, 2002).

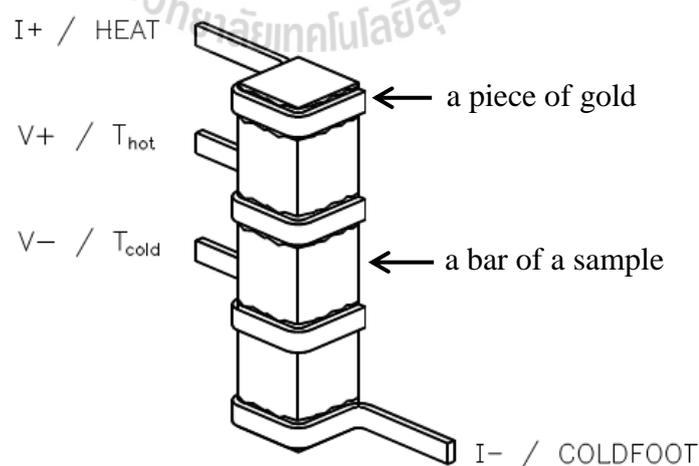

Figure 3.1 The sample preparation for the four-probe measurement (Quantum Design, 2002).

The samples were prepared for a four-probe measurement. The bars of all samples were mounted with four rectangular pieces of gold using an electrically conducting silver-filled epoxy (Figure 3.1). Then, they were undergone baking at about 423 K for around 5 minutes to allow all pieces of gold to attach properly to the surface of samples. To set up a sample for the measurement, firstly, the prepared bar

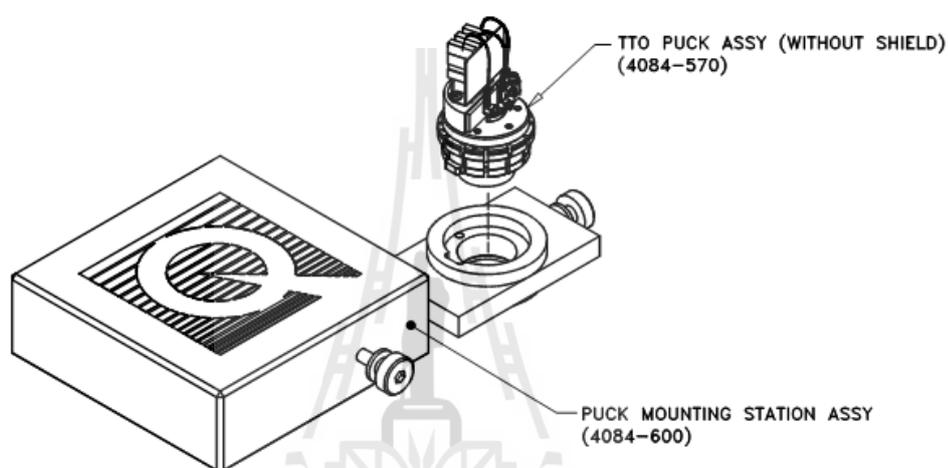

Figure 3.2 The puck-mounting station for a sample preparation (Quantum Design, 2002)

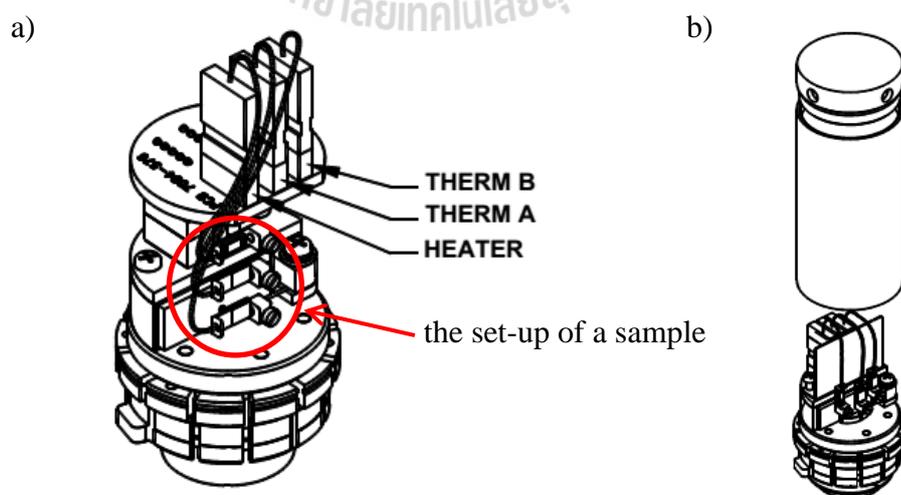

Figure 3.3 The thermal transport sample puck (TTO puck) demonstrating (a) the set up of a sample, (b) TTO puck with a radiation shield (Quantum Design, 2002).

of samples was set into the thermal transport sample puck (TTO puck) (Figure 3.3a) using the puck-mounting station (Figure 3.2). Then, the TTO puck was plugged into the puck-wiring test station in order to check an electrical contact by checking contact at V+/V- and I+/I- with an ohmmeter. After that, the TTO puck was covered with a radiation shield (Figure 3.3b) and then was plugged into the 12-pin socket which is located at the bottom of the PPMS sample chamber (Quantum Design, 2002).

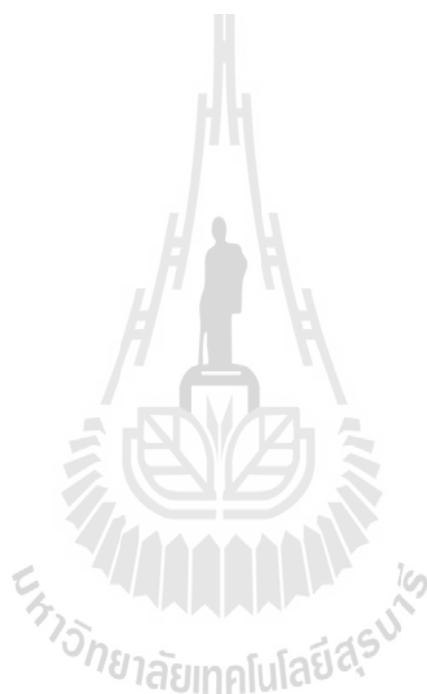

The measurement was done under hi-vacuum system and controlled by the TTO software. Electrical resistivity (ρ), Seebeck coefficient (S), and thermal conductivity (κ), were measured simultaneously and the figure of merit ZT was calculated. By using the TTO software, the units of all parameters were recorded as $\Omega\text{-m}$, μVK^{-1} , and $\text{Wm}^{-1}\text{K}^{-1}$ for ρ , S, and κ , respectively. So, ZT is reported as dimensionless (Quantum Design, 2002).

CHAPTER IV

RESULTS AND DISCUSSION

4.1 Sample preparation

In this work, all samples of LaCoO_3 -based oxides, which are $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$, $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.02, 0.05, 0.1, 0.2$), and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.025, 0.05, 0.1$), were synthesized by the citrate sol-gel method. The sol-gel technique involves four main mechanisms: hydrolysis, polymerization, drying, and densification (Rao and Raveau, 1988). In case of metal oxides, a metal alkoxide is normally used as a precursor (Put, 1998). In this experiment, a citric acid was used as a chelating ligand to form the metal alkoxide (Predoana *et al.*, 2009). The mechanism of LaCoO_3 was proposed by Predoana *et al.* (2009), that of Sr-doped and Mg-doped LaCoO_3 in this work can be proposed based on the same way as shown in following steps:

Firstly, the starting materials of metal nitrates were dissolved in water producing a small particle of metals suspended in an aqueous solution, a system called “sol” (Rao and Raveau, 1988). A metal is solvated by six molecules of water resulting in the hydrate form. This process is called “hydrolysis”.

Secondly, with the presence of citric acids, the water condensation of the metal hydrate is occurred. Citric acids begin to chelate with metal ions forming the coordination compound. This corresponds to “gel” formation because of the aggregation of those particles in the sol (Rao and Raveau, 1988).

Then, the condensation proceeds continuously as citric acids chelate all metals

forming the complex. The metal network is growing during this process and this step is, therefore, called “polymerization”.

After that, the metals-citric acid chelate dries resulting in a dried gel, xerogel or aerogel, depending on the purpose of applications (Rao and Raveau, 1988). Finally, the densification procedure, such as pelletizing and sintering, is applied for specific uses. (Livage et al., 1988)

4.2 Sample characterization

4.2.1 Thermogravimetry/Differential thermal analysis (TG/DTA)

Thermal behavior of the $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.975}\text{Mg}_{0.025}\text{O}_3$ dried gel was investigated by TG/DTA (Figure 4.1). As all the samples are LaCoO_3 -based oxides, $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.975}\text{Mg}_{0.025}\text{O}_3$ was used as a representative. The mechanism of phase changes of dried gel precursor was investigated by weight loss (%) as a function of temperature from 303 K to 1273 K. The weight changes are observed at temperature lower than 873 K which are related to the thermal decompositions of water, citrate precursors, carbon monoxide, and carbon dioxide (Robert *et al.*, 2007). There was no weight loss observed at higher temperature. There are approximately three stages of weight loss. The first endothermic loss of weight occurred at 303-453 K is related to the evaporation of crystalline water. The major weight loss was observed between 453 K and 643 K, which corresponds to the decomposition of citrate precursors (Robert *et al.*, 2007). Changes in DTA at these temperatures are small which suggests that these reactions involved much smaller energy changes compared with those at the last stage. The last stage of weight loss of 27.25% at 723 K accompanied by a strong exothermic DTA peak is ascribed to the loss of remaining organic components, where carbon

monoxide and carbon dioxide was released. As the measurement was performed under 80%N₂/20%O₂ atmosphere, decomposed organic species combusted in the presence of oxygen giving the large exothermic DTA peak (Wu *et al.*, 2011). The weight loss steps from TGA along with the DTA peaks show that the stepwise thermal decomposition of the precursors completes at 873 K. The total weight loss was 78.02%.

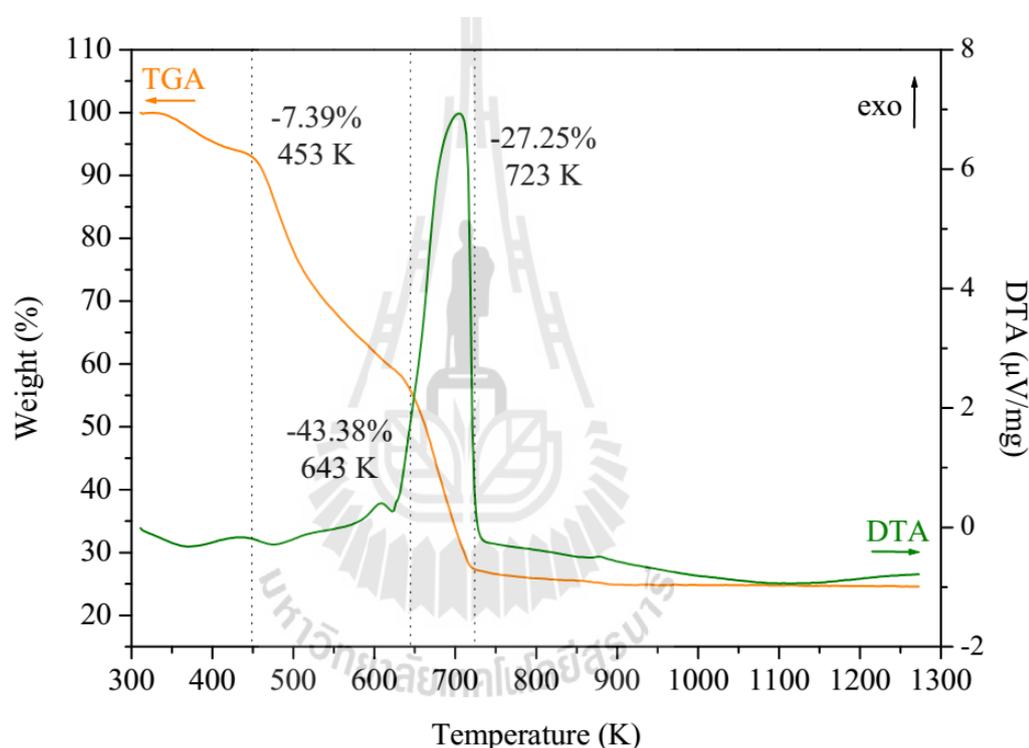

Figure 4.1 TG/DTA curves of the dried gel La_{0.975}Sr_{0.025}Co_{0.975}Mg_{0.025}O₃.

4.2.2 Fourier transform infrared spectrometer (FT-IR)

Figure 4.2 shows the FT-IR spectra of the La_{0.975}Sr_{0.025}Co_{0.975}Mg_{0.025}O₃ samples. The observed peaks are assigned to vibrations of molecular bonds and indexed as shown in the figure. The FT-IR spectrum of citric acid shows functional groups characteristics of carboxylic group. The broad band around 3433 cm⁻¹ is assigned to O-H stretching (Pavia *et al.*, 2009), while the doublets at 1767 cm⁻¹ and 1713 cm⁻¹ are

attributed to stretching vibrations of free carboxylic groups and carboxylic groups forming intramolecular hydrogen bond, respectively (Cannas *et al.*, 2006). Absorption bands at 1630 cm^{-1} and 1412 cm^{-1} are due to asymmetric and symmetric stretching of resonance O-C=O vibrations, respectively (Worayingyong *et al.*, 2008). The FT-IR spectrum of the dried sample exhibits some similar absorption bands with lower intensities. The O-H stretching at 3433 cm^{-1} might belong to some free carboxylic group or moisture. The C=O and two O-C=O stretching vibrations shift to 1719 cm^{-1} , 1633 cm^{-1} , and 1407 cm^{-1} , respectively in the dried sample. These shifts indicate the coordination between metal ions and carboxylic group of citric acids (Preoana *et al.*, 2009).

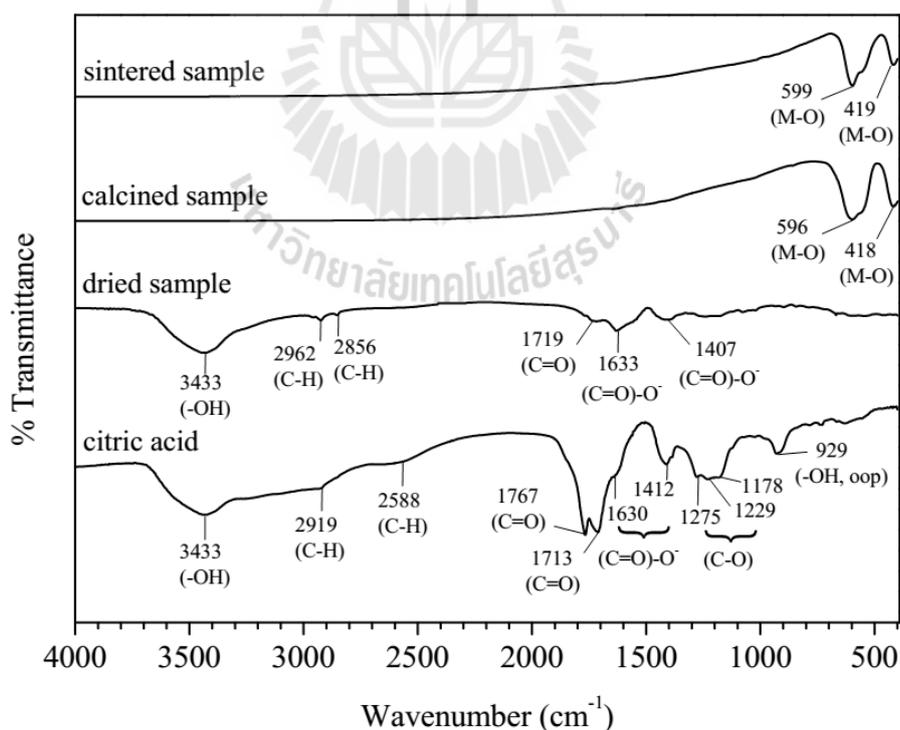

Figure 4.2 FT-IR spectrum of the dried gel, calcined, and sintered sample of $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.975}\text{Mg}_{0.025}\text{O}_3$, and citric acid.

The FT-IR spectrum of the calcined sample shows the evolution of the compound after a heat treatment at 1023 K. The spectrum presents the absence of the bands corresponding to the components of citrate precursors while metal-oxide bonds (M-O) vibrations around 400-600 cm^{-1} are observed which indicates the formation of oxides. The bands at 596 cm^{-1} (very strong) and 559 cm^{-1} (shoulder) are attributed to Co-O stretching while the band at 419 cm^{-1} (strong) corresponds to Co-O bending (Couzi and Huang, 1974; Merino *et al.*, 2005). These bands are also detected at similar wavenumbers in the spectrum of the sintered sample. The fact that only bands for metal-oxide bonds are present in the calcined and sintered samples indicates that all organic species have completely decomposed.

4.2.3 X-ray diffraction (XRD)

The XRD patterns of sintered $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ ($x = 0.02, 0.05, 0.1, 0.2$), $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0.02, 0.05, 0.1, 0.2$), and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0.025, 0.05, 0.1$) samples are shown in Figures 4.3, 4.4, and 4.5, respectively. The diffraction peaks of all samples can be indexed as the LaCoO_3 phase which has a rhombohedral distorted-perovskite structure with the $R\bar{3}c$ space group (PDF 48-0123). The calculated cell parameters a and c are listed in Table 4.1. In general, the partial substitutions of Sr^{2+} for La^{3+} and Mg^{2+} for Co^{3+} cause increases in unit cell parameters because the ionic radii of Sr^{2+} (1.18 Å) and Mg^{2+} (0.72 Å) are greater than those of La^{3+} (1.032 Å) and Co^{3+} (0.545 Å for low-spin and 0.61 Å for high-spin configurations) (Shannon and Prewitt, 1969; Shannon, 1976). The situation could be complicated, however, when the following two issues are taken into account. First, some Co^{3+} ions are oxidized to Co^{4+} ions with a smaller ionic radius (0.53 Å) to preserve the charge neutrality. Secondly, Co^{3+} in this system can be either in the high-,

intermediate-, or low-spin state or even in a mixture of them (Li *et al.*, 2010; Kriener *et al.*, 2004). As shown in Figure 4.6, the substitutions of both cations have more effects on cell parameter c than on cell parameter a , indicating that the unit cell elongates along the c axis with increasing cation substitution content. This tendency is similar to that observed in $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ prepared by other works (Iwasaki *et al.*, 2008; Mineshige *et al.*, 1996). The plot of the c/a ratio is shown in Figure 4.6c to confirm that substitutions were successful (Zhou *et al.*, 2008b).

Based on the ionic radius, Goldschmidt defined the tolerance factor (t), $t = (r_{\text{A}+\text{r}_{\text{O}}})/\sqrt{2}(r_{\text{B}+\text{r}_{\text{O}}})$, to determine the degree of a structural distortion of cubic perovskite (ABO_3). To illustrate the ideal perovskite structure, SrTiO_3 has $t = 1$; the calculation was done using $r_{\text{A}(\text{Sr})} = 1.44 \text{ \AA}$, $r_{\text{B}(\text{Ti})} = 0.605 \text{ \AA}$, and $r_{\text{O}} = 1.40 \text{ \AA}$ (Wells, 2008; Müller, 1993). In case of LaCoO_3 , B cation size is similar ($r_{\text{B}(\text{Co})} = 0.545\text{-}0.61$

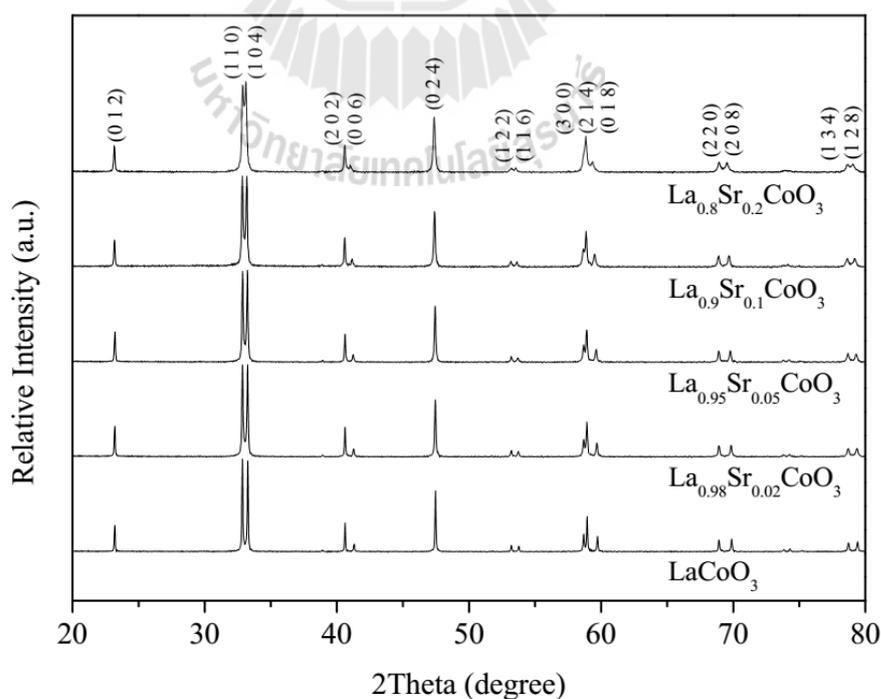

Figure 4.3 XRD patterns of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ ($x = 0.02, 0.05, 0.1, 0.2$).

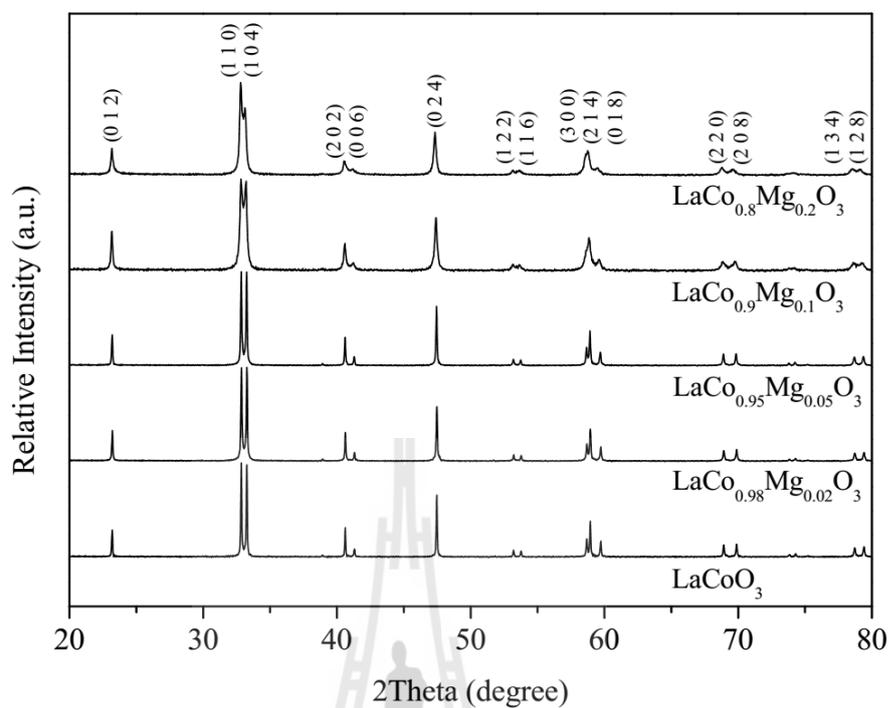

Figure 4.4 XRD patterns of $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0.02, 0.05, 0.1, 0.2$).

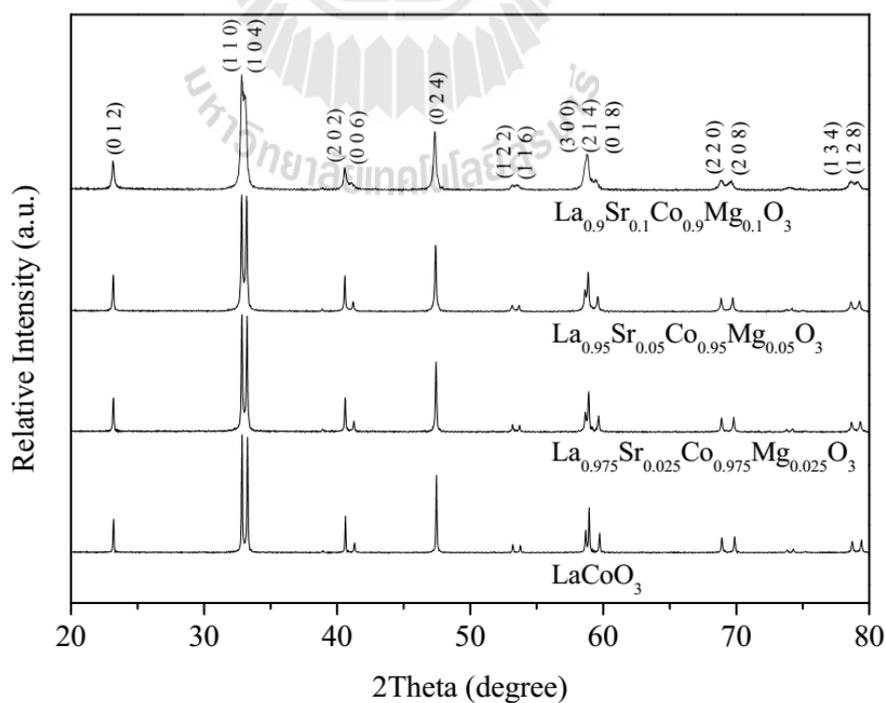

Figure 4.5 XRD patterns of $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0.025, 0.05, 0.1$).

Å) while A cation is smaller ($r_{A(\text{La})} = 1.032 \text{ Å}$); therefore, t is less than 1. The smaller size of La causes CoO_6 octahedra to tilt, and thus the structure is distorted from a cubic to a rhombohedral distorted-perovskite structure. The double substitution of Sr and Mg, which have greater ionic radii, for La and Co should cause an increase in the t value which leads to a higher symmetry in the crystal structure (Johnsson and Lemmens, 2007). In fact, it has been reported that $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$ show a structure transformation from a rhombohedral (when $x = 0-0.5$) to a cubic structure (when $0.55 < x < 0.7$) (Mineshige *et al.*, 1996). In our experiments, a change of symmetry with increasing x is also evident in the XRD patterns as two reflections near 33° are merging into one peak (Øy garden *et al.*, 2012).

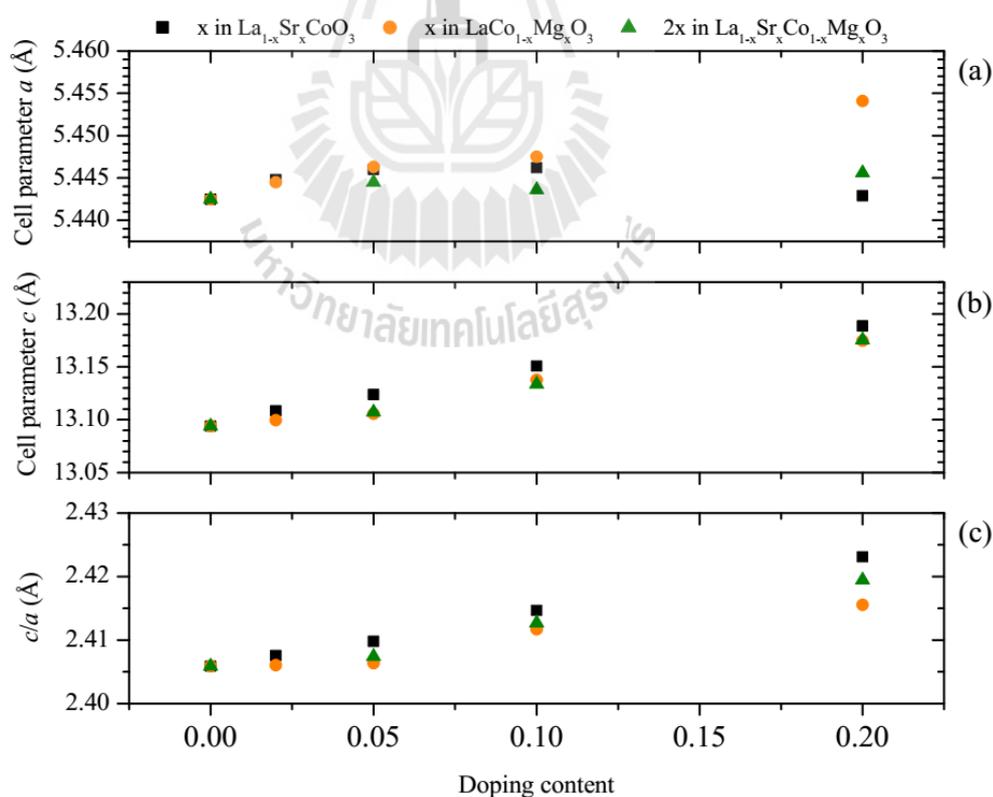

Figure 4.6 Cell parameters (a) a and (b) c and (c) the c/a ratio of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$, $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$, and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$.

4.2.4 Field Emission Scanning Electron Microscopy (FESEM)/Energy Dispersive X-ray Spectroscopy (EDS)

Morphology of the sintered samples was studied by FESEM technique. FESEM micrographs of all samples (Figure 4.7-4.18) show that particle sizes of the samples varying from 100 nm to 1 micron. The samples are homogeneous with a good particle distribution. The figures show spherical and/or random shape of particles which is resulted from the three dimensional structure of LaCoO₃-based compound. Compounds with layer structure often gives plate-like or sheet-like particle as the particles grow with certain plane preference. The images also indicate that the pellets have quite low density (about 80% of theoretical density).

4.3 Thermoelectric properties

4.3.1 Electrical resistivity

The evolution of electrical resistivity of the samples at room temperature with doping is shown in Figure 4.19. Both single and double substitutions of Sr and Mg decrease the electrical resistivity of LaCoO₃. The replacement of La³⁺ by Sr²⁺ and Co³⁺ by Mg²⁺ are compensated either by the oxidation of Co³⁺ to Co⁴⁺ which creates

holes, or by the introduction of oxygen vacancies (Mineshige *et al.*, 1999). In general, a higher level of dopant results in lower electrical resistivity because of the higher carrier concentration as $1/\rho = ne\mu$ when n is carrier concentration, e is electric charge, and μ is carrier mobility (Snyder and Toberer, 2008). However, μ is also affected by the substitutions. Generally, Co^{4+} generated by substitutions of lower heterovalent cations enhances the Co-O bonding, and thus broadens the bandwidth to improve electron conduction (Ramadass *et al.*, 1979). Therefore, substitution of Sr and Mg should result in decreased resistivity as both n and μ are increased. However, in the case of Mg substitution, the decrease of electrical resistivity is limited and the value increases when Mg content exceeds 10%. This can be explained when the electron transfer of the LaCoO_3 perovskite which occurs in the Co-O network of CoO_6 octahedra is taken into account. As substituted Mg locates in the said network, it may

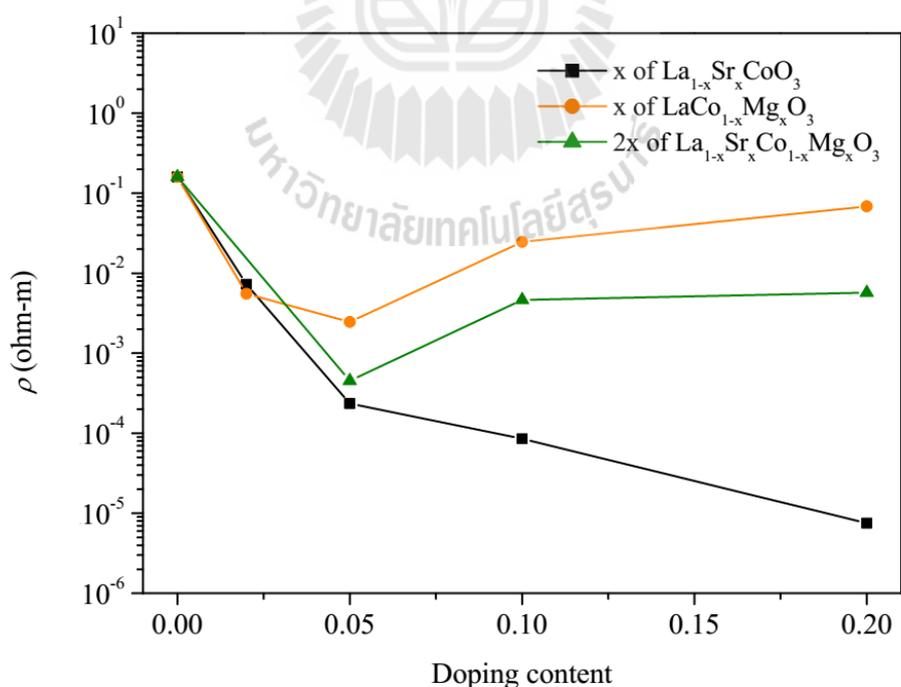

Figure 4.19 Evolution of the room-temperature electrical resistivity as a function of doping content.

block this pathway and results in decreased μ . This explanation is reasonable since there are only localized electrons in Mg^{2+} . The observed decrease of resistivity in the Mg-substituted samples is, therefore, a result of the competing mechanisms; an increase of n , an increase of μ through Co^{4+} formation, and a decrease of μ through blockage of Co-O network. In the case of Sr doping, Sr locates at the La site and does not disrupt Co-O network. Hence it should not directly affect carrier mobility in the same manner. In fact, a detailed study on Sr-substituted LaCoO_3 has shown that the Sr substitution increases n and μ , both of which contribute to reduce electrical resistivity (Iwasaki *et al.*, 2008). The resistivity of the double-substituted samples is in between those of the Sr- doped and Mg- doped samples.

4.3.2 Seebeck coefficient

The Seebeck coefficients (S) of all samples are shown as Figure 4.20. All substituted- LaCoO_3 samples show positive S indicating that the main charge carriers

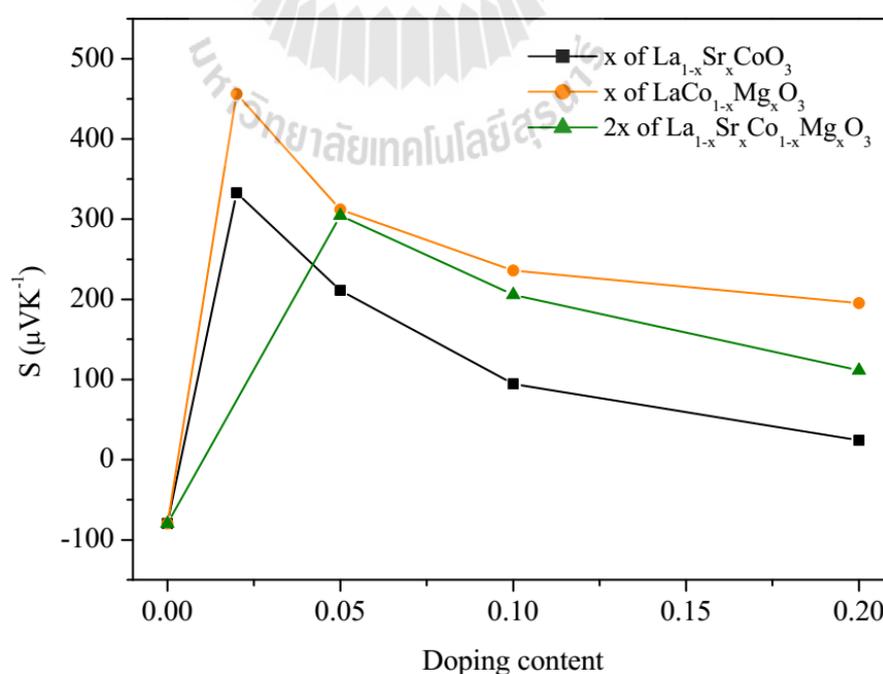

Figure 4.20 Plot of Seebeck coefficients as a function of doping content.

are holes. However, it is interesting to note that S is negative in the case of LaCoO_3 . This effect is also reported in some other works (Iwasaki *et al.*, 2008; Sehlin *et al.*, 1995; Ohtani *et al.*, 2000). The sign of S can be varied from negative to positive and an oxygen vacancy is assumed to be the reason (Vulchev *et al.*, 2012; Berggold *et al.*, 2005). The Mg substitution effectively enhances the Seebeck coefficient. The values of $\text{LaCo}_{1-y}\text{Mg}_y\text{O}_3$ with $x = 0.05$ and 0.1 prepared in this work are 312 and $236 \mu\text{VK}^{-1}$, respectively, which are higher than 190 and $230 \mu\text{VK}^{-1}$ of those prepared by Ramadass *et al.* (1979). Nonetheless, the S of the $x = 0.05$ sample is lower than $400 \mu\text{VK}^{-1}$ reported by Hejtmánek *et al.* (2008).

When the samples with same doping content are compared, Mg doping has significantly larger effects in improving S than Sr doping and the Seebeck coefficients of co-doped samples are in between those of singly doped ones. Koshibe *et al.* (2000) proposed that the characteristic spin degeneracy and strong correlation of $3d$ electrons in cobalt oxides cause the large Seebeck coefficient. In the case of cobalt oxides, the Heikes formula has been used to describe the Seebeck effect; $S = -k_B/e[\ln(g_3/g_4)(x/1-x)]$ where g_3 and g_4 are the numbers of spin states for Co^{3+} and Co^{4+} , respectively, and x is the concentration of Co^{4+} . Hund's rule coupling, crystal field splitting energy ($10Dq$), and temperature are parameters that determine g_3 and g_4 . The ratios of g_3/g_4 and $x/1-x$ influence not only the magnitude but also the sign of S (Koshibae *et al.*, 2000). In this work, the increase in the doping content leads to the decrease of the Seebeck coefficient for all cation-substituted series, which can be explained by this equation. Although the p-type substitution of LaCoO_3 plays an important role in decreasing electrical resistivity, it is always accompanied by the reduction of Seebeck coefficient which indicates that these two parameters are strongly correlated (Ohtaki

et al., 2011). Substitutions with other cations, i.e., Sr (Iwasaki *et al.*, 2008; Mandal *et al.*, 2005; Zhou *et al.*, 2006; Zhou *et al.*, 2008a; Zhou *et al.*, 2008b), Ba (Mandal *et al.*, 2004; Hejtmánek *et al.*, 2004), Ca (Weidenkaff *et al.*, 2008), and Ni (Kozula *et al.*, 2012; Robert *et al.*, 2006; Robert *et al.*, 2007; Vulchev *et al.*, 2012; Li and Li, 2011; Robert *et al.*, 2008), also increase electrical conductivity and decrease Seebeck coefficient. In contrast, the Mg substitution seems to have less effect in decreasing Seebeck coefficient.

4.3.3 Thermal conductivity

Thermal conductivity is plotted with doping content as shown in Figure 4.21. Total thermal conductivity (κ_T) consists of the electronic part (κ_E) and the lattice part (κ_L). Electronic thermal conductivity, which is related to electrical resistivity

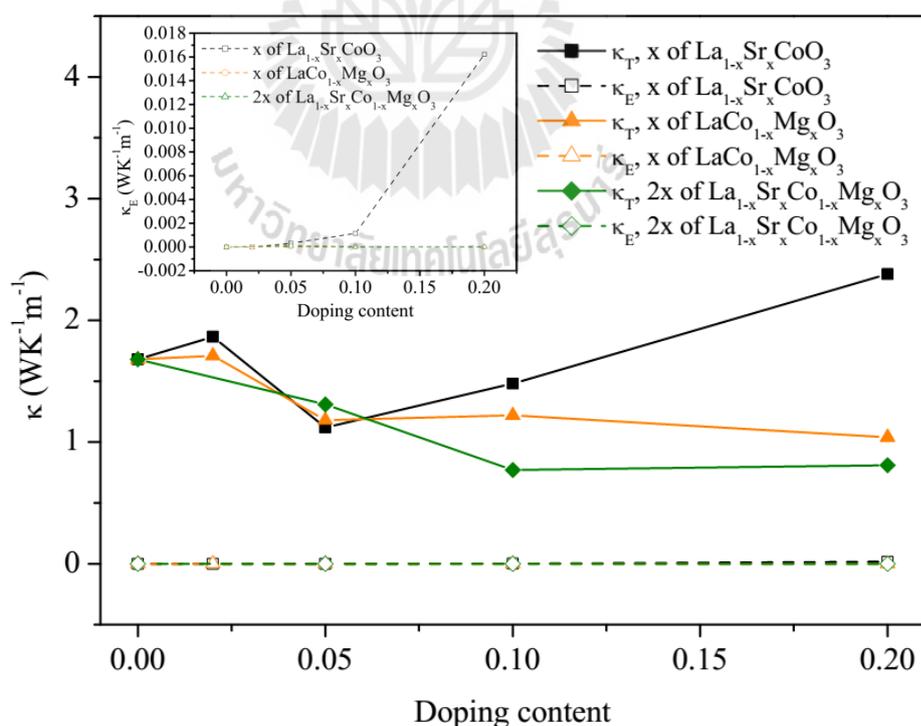

Figure 4.21 Plot of total thermal conductivity (solid line) and electronic thermal conductivity (dash line and inset) as a function of doping content.

through the Wiedemann–Franz law, ($\kappa_E = 1/\rho(LT)$, where L is the Lorenze factor), is plotted by the dash line. Lattice thermal conductivity can be calculated by subtracting the electronic part from total thermal conductivity. It is clearly seen that, in all cases, lattice thermal conductivity has more contribution to total thermal conductivity. In general, cation substitutions that create disorder in the solid structure suppress heat transfer so that the thermal conductivity is reduced. In our experiments, doping with Mg is more effective on reducing thermal conductivity than with Sr. Moreover, the decrease of thermal conductivity is more pronounced with the double substitutions, which is because they introduce more cation disordering. Note that the thermal conductivity of almost all samples are less than $2 \text{ WK}^{-1}\text{m}^{-1}$ which is considered to be the minimum value for good thermoelectric properties (Tritt and Subramanian, 2006).

4.3.4 The figure of merit ZT

Power factors, $(1/\rho)S^2$, of all samples are shown in Figure 4.22. The highest value of $0.02048 \text{ WK}^{-2}\text{m}^{-1}$ is achieved in $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.0975}\text{Mg}_{0.025}\text{O}_3$. In this sample, the Sr substitution plays an important role in increasing electrical conductivity, while the Mg substitution helps in maintaining the high Seebeck coefficient. However, when the thermal conductivity is taken into account, $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.0975}\text{Mg}_{0.025}\text{O}_3$ has a slightly lower ZT compared with that of $\text{La}_{0.95}\text{Sr}_{0.05}\text{CoO}_3$ owing to the higher thermal conductivity (Figure 4.23). $\text{La}_{0.95}\text{Sr}_{0.05}\text{CoO}_3$ prepared in this work gives a ZT of 0.052 which is slightly higher than 0.033 reported by Zhang *et al.* (2006). When the three key parameters are compared between them, our sample has less electrical resistivity, lower Seebeck coefficient and similar thermal conductivity, which result in the better ZT. In addition, a ZT of 0.021 for $\text{La}_{0.9}\text{Sr}_{0.1}\text{CoO}_3$ in this work is rather different from 0.046 reported

by Zhou *et al.* (2008a). The reason behind these differences is unclear.

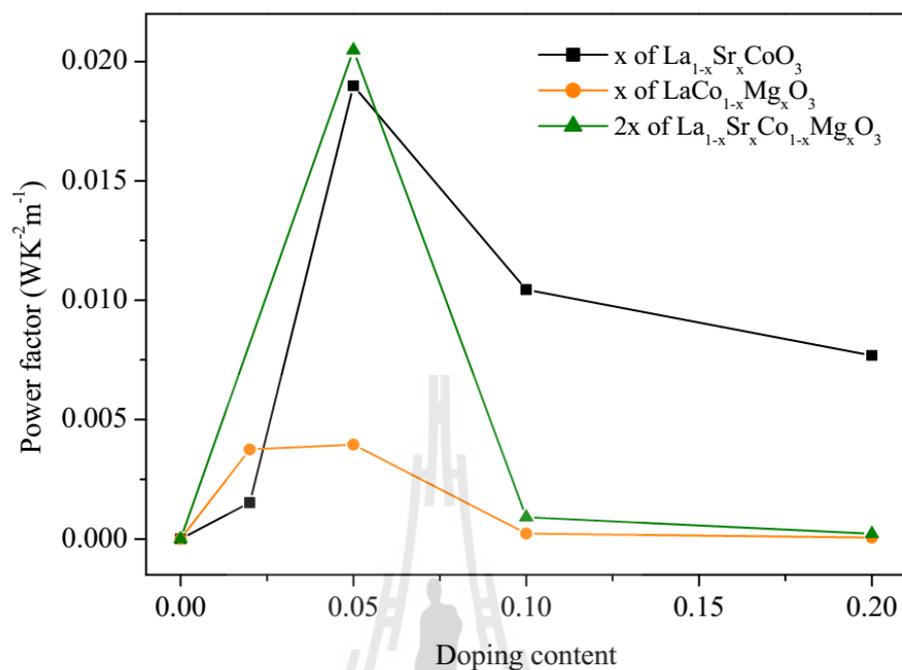

Figure 4.22 Plot of power factors as a function of doping content.

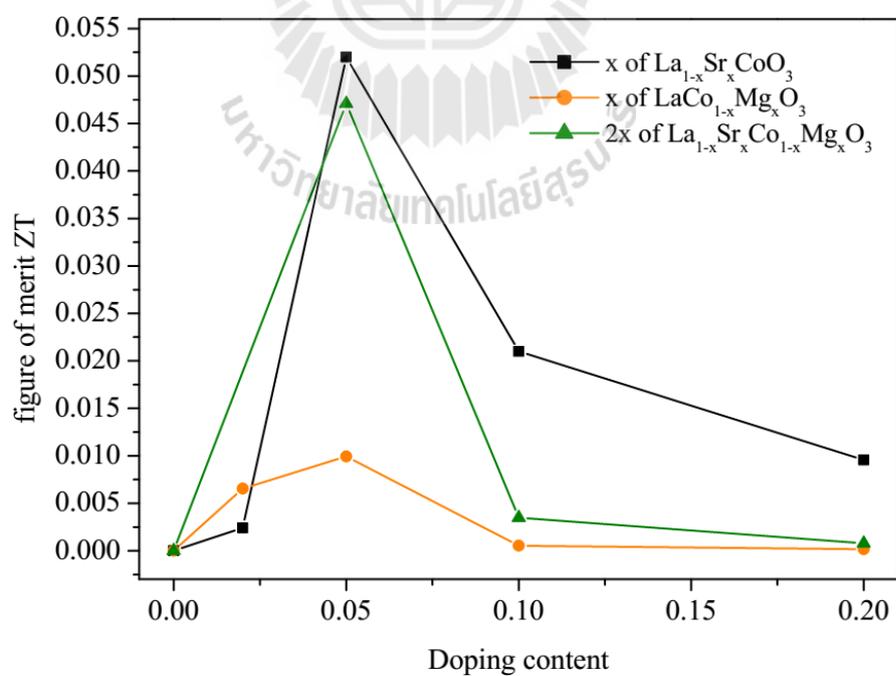

Figure 4.23 Plot of figure of merit ZT as a function of doping content at room temperature.

Some factors such as grain size, porosity, or grain boundary might have some effects and should be considered (Zhang *et al.*, 2006). The density of all samples prepared in this work is approximately 80% of the theoretical density.

Although ZT values obtained here are still quite low compared with some other values reported on LaCoO₃ related samples such as 0.16 for LaCo_{0.98}Ni_{0.01}Fe_{0.01}O₃ (Vulchev *et al.*, 2012), it is shown that co-substitutions in different sites can be a promising way to improve thermoelectric properties for a further development in related materials.

CHAPTER V

CONCLUSION

Three series of polycrystalline samples of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$, $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.02, 0.05, 0.1, 0.2$), and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.025, 0.05, 0.1$) have been successfully prepared without impurity phases by the citrate sol-gel method. The cations compositions were confirmed by EDS. Increasing the amount of dopants, Sr and Mg, causes expansions in cell parameters a and c , because bigger Sr and Mg atoms are substituted for La and Co atoms, respectively. Thermoelectric properties of all series have been examined in terms of electrical resistivity (ρ), Seebeck coefficient (S), and thermal conductivity (κ) measurements. Compared with LaCoO_3 , resistivity is decreased after replacing La by Sr, but not by as much in the case of Mg doping because Mg may block the electron transfer pathway in the CoO_6 network. On the other hand, Mg substitution has more effect in maintaining a high Seebeck coefficient. The double substitution of Sr and Mg improves the thermoelectric properties as evidenced by the increase in the power factor. In addition, the double substitution also decreases the lattice part of thermal conductivity, which further improves their thermoelectric efficiency. Among all the double-substituted samples studied in this work, $\text{La}_{0.975}\text{Sr}_{0.025}\text{Co}_{0.975}\text{Mg}_{0.025}\text{O}_3$ gives the best ZT of 0.047 at room temperature.

APPENDIX A

CALCULATION: A SAMPLE PREPARATION AND A SAMPLE DENSITY

A.1 Calculation of a sample preparation

Samples of $\text{La}_{1-x}\text{Sr}_x\text{CoO}_3$, $\text{LaCo}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.02, 0.05, 0.1, 0.2$), and $\text{La}_{1-x}\text{Sr}_x\text{Co}_{1-x}\text{Mg}_x\text{O}_3$ ($x = 0, 0.025, 0.05, 0.1$) were prepared by weighting starting materials in a stoichiometric ratio. The calculation procedure is as following;

Firstly, the number of mol of a sample is calculated using molecular weight (M.W.) of a sample.

$$\text{mol of a sample} = (\text{gram of a sample})/(\text{M.W. of a sample})$$

Secondly, a weight of each precursor is calculated using its M.W., mol of a sample (from the first step), and mol of an atom (in a formula).

$$\text{weight of a precursor} = (\text{M.W. of a precursor}) \times (\text{mol of a sample}) \times (\text{mol of an atom})$$

For example, 1 gram of $\text{La}_{0.9}\text{Sr}_{0.1}\text{Co}_{0.9}\text{Mg}_{0.1}\text{O}_3$ can be prepared by following calculations;

$$\begin{aligned} \text{mol of } \text{La}_{0.9}\text{Sr}_{0.1}\text{Co}_{0.9}\text{Mg}_{0.1}\text{O}_3 &= 1 \text{ g}/(237.25 \text{ g/mol}) \\ &= 0.004214963119 \text{ mol} \end{aligned}$$

$$\begin{aligned} \text{weight of } \text{La}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O} &= 433.01 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.9 \text{ mol} \\ &= 1.6426 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of Co(NO}_3)_2 \cdot 6\text{H}_2\text{O} &= 291.03 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.9 \text{ mol} \\ &= 1.1040 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of Sr(NO}_3)_2 &= 211.63 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.1 \text{ mol} \\ &= 0.0892 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of Mg(NO}_3)_2 \cdot 6\text{H}_2\text{O} &= 256.41 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.1 \text{ mol} \\ &= 0.1081 \text{ g} \end{aligned}$$

Regarding the ratio of cations: citric acid (1:4), mol of a citric acid can be calculated by multiplying mol of a sample, mol of an atom, and M.W. of a citric acid ($\text{C}_6\text{H}_8\text{O}_7 \cdot \text{H}_2\text{O}$) by 4.

$$\begin{aligned} \text{weight of a citric acid for La(NO}_3)_3 \cdot 6\text{H}_2\text{O} &= 210.14 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.9 \text{ mol} \\ &= 0.7972 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of a citric acid for Co(NO}_3)_2 \cdot 6\text{H}_2\text{O} &= 210.14 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.9 \text{ mol} \\ &= 0.7972 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of a citric acid for Sr(NO}_3)_2 &= 210.14 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.1 \text{ mol} \\ &= 0.0886 \text{ g} \end{aligned}$$

$$\begin{aligned} \text{weight of a citric acid for Mg(NO}_3)_2 \cdot 6\text{H}_2\text{O} &= 210.14 \text{ g/mol} \times 0.004214963119 \text{ mol} \times 0.1 \text{ mol} \\ &= 0.0886 \text{ g} \end{aligned}$$

A.2 Calculation of a sample density

In this work, a density of all samples is calculated generally as it is equal to mass divided by volume; density of a sample = mass/volume. A volume can be obtained depending on a sample's geometry. Percent of density is then reported comparing to their theoretical density. A theoretical density can be calculated from M.W. of a sample, cell volume (calculated from lattice parameters), a number of atoms per unit cell (Z), and Avogadro's number (6.023×10^{23} /mol).

$$\text{Theoretical density} = \frac{Z \times \text{M.W. of a sample}}{\text{cell volume} \times \text{Avogadro's number}}$$

For example, the density of LaCoO_3 is as

$$\begin{aligned} &= \text{mass/volume} \\ &= 0.1380 \text{ g}/0.02366 \text{ cm}^3 \\ &= 5.8319 \text{ g/cm}^3 \end{aligned}$$

The theoretical density of LaCoO_3 is as

$$\begin{aligned} &= \frac{Z \times \text{M.W. of a sample}}{\text{cell volume} \times \text{Avogadro's number}} \\ &= \frac{6 \times 245.84 \text{ g.mol}^{-1}}{387.85 \text{ cm}^3 \times 6.023 \times 10^{23} \text{ mol}^{-1}} \\ &= 6.3142 \text{ g/cm}^3 \end{aligned}$$

So, the sample density percentage of LaCoO_3 is as

$$\begin{aligned} &= \frac{\text{a sample density}}{\text{a theoretical density}} \times 100 \\ &= \frac{5.8319 \text{ g.cm}^3}{6.3142 \text{ g.cm}^3} \times 100 \\ &= 92.36\% \end{aligned}$$
