THERMAL STABILITY / POLYMER HOSTS / NANOCONFINEMENT /
HYDRIDE-POLYMER INTERACTION / LITHIUMBOROHYDRIDE /
SODIUMALUMINIUMHYDRIDE

NaAlH_4 doped into nanoconfined LiBH_4 in poly (methyl methacrylate)-co-butyl methacrylate (PcB), denoted as nano LiBH_4 - NaAlH_4 -PcB, is proposed for reversible hydrogen storage. The reduction of LiBH_4 /PcB interaction ($\text{B} \cdots \text{OCH}_3$) and improvement of thermal stability of PcB are expected to obtain by adding small amount of NaAlH_4 . The LiBH_4 /PcB interaction of the nanoconfined samples is analyzed quantitatively by using FTIR technique, where the $\nu(\text{B-H})/\nu(\text{C=O})$ ratio directly related to the amount of $[\text{BH}_4]^-$ is determined. The more the $(\nu(\text{B-H})/\nu(\text{C=O}))$ ratio, the higher the free $[\text{BH}_4]^-$ content and the lower the LiBH_4 /PcB interaction. The $(\nu(\text{B-H})/\nu(\text{C=O}))$ ratio of the nano LiBH_4 -PcB and nano LiBH_4 - NaAlH_4 -PcB are 0.6 and 2.8, respectively. This refers to the reduction of LiBH_4 /PcB interaction due to addition of NaAlH_4 . This is in agreement with B 1s XPS results, the relative amount of B_xO_y (from LiBH_4 /PcB interaction) with respect to LiBH_4 of nano LiBH_4 - NaAlH_4 -PcB is lower than that of nano LiBH_4 -PcB. In addition, the solid state MAS NMR and XRD results of nano LiBH_4 - NaAlH_4 -PcB confirms that the LiBH_4 /PcB

interaction is decreased due to the competitive reaction of $[\text{AlH}_4]^-$ (of NaAlH_4) with $-\text{OCH}_3$ and/or $-\text{OC}_4\text{H}_9$ (of PcB). These results increase of H_2 content dehydrogenated during cycling. Moreover, the interaction between alkoxy groups ($-\text{OCH}_3$ and/or $-\text{OC}_4\text{H}_9$) of PcB and metal hydrides (LiBH_4 and NaAlH_4) as well as that between carbonyl group (from PcB) and metal ions (Li^+ and Na^+) result in the improvement of thermal stability of PcB.

ACKNOWLEDGEMENTS

I would like to thank everyone, who has helped me throughout my studies. I am immensely grateful to my advisor, Asst. Prof. Dr. Rapee Gosalawit-Utke for the patience and hard lessons, making me an independent and critical mind. I am also thankful to the thesis examining committee, including Asst. Prof. Dr. Sanchai Prayoonpokarach, Asst. Prof. Dr. Kunwadee Rangriwatananon, and Dr. Theeranun Siritanon for their helpful and suggestions during my thesis defense.

I would like to acknowledge Mrs. Yanling Hua (The center for Scientific and Technological Equipment, Suranaree University of Technology, Thailand) for technical help and suggestions for solid-state MAS NMR measurements, Dr. Hideki Nakajima (BL3.2a: PES, Synchrotron Light Research Institute, Thailand) for technical help and suggestions for XPS measurements, Mr. Danial Laipple (Institute of Materials Research, Helmholtz-Zentrum Geesthacht, Geesthacht 21502, Germany) for technical help of SEM-EDS-mapping, and Dr. Chiara Minalese (Pavia Hydrogen Lab., C. S. G.I., Department of Chemistry, Physical Chemistry Division, University of Pavia, Pavia 27100, Italy) for technical help of gas analysis.

Personal thanks and love to my family, who has supported me. I am also grateful to all friends in the research group for sharing with me good and bad time.

CHAPTER I

INTRODUCTION

1.1 Renewable energy technology

Energy sources

Energy can be obtained from different sources, such as chemical (fossil fuels), solar (photovoltaic cell), nuclear (uranium) and thermo mechanical (wind, water and hot water) energy. Each kind of energy has its own problems. For example, the use of fossil fuels leads to the production of the greenhouse gas (CO₂). This causes global warming and climate change (Environmental and Energy Study Institute, www, 2014). For the nuclear energy, the problem is nuclear wastes (Problems and Dangers of Nuclear Energy, www, 2014), while solar and wind energy require the use of large areas (Michael, 2014).

Currently, fossil fuel and nuclear sources are the main energy suppliers for the world. The high consumption of fossil fuel is expected to enhance the greenhouse gas (CO₂) in the atmosphere and to deplete fossil fuel supplies in the coming decades. The continuous emission of CO₂, which leads to world warming, is a serious problem for the global environment. Also, in the coming century, the world population is supposed to be increased together with a rapid growth of the economies. Thus, this will result in a higher demand of the energy consumption of the world. In order to meet the growth of energy requirement, while producing less CO₂, the current energy

of fossil fuels has to be replaced by new environmental friendly sources, such as solar, geothermal, wind, and hydrogen energy (Energy Resources, www, 2014).

1.2 Hydrogen energy

Hydrogen is one of the most promising energy carriers, which can potentially replace fossil fuels as sources of clean energy due to high energy density of 142 MJ kg^{-1} (Jain *et al.*, 2010), light weight, great variety of potential sources (water, biomass, and organic matter), and low environmental impact (water and heat are by-product). Hydrogen energy is mainly used in fuel cells for various applications, such as electric power, transportation, industry, and public welfare. Good example is hydrogen car (Figure 1.1), planned to be worldwide sold by Honda and Toyota in 2015.

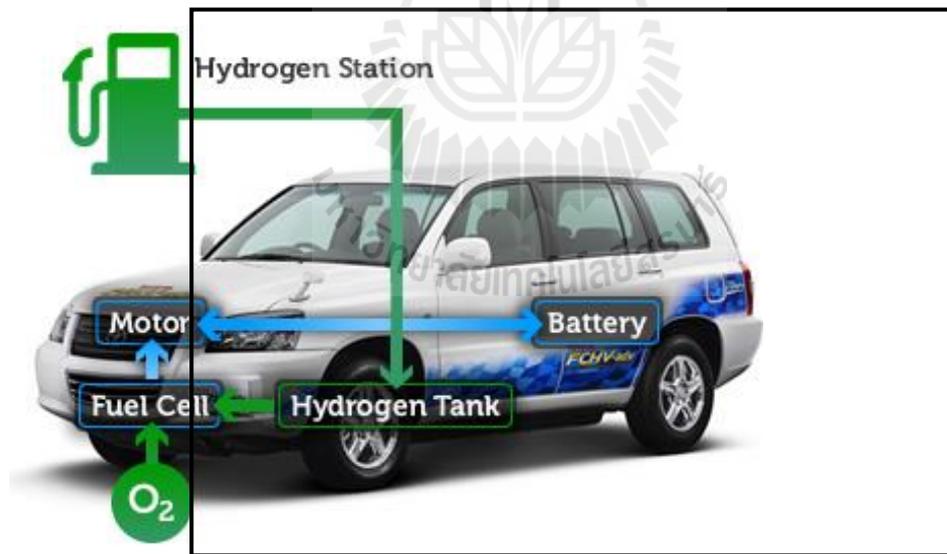

Figure 1.1 Components of fuel cell car (<http://www.engineering.com/DesignerEdge/DesignerEdgeArticles/ArticleID/5974/Hydrogen-Powered-Cars-Coming-to-a-highway-near-you.aspx>).

Fuel cell car includes four major components of:

1. fuel cell stack: the fuel cell is an electrochemical device that produces electricity using hydrogen and oxygen. To obtain enough electricity to power a vehicle, individual fuel cells are combined in series to make a fuel cell stack,
2. hydrogen tank: instead of a gasoline or diesel tank, a fuel cell car has a hydrogen storage tank. The hydrogen gas must be compressed at extremely high pressure of 5,000 to 10,000 pounds per square inch (psi) to store enough fuel to obtain adequate driving range (Natural Gas Vehicles for America, www, 2011),
3. motor: it governs flow of electricity in the vehicle. By drawing power from either the battery or the fuel cell stack, it delivers electric power to the motor, which then uses the electricity to drive the vehicle (U.S. DOE, Office of EERE, Alternative & Advanced Vehicles, www, 2010), and
4. battery: fuel cell car has a battery that stores electricity generated, which increase the overall efficiency of the vehicle (U.S. DOE, Office of EERE, Alternative & Advanced Vehicles, www, 2010).

1.3 Fuel cells

A fuel cell is a device that generates electricity by an electrochemical reaction. A single fuel cell has two electrodes (anode and cathode), an electrolyte, and a catalyst. In practice, many fuel cells are usually assembled into a stack for more electricity production. There are several different types of fuel cells, typically grouped according to their operating temperatures and types of electrolytes used (Table 1.1). The amount of power generated by a fuel cell is determined by several factors

including fuel cell types, size, operating temperatures, and pressure. The most common type of fuel cell used in fuel cell car is proton exchange membrane fuel cell (PEMFC).

Table 1.1 Comparisons of fuel cell technologies applications (Carrette *et al.*, 2001).

Fuel cell types	Electrolytes	Operating temperatures (°C)	Applications
Proton exchange membrane fuel cell (PEMFC)	Polymer	50-100	- Backup power - Portable power - Transportation
Alkaline fuel cell (AFC)	KOH	90-100	- Military, Space
Phosphoric acid fuel cell (PAFC)	H ₃ PO ₄	150-200	- Distributed generation
Solid oxide fuel cell (SOFC)	ZrO ₂	700-1000	- Auxiliary power - Electric utility - Distributed generation

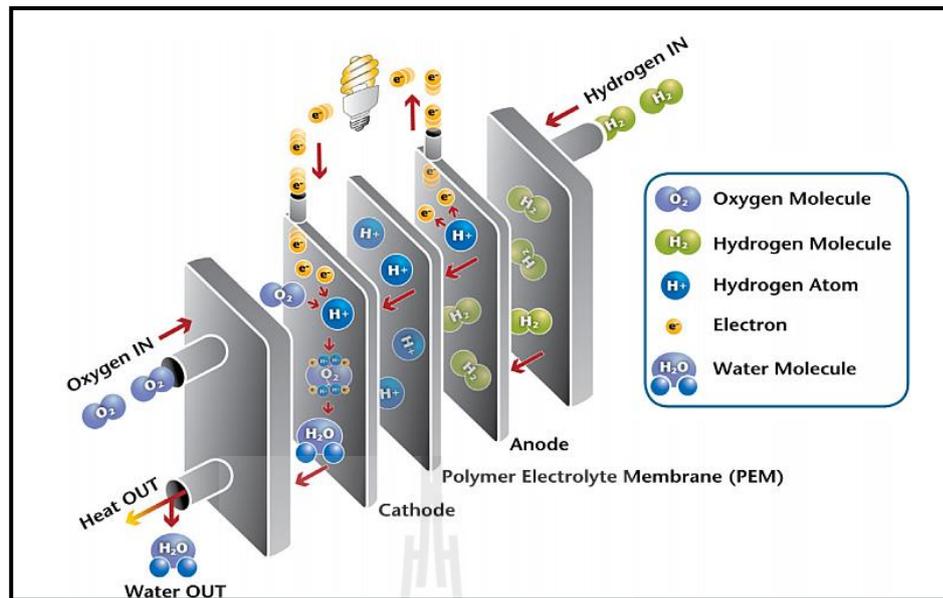

Figure 1.2 PEMFC single cell (<http://energydesignresources.com/resources/e-news/e-news-90-fuel-cells.aspx>).

Considering reaction mechanisms of PEMFC, the anode interacts with the provided fuel source hydrogen gas to generate protons and electrons. The protons travel through the electrolyte membrane to the cathode, while the electrons, which cannot pass through the electrolyte, create the electric current before being returned to cathode. The cathode then catalyzes oxygen with protons and returned electrons, and this combination produces water and heat as products. The reaction mechanisms of PEMFC are shown in the following equations.

PEMFC is a type of low temperature fuel cell with an operating temperature in the range of 50-100 °C. Moreover, it has high current density and power density. When compared to other fuel cells, PEMFC has compact design, light weight, and faster response time. For practical uses in fuel cell car, many single PEMFCs are usually combined as a fuel cell stack. Furthermore, to use PEMFC stack efficiently, effective on-board hydrogen storages with high capacity (both gravimetric and volumetric storage) as well as operating at moderate temperature conditions are extremely required.

1.4 Hydrogen storage methods

In principle, hydrogen can be stored in many forms, mainly as compressed hydrogen gas, liquid hydrogen, and solid state hydrides (Table 1.2).

Table 1.2 Comparison of three major competing technologies for hydrogen storages (Varin *et al.*, 2009).

Storage systems	Volumetric hydrogen capacity (kgH ₂ m ⁻³)	Drawbacks
Compressed hydrogen gas under 80 MPa pressure	~40	<ul style="list-style-type: none"> - safety problem - cost of pressurization - large pressure drop during use
Liquid hydrogen at cryogenic tank at -252 °C (21 K)	~71	<ul style="list-style-type: none"> - large thermal losses (open system) - safety problem - cost of liquefaction
Solid state hydrides	80-160	<ul style="list-style-type: none"> - none of the above

1.4.1 Compressed hydrogen gas

For this system, hydrogen is normally compressed and stored in gas cylinders, which are the simplest and cheapest method for on-board vehicles. However, its main obstacle is low storage density. In addition, high storage pressures raise the cost of the system as well as safety issues (Sandi, 2004).

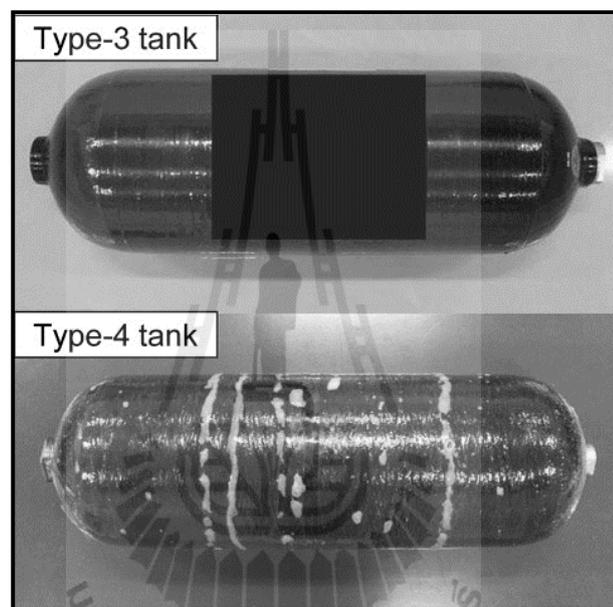

Figure 1.3 Compressed hydrogen gas tank (Tomioka *et al.*, 2011).

1.4.2 Liquid hydrogen

Liquid hydrogen is an alternative storage to compressed hydrogen, where hydrogen can be liquefied under critical low temperature ($-252\text{ }^{\circ}\text{C}$). Liquefaction takes place through a number of steps, in which the hydrogen is compressed and cooled to form a dense liquid. A major drawback of liquefied hydrogen storage is high cost of liquefaction processes and huge amount of electricity consumption (Züttel, 2004).

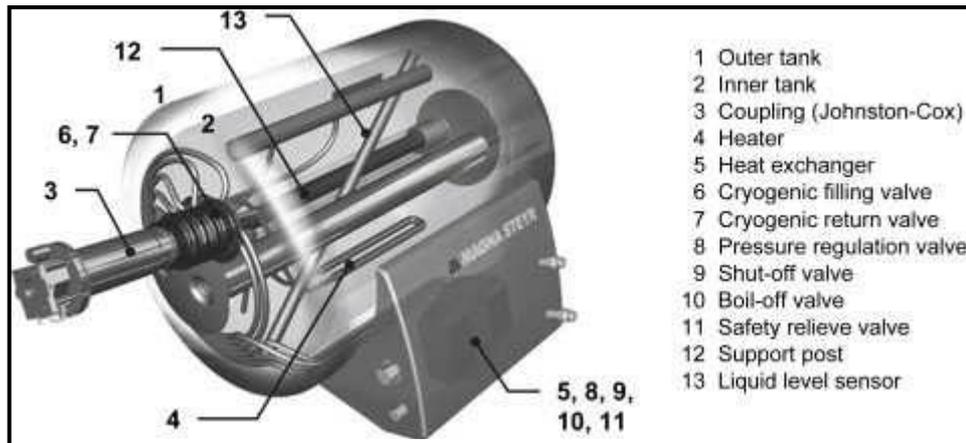

Figure 1.4 Liquid hydrogen tank (Mori *et al.*, 2009).

1.4.3 Solid state hydrides

In solid state hydrides, hydrogen can be stored by combining hydrogen with solid state materials through chemical reactions. Many metals are able to be combined chemically with hydrogen to form a class of compounds called metal hydrides. Metal hydrides have the highest volumetric hydrogen density and operate without drawbacks as in compressed and liquid hydrogen systems. Moreover, the storage tank is compact with respect to those of compressed and liquid hydrogen (Basic Research Challenges for Hydrogen Storage, 2004).

Figure 1.5 Solid state hydrogen storage tank (<http://www.flyhy.eu/HZG.html>).

Therefore, several research groups have focused on solid state hydrides for hydrogen storage applications. However, there are still a lot of obstacles needed to be solved, especially high temperature of hydrogen sorption and slow kinetics. The targets for hydrogen storage materials mentioned by Department of Energy (US DOE) in 2015 are reviewed by Varin *et al.* (2009) and shown in Table 1.3.

Table 1.3 US DOE Freedom CAR hydrogen storage system targets (Varin *et al.*, 2009).

Targets	2015
Specific energy (MJ kg ⁻¹)	10.8
Gravimetric capacity (wt.%)	9
Volumetric capacity (kgH ₂ m ⁻³)	81
Storage system cost (\$ per kgH ₂)	67
Operating temperature (°C)	-40/60
Cycle life-time (absorption/desorption cycles)	1,500

CHAPTER II

LITERATURE REVIEWS

Among all hydrogen storage materials, solid state hydrides have the highest hydrogen volumetric and gravimetric densities, and they do not need excessively high pressure and low temperature as required for compressed gas and liquid hydrogen. Moreover, the solid state hydrides have been proposed to be one of the most suitable on-board H₂ storages in transportation applications powered by PEMFC stack due to its high volumetric hydrogen capacity of 80-160 kgH₂ m⁻³, compact size, light weight, and high purity of H₂ output (Varin *et al.*, 2009; Schlapbach and Züttel, 2001; Ritter *et al.*, 2003; Züttel *et al.*, 2003; Fichtner *et al.*, 2005). These solid state H₂ storage materials are reported in several forms, e.g., metal hydrides (MgH₂ and AlH₃) (Bogdanovic and Schwickardi, 1997), complex hydrides (LiAlH₄, Mg(AlH₄)₂, NaAlH₄, Na₃AlH₆, Na₂LiAlH₆) (Sun *et al.*, 2003; Fu *et al.*, 2006), and composite hydrides (LiBH₄-NaAlH₄) (Gross *et al.*, 2008; Ronggeata *et al.*, 2010).

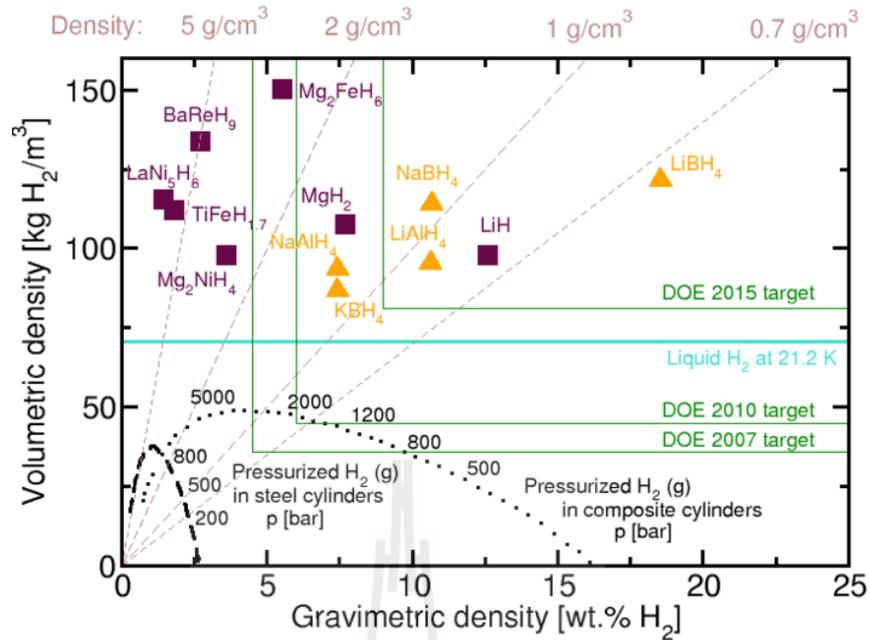

Figure 2.1 Volumetric and gravimetric hydrogen storage densities of different hydrogen storages (Grochala and Edwards, 2004).

From Figure 2.1, metal hydrides are represented by squares and complex hydrides triangles. Among them, lithium borohydride (LiBH_4) is one of the most outstanding complex hydrides because of its high volumetric and gravimetric hydrogen storage capacities (Züttel *et al.*, 2003). Unfortunately, its practical application in mobile fuel cell systems is limited due to both thermodynamic and kinetic drawbacks. It was found that after melting at about $280\text{ }^\circ\text{C}$, LiBH_4 started to dehydrogenate slowly (above $400\text{ }^\circ\text{C}$) to form LiH , B , and H_2 as shown in the following equation.

For rehydrogenation, it remains difficult due to the inactive elemental boron, resulting in very high operating temperature (above 600 °C) and pressure (350 bar H₂) required (Aoki *et al.*, 2005).

Moreover, sodium aluminium hydride (NaAlH₄), which has gravimetric and volumetric hydrogen storage capacities of 7.6 wt.% H₂ and 94 kgH₂ m⁻³, respectively, is regarded as one of the most promising compounds for H₂ storage material (Bogdanovic and Schwichardi, 1997). The dehydrogenation and hydrogenation of NaAlH₄ occur according to the following equations:

In theory, the first and the second steps released 3.7 and 1.9 wt.% H₂ at temperature of 274 and 299 °C, respectively (equations (5) and (6)). The last step released 1.9 wt.% H₂, which occurred in the temperature range of 425-500 °C (equation (7)). For the last step, the decomposition of NaH required high temperature is not useful for PEMFC. Therefore, the practical H₂ capacity is only 5.7 wt.%. Moreover, the reversibility was achieved only under high temperature (150 °C) and pressure (100 bar H₂) conditions (Bogdanovic *et al.*, 2006). From the disadvantages of LiBH₄ and NaAlH₄, there are various methods including catalytic doping, composite hydrides, and nanoconfinement in nanoporous scaffolds, proposed to decrease dehydrogenation temperature and to increase reversible reaction kinetics of LiBH₄ and NaAlH₄.

2.1 Catalytic doping

Yang *et al.* (2007) reported the destabilization of LiBH_4 by doping with metals (Mg, Al, Ti, V, Cr, or Sc) or metal hydrides (MgH_2 , TiH_2 , or CaH_2). They found that all LiBH_4 composites with metals and metal hydrides showed lower desorption temperature than pure LiBH_4 and LiBH_4 mixed with MgH_2 presented the lowest desorption temperature. Xia *et al.* (2009) enhanced the hydrogen storage properties of LiBH_4 by ball milling with various ratios of Ni powder, i.e., 2:1, 4:1 and 6:1 (LiBH_4 :Ni molar ratio) (Figure 2.2).

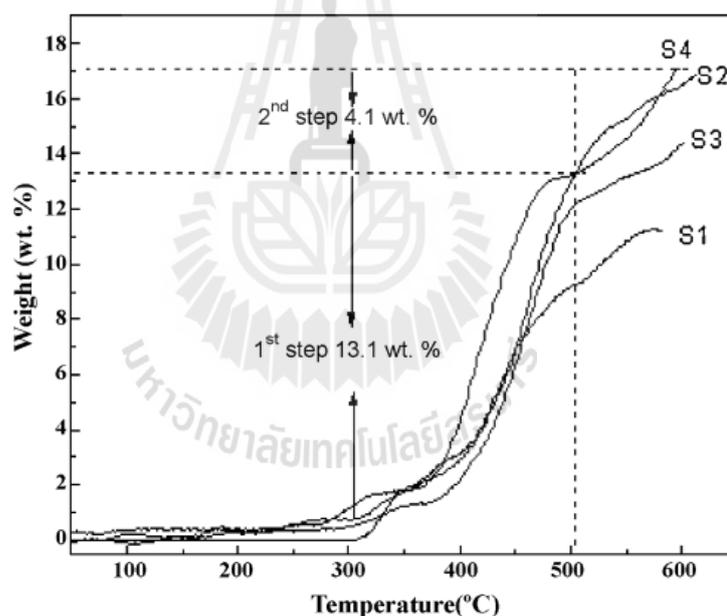

Figure 2.2 Hydrogen desorption curves of pure LiBH_4 (S1) and LiBH_4 -Ni with LiBH_4 :Ni molar ratios of 2:1 (S2), 4:1 (S3) and 6:1 (S4) (Xia *et al.*, 2009).

From Figure 2.2, the dehydrogenation of LiBH_4 and LiBH_4 -Ni samples starts at approximately 300 °C, suggesting that the addition of Ni did not reduce the dehydrogenation temperature of LiBH_4 . However, at about 600 °C, the weight loss

from S2, S3 and S4 samples are 17.2, 14.4 and 16.5 wt.% H₂, respectively, which are higher than that of pure LiBH₄ (11 wt.% H₂). Furthermore, the rehydrogenation of LiBH₄-Ni systems could be reversible partially at 600 °C under 100 bar H₂, where the operating condition is milder than pure LiBH₄ (600 °C, 350 bar H₂).

In the case of NaAlH₄, Bogdanovic *et al.* (2000) showed that the decomposition of NaAlH₄ could be kinetically enhanced and reversible with the addition of Ti-dopants. They found that addition of the Ti-dopants to NaAlH₄ enhanced the rate of reaction by decreasing the activation energy of the absorption and desorption cycles; however, the change in composition formation with the addition of Ti occurred in this material was still unknown. Sun *et al.* (2002) studied X-ray diffraction of NaAlH₄ doped with Ti-based dopants and they found that Ti³⁺ probably substituted Na⁺ of bulk NaAlH₄, resulting in induced distortions of the lattice.

2.2 Composite hydrides

A typical example for destabilization of LiBH₄ is the composite hydrides. Shi *et al.* (2008) investigated the hydrogen storage properties of LiBH₄-NaAlH₄ composite, both undoped and doped with a TiCl₃ additive. They found that milled 2LiBH₄-3NaAlH₄ doped with TiCl₃ gave a significant lower hydrogen release temperature as compared with undoped system. In the doped systems, the reaction between LiBH₄ and NaAlH₄ resulted in the formations of LiAlH₄ and NaBH₄. LiAlH₄ released hydrogen already at room temperature to form Li₃AlH₆, while NaBH₄ was destabilized by oxide-free Al at higher temperatures, which led to decrease of desorption temperature. In addition, the excess of NaAlH₄ could produce LiNa₂AlH₆ phase, which could be reversibly discharged and recharged hydrogen at 80 bar and 180 °C. In 2009, Blanchard *et al.* modified the reversibility of LiBH₄ by ball-milling

with LiAlH₄. LiAlH₄ could reduce the hydrogen desorption temperature of LiBH₄. For instance, the decomposition of LiBH₄+LiAlH₄ started at 100 °C and ended at 500 °C, which was lower than pure LiBH₄ (starting at 360 °C and ending at 500 °C). Later, Yu *et al.* (2009) investigated de/rehydrogenation mechanisms of LiBH₄ destabilized with metallic Al. They found that LiBH₄/Al mixture decomposed in two steps as the following reactions:

From reaction (8), AlB₂ was formed in the dehydrogenated state and disappeared in the hydrogenated state. The formation of AlB₂ decreased the stability of the materials, resulting in lower desorption temperature. Furthermore, rehydrogenation experiments revealed that an intermediate hydride was formed firstly at 600 °C and 30 bar H₂ pressure, and LiBH₄ could be reformed completely when H₂ pressure was increased to 100 bar. Zhang *et al.* (2009) improved the reversibility of LiBH₄ by synthesis of LiBH₄-MgH₂-Al (4:1:1 molar ratio) composite. They found that the onset dehydrogenation temperature of 4LiBH₄-MgH₂-Al was reduced by 173 °C as compared with those of 2LiBH₄-MgH₂ and 2LiBH₄-Al systems.

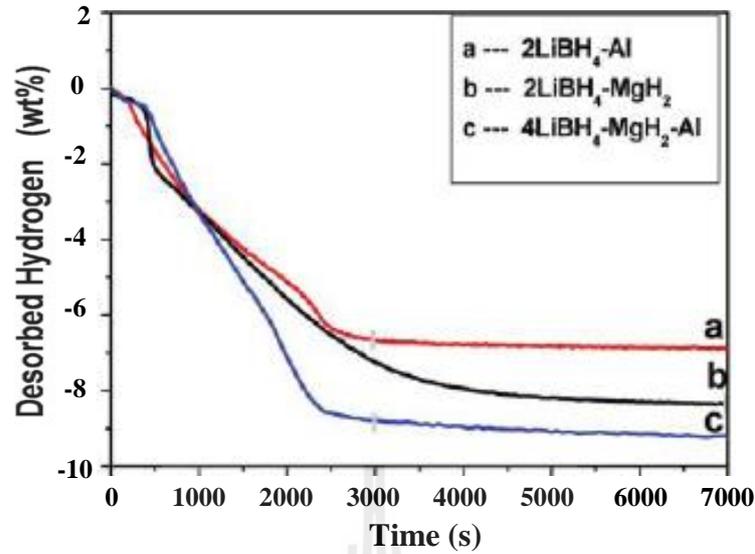

Figure 2.3 Isothermal dehydrogenation kinetics of $4\text{LiBH}_4\text{-MgH}_2\text{-Al}$, $2\text{LiBH}_4\text{-MgH}_2$, and $2\text{LiBH}_4\text{-Al}$ systems under a background pressure of 0.01 bar H_2 and at 400 °C. (Zhang *et al.*, 2009).

From Figure 2.3, at 3000 s, $4\text{LiBH}_4\text{-MgH}_2\text{-Al}$ system releases hydrogen of 9.4 wt.%, approaching to theoretical value (9.9 wt.% H_2), while those of the $2\text{LiBH}_4\text{-MgH}_2$ and $2\text{LiBH}_4\text{-Al}$ samples are 8 and 6.5 wt.% H_2 , respectively. The dehydrogenation reaction mechanism of $4\text{LiBH}_4\text{-MgH}_2\text{-Al}$ composite was proposed as shown in the following reaction:

As shown in reaction (10), the additions of MgH_2 and Al could effectively inhibit the formation of elemental boron during dehydrogenation (MgAlB_4 instead). For the rehydrogenation reaction of LiH-MgAlB_4 , it occurred in two steps as $4\text{LiH} + \text{MgAlB}_4 + 6\text{H}_2 \rightarrow \text{Mg} + 4\text{LiBH}_4 + \text{Al}$ and $\text{Mg} + \text{H}_2 \rightarrow \text{MgH}_2$. However, MgH_2 in the second step could not be fully recovered because partial Mg forming in the first step could alloy with Al to form Mg_2Al_3 . Next, Vajo *et al.* (2010) investigated thermodynamic

and kinetic destabilization of LiBH_4 by addition of Mg_2NiH_4 . They found that the equilibrium hydrogen pressure was higher than that of either pure LiBH_4 or pure Mg_2NiH_4 , and it approached to ideal value for hydrogen storage in PEMFC applications. Moreover, onset dehydrogenation temperature of $\text{LiBH}_4\text{-Mg}_2\text{NiH}_4$ composite was lower than those of LiBH_4 and Mg_2NiH_4 individually, illustrating a new pathway enabled by the mixture (reaction (11)).

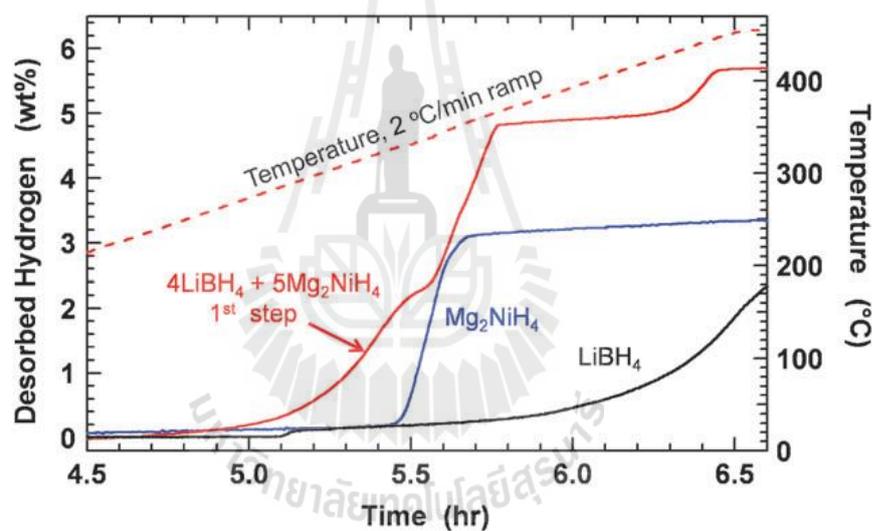

Figure 2.4 Dehydrogenation kinetics of $4\text{LiBH}_4\text{-}5\text{Mg}_2\text{NiH}_4$, Mg_2NiH_4 , and LiBH_4 (Vajo *et al.*, 2010).

From Figure 2.4, the dehydrogenation of $4\text{LiBH}_4\text{-}5\text{Mg}_2\text{NiH}_4$ occurs three steps at 250 °C, 340 °C, and 425 °C respectively. The amount of hydrogen desorbed in the 1st step is consistent with the reaction (11), which theoretically releases 2.6 wt.% H_2 . The 2nd step corresponds to dehydrogenation of MgH_2 produced during the reaction between LiBH_4 and Mg_2NiH_4 (reaction (11)) and the 3rd step is due to the decomposition of

excess LiBH_4 (Figure 2.4). Moreover, Dorthe *et al.* (2010) studied the hydrogen release of $\text{LiBH}_4\text{-NaAlH}_4$ composite.

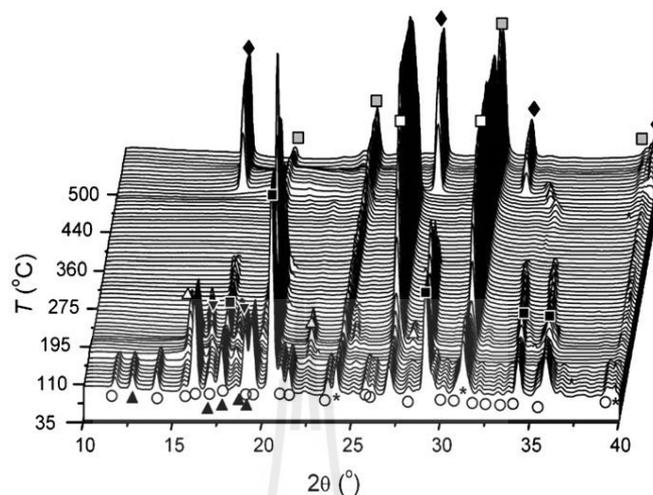

Figure 2.5 In situ SR-PXD data for the dehydrogenation of $\text{LiBH}_4\text{-NaAlH}_4$: ○ LiAlH_4 , ■ NaBH_4 , ▲ *o*- LiBH_4 , ▼ *h*- LiBH_4 , △ Li_3AlH_6 , □ Al+LiH , ◻ AlB_2 , ◆ LiAl , and * TiB_2 (Dorthe *et al.*, 2010).

From Figure 2.5, the formation of AlB_2 is observed about 450 °C, which destabilizes boron and may be optimized to eliminate the release of diboran (B_2H_6). The pressure for dehydrogenation is reduced by the formation of LiAl . Moreover, the rehydrogenation of $\text{LiBH}_4\text{-NaAlH}_4$ composite could be reversible partially at 400 °C under 110 bar H_2 , where the operating condition was milder than pure LiBH_4 (600 °C, 350 bar H_2).

2.3 Nanoconfinement in nanoporous scaffolds

Further approach to improve de/rehydrogenation kinetics is confinement of light metal hydrides in nanoporous scaffolds. Zhang *et al.* (2007) reported that LiBH_4 nanoparticles supported by disordered mesoporous carbon CMK-3 showed favorable

latent heat of dehydrogenation (40 kJ/mol H₂), large amount of dehydrogenation capacity (14 wt.% H₂) below 600 °C, and reversible capacity of 6.0 wt.% H₂ at 350 °C. Gross *et al.* (2008) demonstrated that the desorption temperature of LiBH₄ was lowered by 75 °C and the dehydrogenation rate at 300 °C increased up to 50 times, when LiBH₄ was incorporated into nanoporous structure of carbon scaffold. Furthermore, nanoconfined LiBH₄ showed a reversible hydrogen uptake (75 % of original capacity) at relatively mild conditions of 100 bar H₂, 400 °C for 2 h. Next, Liu *et al.* (2010) investigated the wetting and decomposition behavior of LiBH₄ in the presence of highly ordered nanoporous hard carbon (NPC) with hexagonally packed (2 nm diameter columnar pores). The confinement of LiBH₄ in small pores showed low temperatures of phase transition and melting of LiBH₄ as well as the significant decrease of the onset desorption temperature with respect to bulk LiBH₄. Most significantly, their results suggested that diborane release was suppressed during the decomposition of nanoconfined LiBH₄. For nanoconfined NaAlH₄, Nielsen *et al.* (2014) studied nanoconfined NaAlH₄ in nanoporous scaffolds with different surface areas, pore volumes, and pore sizes. Carbon aerogel scaffold (CAS) was obtained by pyrolyzing at 950 °C under CO₂ flow (CO₂-activated CAS). They found that by using CO₂-activated technique surface area and pore volume of CAS were significantly increased as compared with that prepared by using N₂ as flowed gas. The content of NaAlH₄ melt infiltrated into CO₂-activated CAS was up to 91 mol%, significantly higher than that into CAS prepared by using N₂-flowed gas (52 mol%). Furthermore, the stability of nanoconfined NaAlH₄ over several cycles of hydrogen release and uptake was significantly improved by the CO₂-activated CAS due to interaction between NaAlH₄ and CAS. However, the disadvantages of nanoconfinement in

nanoporous carbon scaffolds are high operating pressure and temperature for de/rehydrogenation as well as oxidation of metal hydrides. Therefore, new host materials for nanoconfinement are expected not only to reduce pressure and temperature for de/rehydrogenation, but also to prevent metal hydrides from air and humidity.

Interestingly, Jeon *et al.* (2011) reported the synthesis of an air-stable composite material consisting of Mg nanocrystals (NCs) in poly (methyl methacrylate) (PMMA). PMMA shows high permeability ratio of H₂/O₂ (ratio of 42.9 at 35 °C). In this work, PMMA was used to keep Mg away from water and oxygen but let hydrogen in or out freely (Wang *et al.*, 2008; Liang *et al.*, 2011; Mark, 1999). They found that the sample could absorb 5.97 wt.% H₂ at 200 °C under 35 bar H₂ within 80 min, while Mg powder could not absorb hydrogen in the same condition. Moreover, prevention of Mg nanoparticles from deterioration by oxygen and water was obtained by embedding in PMMA (Figure 2.6).

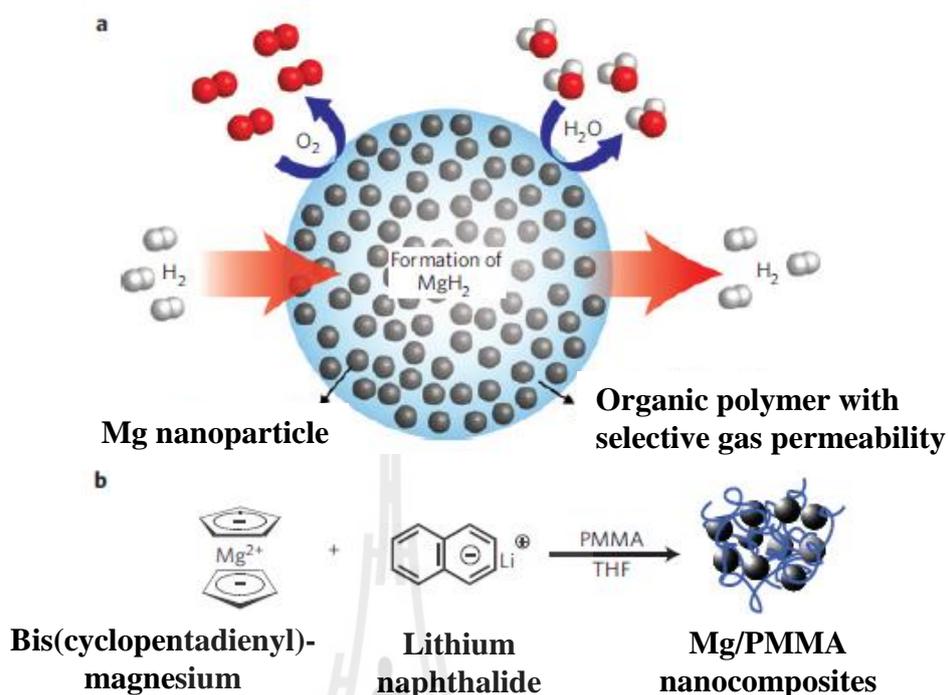

Figure 2.6 Mg NCs in a gas-barrier PMMA polymer matrix (Jeon *et al.*, 2011).

Next, Huang *et al.* (2014) investigated the dehydrogenation temperature of LiBH_4 compositing with poly (methyl methacrylate) (PMMA). They found that interaction between LiBH_4 and PMMA led to fast H_2 release at low temperature. Meanwhile, PMMA not only can protect LiBH_4 from water and oxygen, but also let hydrogen in and out freely. LiBH_4 compositing with PMMA started to dehydrogenate at $53\text{ }^\circ\text{C}$ and released 5.2 wt.% H_2 at $162\text{ }^\circ\text{C}$ within 1 h. It could be concluded that PMMA could prevent deterioration of LiBH_4 in the atmosphere and could reduce its dehydrogenation temperature.

Recently, Goslawit-Utke *et al.* (2014) destabilized LiBH_4 by nanoconfinement in poly (methyl methacrylate)-co-butyl methacrylate (PcB) polymer matrix. On the basis of a butyl-branched chain, PcB has a superior amorphous degree as compared to PMMA, leading to higher free volume in the polymer matrix for H_2

permeability. They found that the onset dehydrogenation temperature of nanoconfined LiBH_4 in PcB was ~ 80 °C and it released 0.74 wt.% H_2 (8.8 wt.% H_2 with respect to LiBH_4 content) at 120 °C under vacuum within 4 h during the 1st dehydrogenation. Furthermore, the nanoconfined LiBH_4 -PcB could be rehydrogenated at mild condition of 140 °C under 50 bar H_2 for 12 h. However, the disadvantages of nanoconfined LiBH_4 -PcB are LiBH_4 /PcB interaction between boron (B) of LiBH_4 with methoxy ($-\text{OCH}_3$) group of PcB and partial thermal degradation of PcB polymer, resulting in the reduction of H_2 content release and uptake.

Therefore, in this work, we doped small amount of NaAlH_4 in nanoconfined LiBH_4 -PcB. NaAlH_4 is expected to decrease LiBH_4 /PcB interaction and improve thermal stability of PcB host by providing competitive interaction with PcB.

2.4 Research objectives

- 2.5.1 To prepare NaAlH_4 doped into nanoconfined LiBH_4 -PcB.
- 2.5.2 To study kinetic properties of nanoconfined LiBH_4 -PcB samples with and without NaAlH_4 .
- 2.5.3 To reduce LiBH_4 /PcB interaction and to improve thermal stability of PcB.

CHAPTER III

EXPERIMENT

3.1 Chemicals and materials

Poly (methyl methacrylate)-co-butyl methacrylate (PcB, MW = 75,000), 2 M lithium borohydride solution in THF (LiBH_4 , $\geq 90\%$, hydrogen storage grade), and sodium aluminium hydride (NaAlH_4 , $\geq 93\%$, hydrogen storage grade) were purchased from Sigma-Aldrich (St. Louis, MN, USA). Tetrahydrofuran (THF, HPLC grade) and n-hexane (AR grade) were purchased from QRëC™. Metallic sodium (Na) and benzophenone ($(\text{C}_6\text{H}_5)_2\text{CO}$) were purchased from Fluka chemika (Buchs, Switzerland).

3.2 Sample preparations

3.2.1 Purification of tetrahydrofuran

THF was pre-dried overnight by molecular sieves. Metallic Na and benzophenone of 5 and 20 g, respectively, were added to 500 mL of pre-dried THF (Schwartz, 1978). The mixture was refluxed under nitrogen atmosphere at 80 °C until a deep blue color was obtained. The mixture was distilled at 70 °C under nitrogen atmosphere to obtain anhydrous THF.

3.2.2 Precipitation of PcB

PcB of 20.4890 g was dissolved in 100 mL anhydrous THF with continuous stirring to obtain homogeneous polymer solution (20.0 %w/v). The PcB polymer

solution was precipitated in distilled n-hexane and dried at 90 °C for 24 h in vacuum oven to obtain dried PcB polymer powder.

3.2.3 Dissolving of NaAlH₄ in anhydrous tetrahydrofuran

NaAlH₄ powder of 0.3013 g was dissolved in 85 mL anhydrous THF and continuously stirred for several hours in the glove box to obtain NaAlH₄ solution (0.35 % w/v NaAlH₄ in THF).

3.2.4 Synthesis of nanoconfined LiBH₄ in PcB

The polymer solution was prepared by dissolving 5.0656 g of PcB in 20 mL anhydrous THF with continuous stirring. LiBH₄ solution of 15 mL was added into PcB polymer solution with continuous stirring under argon atmosphere in the glove box. The transparent gel was obtained after stirring the mixture of LiBH₄ and PcB for approximately 10 min. The LiBH₄-PcB gel was dried in the glove box to achieve the powder sample, containing 11.5 wt.% of LiBH₄, denoted as nano LiBH₄-PcB. With respect to the LiBH₄ content, theoretical hydrogen storage capacity of 1.60 wt.% was achieved.

3.2.5 Synthesis of nanoconfined LiBH₄-NaAlH₄ in PcB

PcB powder of 0.5144 g was dissolved in 5 mL anhydrous THF to obtain PcB polymer solution. The solutions of LiBH₄ and NaAlH₄ of 1.5 and 2 mL, respectively, were added into PcB polymer solution. The mixture was stirred for 1 h until transparent gel was achieved. The transparent gel was dried at room temperature in the glove box for several days to obtain nano LiBH₄-NaAlH₄-PcB powder sample, where the molar ratio of LiBH₄:NaAlH₄ was 10:0.5. The sample contained 11.2 and 1.2 wt.% of LiBH₄ and NaAlH₄, respectively. Due to small amount of NaAlH₄ doped,

it was considered as an additive, where H₂ storage capacity could be negligible. Thus, with respect to LiBH₄ content, theoretical hydrogen storage capacity of nano LiBH₄-NaAlH₄-PcB was calculated to be 1.55 wt.%.

3.3 Characterizations

3.3.1 Fourier transform infrared spectrometry (FTIR)

Fourier transform infrared (FTIR) spectra of standard samples (NaAlH₄, LiBH₄ and PcB) and nanoconfined samples of LiBH₄-PcB and LiBH₄-NaAlH₄-PcB were obtained by using a Bruker, IR spectrometer (Tensor 27). The sample was ground with anhydrous KBr (1:10 weight ratio of sample:anhydrous KBr) and pressed under 3 tons for 2 min to obtain KBr pellet. KBr pellet containing the sample was assembled in the FTIR machine on the direction of infrared. The spectrum was recorded in the range of 4000-400 cm⁻¹ with 32 scans at room temperature. Quantitative analysis was done by curve fitting technique using Magic plot program.

3.3.2 Scanning electron microscopy (SEM)

Morphologies of the samples were obtained using scanning electron microscopy (SEM) (Zeiss, Auriga). Nano LiBH₄-NaAlH₄-PcB powder sample was deposited on the sample holder by using silver glue (in *n*-butyl acetate). The powder sample was coated with platinum (Pt) by using a sputtering technique with a current of 30 mA for 30 s under vacuum. An energy-dispersive X-ray spectroscopy (EDS)-elemental mapping were managed by an apparatus from EDAX Inc., USA. Smart SEM and EDS Genesis programs were used for morphological studies and elemental analysis of the samples, respectively.

3.3.3 Kinetics measurement

De/rehydrogenation kinetics and hydrogen reproducibility of nano $\text{LiBH}_4\text{-PcB}$ and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ were studied by using a laboratory scale setup of a Sievert-type apparatus (Figure 3.1) (Gosalawit-Utke *et al.*, 2014). The powder sample of ~50–100 mg was packed in a high pressure stainless steel sample holder (316SS, Swagelok) under argon atmosphere in the glove box, and transferred to the Sievert-type apparatus. Two K-type thermocouples (-250-1,300 °C, SL heater) were attached to the sample holder and to the furnace for measuring the temperature change of the system during de/rehydrogenation. Pressure transducers (C206, Cole Parmer) in the pressure range of 0-500 psig and 0-3000 psig were used to measure the pressure change due to hydrogen desorption and absorption, respectively. Thermocouples and pressure transducers were connected to an AI210I module convertor data logger (from Wisco), measuring and transferring (every 1 s) the pressure and temperature changes of the sample to the computer for further evaluation. The samples was dehydrogenated by heating from room temperature to 120 °C (5 °C/min) under vacuum. Temperature was controlled by a PID temperature controller. In the case of rehydrogenation, the dehydrogenated powder sample was pressurized under 60 bar H_2 (purity = 99.999 %) at 120 °C for 12 h. Once the pressure reading was constant over a period of time, the amount of hydrogen released was calculated by the pressure change (ΔP) and the following equations:

$$(\Delta P)V = nRT$$

$$\text{H}_2 \text{ desorbed (wt.\%)} = [(n \times 2.0158)/\text{sample weight}] \times 100$$

where P , V , and T are hydrogen pressure (atm), volume of the system (L), and temperature (K), respectively, n is the number of hydrogen moles (mol), and R is gas constant ($0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}$).

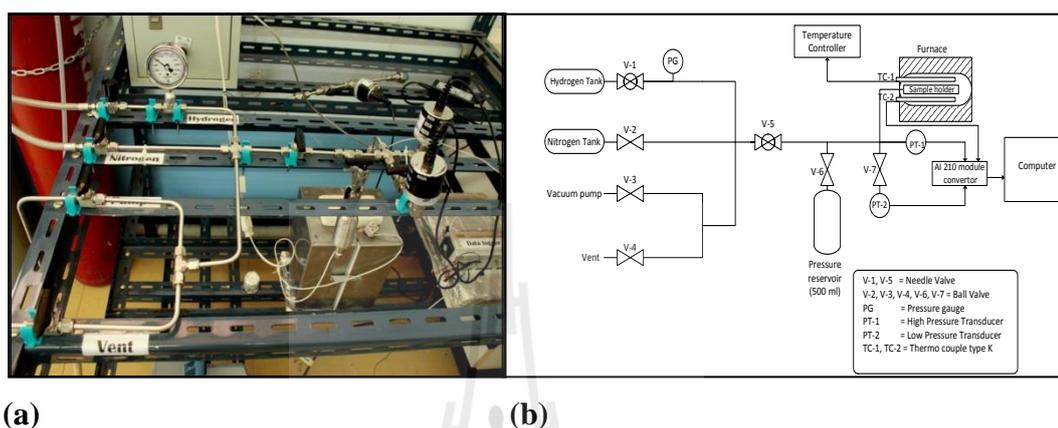

Figure 3.1 Picture (a) and schematic diagram (b) of Sievert-type apparatus.

3.3.4 X-ray photoelectron spectroscopy (XPS)

X-ray photoelectron spectroscopy was carried out at the Siam Photon Laboratory, BL3.2a in the Synchrotron Light Research Institute (Public Organization), Nakhon Ratchasima, Thailand. The powder samples of LiBH_4 , nano $\text{LiBH}_4\text{-PcB}$, and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ were held on the sample holders by using carbon glue tape in the glove box atmosphere. Prior to the measurements, all prepared samples were placed in an ultrahigh vacuum chamber for approximately 6 h. The photon energy of 400 eV was used to detect the signals of Li 1s and B 1s. Each element was investigated at the kinetic energy step of 0.1 eV for 5 scans by using an CLAM2 analyzer. The multi spectra were analyzed by using a macro XPS MS Excel 2007 (Windows XP) software.

3.3.5 Nuclear magnetic resonance (NMR) measurement

Solid-state ^{11}B , ^{27}Al and ^{23}Na magic angle spinning (MAS) nuclear magnetic resonance (NMR) spectra of LiBH_4 , NaAlH_4 , and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ were recorded by a Bruker ASCENDTM 500 spectrometer using a BL4 VNT probe for 4 mm outer diameter rotors. The powder sample was tightly packed in a zirconia end-capped tube in the glove box, and solid-state MAS NMR measurements were carried out at 302 K. Solid-state MAS NMR experiments employed a rotation frequency of 10 kHz. The excitation pulse lengths of ^{11}B and ^{27}Al MAS NMR were 5 and 9.8 μs , respectively. The relaxation delays of ^{11}B , ^{27}Al , and ^{23}Na MAS NMR were 5 s. The ^{11}B , ^{27}Al , and ^{23}Na chemical shifts were detected in part per million (ppm) relative to neat boric acid (H_2BO_3), aluminium oxide (Al_2O_3), and NaCl, respectively.

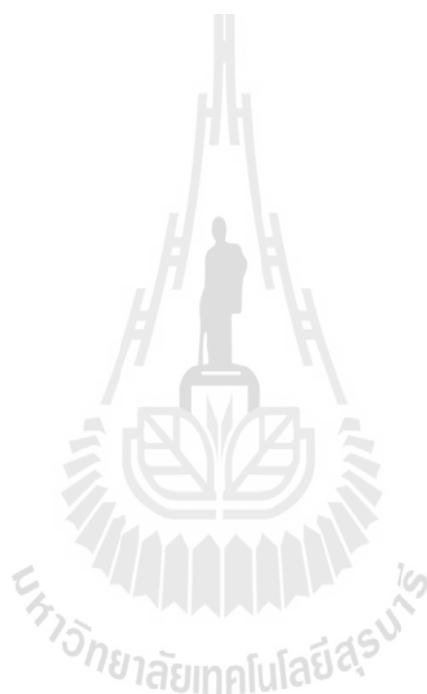

3.3.6 Powder X-ray diffraction (XRD) measurements

Powder X-ray diffraction patterns of PcB, nano $\text{LiBH}_4\text{-PcB}$, and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ were obtained from a Bruker D8 Advance by using a $\text{CuK}\alpha$ ($\lambda = 0.15406\text{ nm}$) radiation. The experiments were done in step scan mode with a step interval of $0.500^\circ/\text{s}$ (40 mV and 40 mA) over the 2θ range of $10\text{-}80^\circ$. The powder sample was packed in a sample holder under argon atmosphere in the glove box and covered by a plastic dome made from PMMA.

3.3.7 Gas analysis

The analyses of gases released during dehydrogenation of nano $\text{LiBH}_4\text{-PcB}$ and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ were carried out by connecting a manometric PCTPro-2000 apparatus with a residual gas analyzer (RGA200, Setaram, France) by using a $1/8''$ stainless steel tube. The powder sample ($\sim 200\text{ mg}$) was loaded in the sample

holder and transferred to the PCTPro–2000 apparatus. The measurement was done by heating the powder sample from room temperature to 300 °C (5 °C/min) under vacuum.

CHAPTER IV

RESULTS AND DISCUSSION

4.1 Dissolving of NaAlH₄ in anhydrous tetrahydrofuran

In order to confirm the successful dissolving of NaAlH₄ in THF, Fourier transform infrared spectrometer (FTIR) was used to characterize NaAlH₄ and dissolved NaAlH₄ in THF. NaAlH₄ exhibits characteristic vibrational peaks of [AlH₄]⁻ stretching and bending at 1636 and 888 cm⁻¹, respectively, (Figure 4.1 (a)) corresponding to the FTIR spectrum of NaAlH₄ previously reported (Rafi *et al.*, 2012). For dissolved NaAlH₄ in THF, all the characteristic peaks corresponding to NaAlH₄ are observed (Figure 4.1 (b)). This confirms successful dissolving of NaAlH₄ in THF.

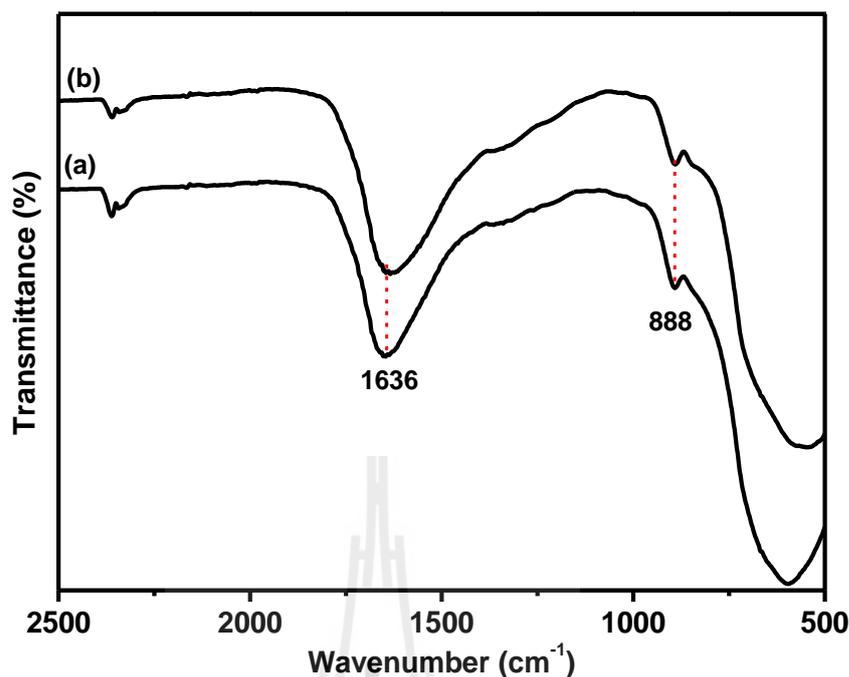

Figure 4.1 FTIR patterns of NaAlH₄ (a) and dissolved NaAlH₄ in THF (b).

4.2 Dispersion of LiBH₄ and NaAlH₄ in PcB polymer matrix

To investigate the dispersion of LiBH₄ and NaAlH₄ in PcB polymer matrix, SEM and EDS-mapping experiments of nano LiBH₄-NaAlH₄-PcB sample were done. Figure 4.2 (A) shows SEM image of nano LiBH₄-NaAlH₄-PcB and the elemental maps corresponding to the area depicted (Figures 4.2 (B-E)). From Figures 4.2 (B-E), good dispersion of carbon (C) from PcB, boron (B) from LiBH₄, and sodium (Na) and aluminium (Al) from NaAlH₄ are detected all over sample bulk. From Figure 4.2 (F), the signals of C and oxygen (O) from PcB are observed together with those of Na, Al, and B from NaAlH₄ and LiBH₄, respectively, as well as platinum (Pt) from surface coating. The missing of lithium (Li) signal from LiBH₄ can be due to the limitation of EDS technique to light element. From these results, it can be confirmed that LiBH₄ and NaAlH₄ are well dispersed into PcB polymer matrix.

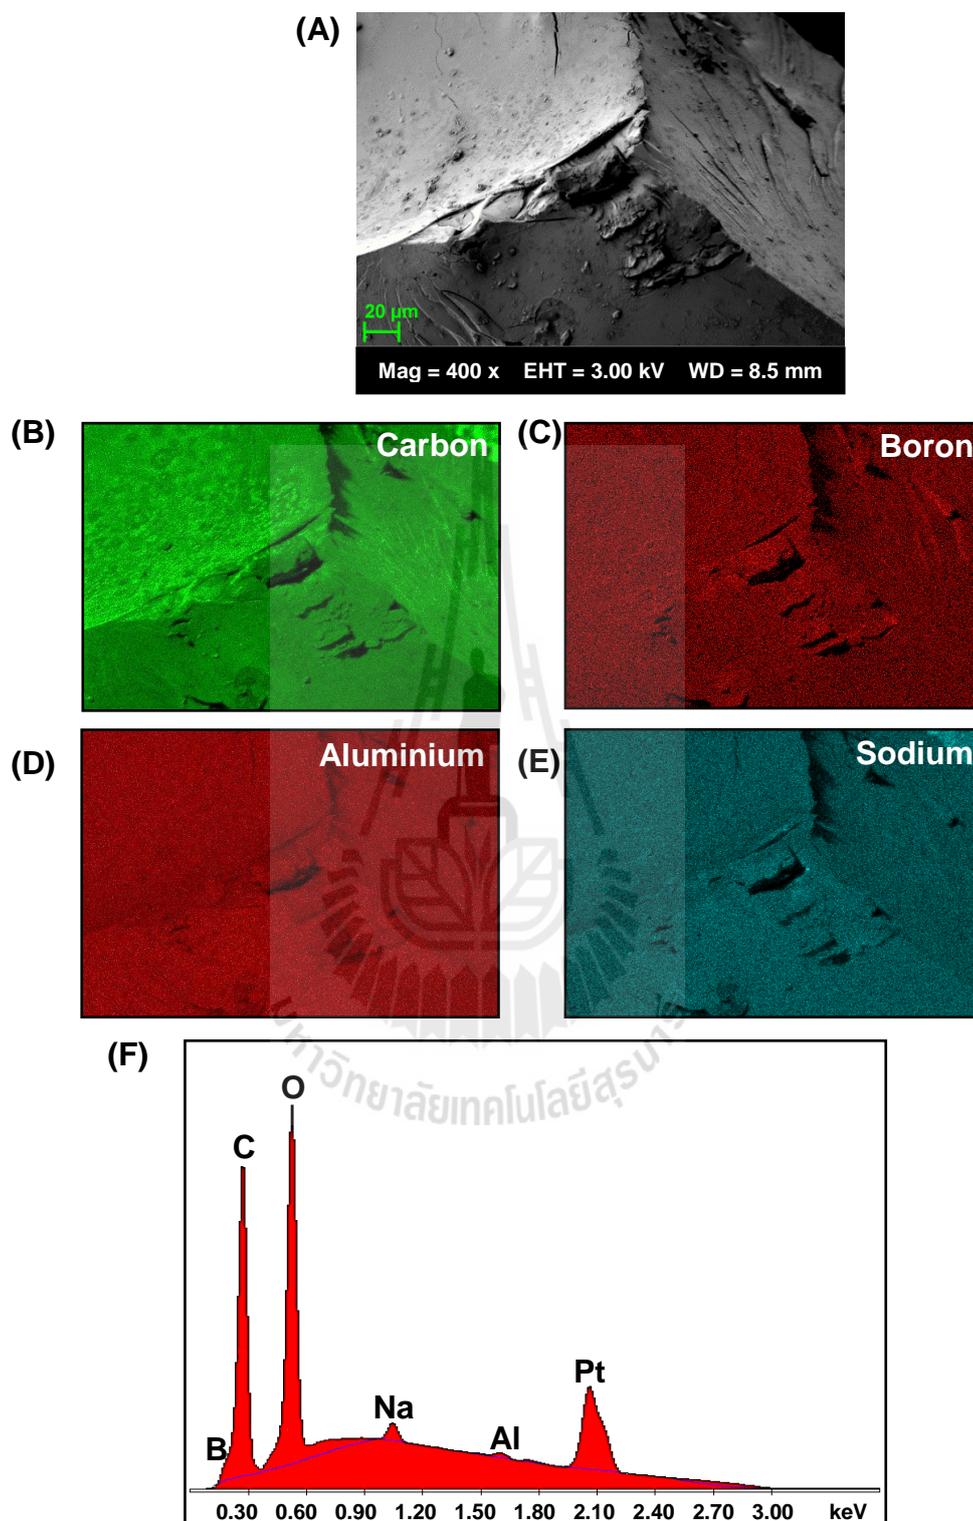

Figure 4.2 SEM image of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ (A), carbon mapping (B), boron mapping (C), aluminium mapping (D), sodium mapping (E), and quantitative elemental analysis (F).

4.3 Kinetic properties

To evaluate the performance of the hydrogen storage material, the storage capacity obtained from the sample must be compared with theoretical values. Theoretical hydrogen storage capacities of nanoconfined samples based on the amount of all components in the mixtures are calculated (Table 4.1). With respect to PcB polymer content in the samples, nano LiBH₄-PcB contains LiBH₄ of 11.5 wt.%, while nano LiBH₄-NaAlH₄-PcB consists of LiBH₄ and NaAlH₄ of 11.2 and 1.2 wt.%, respectively. On the basis of dehydrogenation of LiBH₄ (equation (4)), where 13.8 wt.% H₂ are theoretically released, the theoretical hydrogen storage capacity of the nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB are calculated to be 1.60 and 1.55 wt.%, respectively (Table 4.1).

Table 4.1 Amount of all components and theoretical hydrogen storage capacities of nanoconfined samples.

Nanoconfined samples	Amount of all components (wt.%)			Theoretical H ₂ capacity (wt.%)
	PcB	LiBH ₄	NaAlH ₄	
LiBH ₄ -PcB	88.5	11.5	-	1.60
LiBH ₄ -NaAlH ₄ -PcB	87.6	11.2	1.2	1.55

To study the dehydrogenation kinetics, hydrogen release and uptake cycles of nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB were performed by using Sievert-type apparatus. Dehydrogenation and rehydrogenation were done at the same temperature of 120 °C under vacuum and 60 bar H₂, respectively. The amount of gases desorbed due to thermal degradation (at 120 °C under vacuum) of PcB polymer

matrix and NaAlH₄-PcB composite are 0.04 and 0.005 wt.%, respectively. Hydrogen content released from nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB is obtained from total amount of gas release subtracted with those of PcB and NaAlH₄-PcB composite, respectively. From Figure 4.3 (A), the 1st dehydrogenation cycle of nano LiBH₄-PcB releases 0.78 wt.% H₂ (49 % H₂ with respect to theoretical hydrogen storage capacity) within 4 h. The inferior amount of H₂ released during 1st dehydrogenation (0.78 wt.% H₂) with respect to theoretical value (1.60 wt.% H₂) could be due to the interaction between LiBH₄ and PcB polymer chains (B---OCH₃), discussed in the previous studies (Gosalawit-Utke *et al.*, 2014). Afterwards, the dehydrogenated sample from the 1st dehydrogenation was rehydrogenated at 120 °C under 60 bar H₂ for 12 h. It results in desorbed hydrogen of only 0.32 wt.% H₂ during the 2nd dehydrogenation (20 % H₂ with respect to theoretical hydrogen storage capacity). The reduction of H₂ content released in the 2nd cycle with respect to the 1st one could be due to the greater interaction between LiBH₄ and PcB after cycling and thermal degradation of PcB polymer host during cycling under temperature and pressure as previously discussed (Gosalawit-Utke *et al.*, 2014). The latter leads to the inferior nanoconfinement of LiBH₄ in PcB polymer matrix. Moreover, the higher the interaction of LiBH₄/PcB (B---OCH₃), the lower the [BH₄]⁻ content, resulting in the lower H₂ storage capacity. In the case of nano LiBH₄-NaAlH₄-PcB, it exhibits H₂ desorption of 1.29 and 0.67 wt.% H₂ (83 and 43 % H₂ with respect to theoretical hydrogen storage capacity, respectively) during the 1st and 2nd dehydrogenations, respectively (Figure 4.3 (B)). It should be noted that nano LiBH₄-NaAlH₄-PcB shows not only higher H₂ desorption content with respect to nano LiBH₄-PcB (the 1st and 2nd cycles), but also faster desorption kinetics. For example, the dehydrogenation

of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ is completed within 1 h, while that of nano $\text{LiBH}_4\text{-PcB}$ requires up to 4 h. Fast kinetics of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ could be due to the catalytic effects of NaAlH_4 on dehydrogenation of LiBH_4 (Shi *et al.*, 2008).

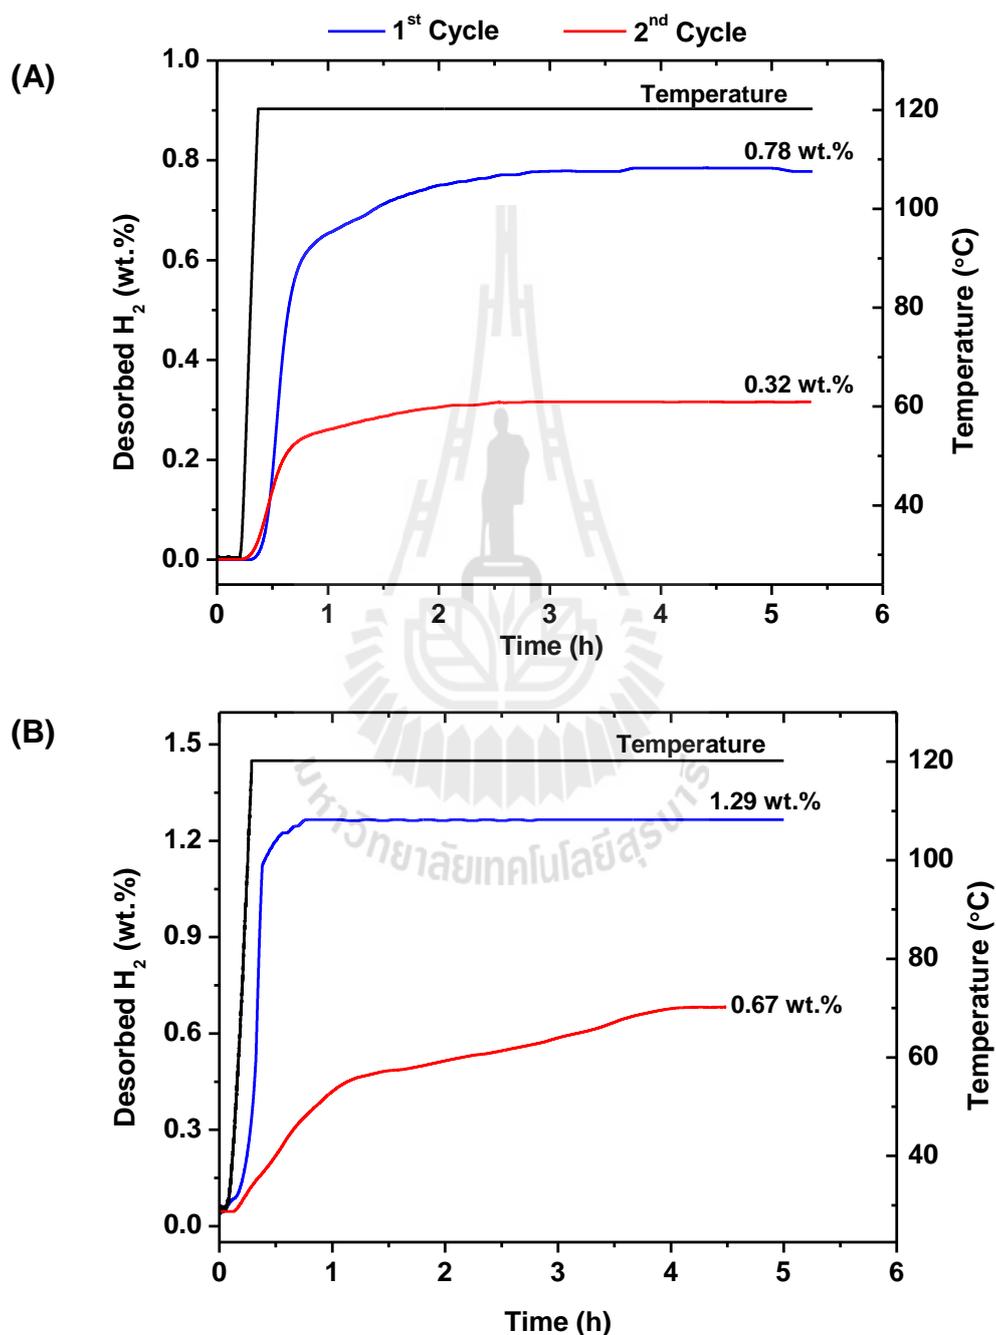

Figure 4.3 Hydrogen desorption 1st and 2nd cycles of nano $\text{LiBH}_4\text{-PcB}$ (A) and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ (B).

4.4 Reversibility

In order to investigate the characteristics peak of reference materials and to study reversibility of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$, FTIR technique was used.

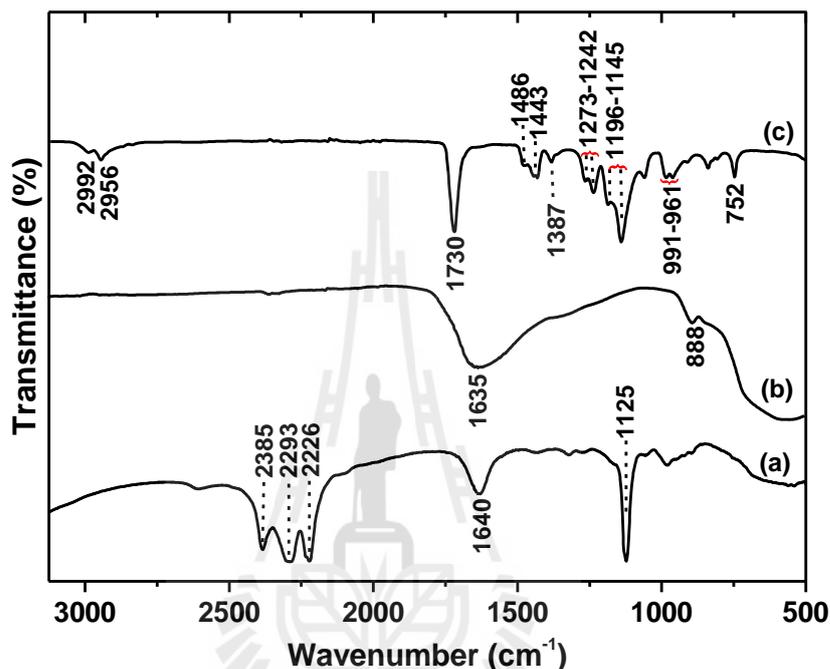

Figure 4.4 FTIR spectra of LiBH_4 (a), NaAlH_4 (b), and PcB (c).

For the reference materials, bulk LiBH_4 reveals the triplet peaks of B–H bond stretching at 2385, 2293, and 2226 cm^{-1} , while that of bending is at 1125 cm^{-1} (Figure 4.4 (a)). The peak at 1640 cm^{-1} refers to O–H bond from oxidation of LiBH_4 in ambient condition during the experiment (Yang *et al.*, 2014). NaAlH_4 exhibits vibrational peaks of $[\text{AlH}_4]^-$ stretching and bending at 1635 and 888 cm^{-1} , respectively (Rafi *et al.*, 2012) (Figure 4.4 (b)). For PcB, Figure 4.4 (c) shows a vibrational peak corresponding to C–H stretching at 2992–2956 cm^{-1} and C=O stretching of ester group at 1730 cm^{-1} . The vibrational peaks at about 1486 and 1443 cm^{-1} belong to asymmetric bending vibrations of (C– CH_2) and (C– CH_3) bonds, respectively. The two

peaks at 1387 and 752 cm^{-1} are in accordance with α -methyl group vibration. The two doublet bands at 1273–1242 and 1196–1154 cm^{-1} belong to C–O stretching of ester group and that at 991–961 cm^{-1} refers to C–H bending (Swain *et al.*, 2010).

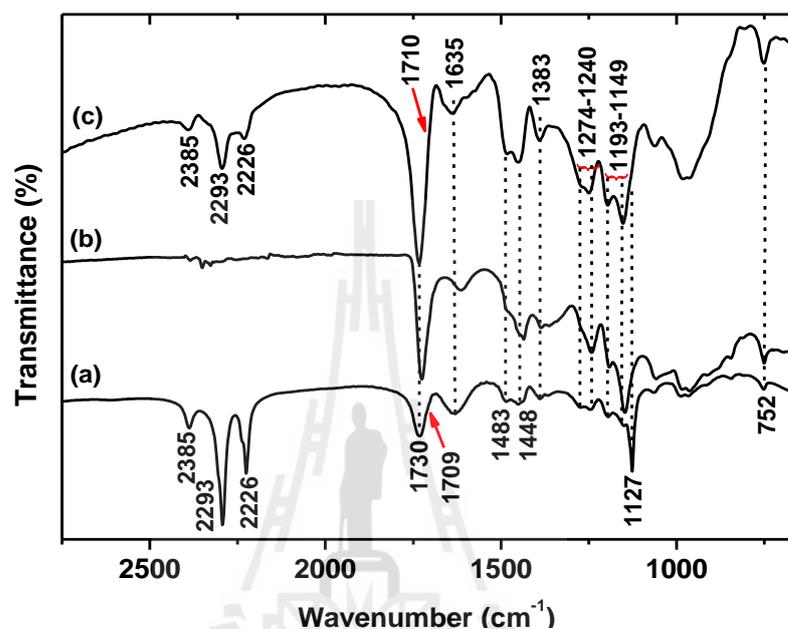

Figure 4.5 FTIR spectra of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ before desorption (a), after desorption (b), and after absorption (c).

In the case of the nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$, the sample before desorption shows characteristic peaks of $[\text{BH}_4]^-$ stretching (2385, 2293, and 2226 cm^{-1}) and bending (1127 cm^{-1}) of LiBH_4 together with all peaks of PcB (Figure 4.5 (a)). This suggests the existence of LiBH_4 in nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$. Moreover, the spectrum shows a small shoulder at 1709 cm^{-1} referring to not only $\text{Li}^+\text{---O}=\text{C}$ interaction (Lim *et al.*, 2008) formed between LiBH_4 and PcB, but also probably $\text{Na}^+\text{---O}=\text{C}$ interaction between NaAlH_4 and PcB. From the previous work, vibrational peak of B–O bonds due to B--- OCH_3 interaction, hinting at LiBH_4/PcB interaction was observed as a sharp peak at 1383 cm^{-1} (Gosalawit–Utke *et al.*, 2014). However,

for nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$, this vibration is not obviously detected (Figure 4.4 (a)). This could be due to the fact that B---OCH₃ interaction (LiBH_4/PcB interaction) is reduced by adding small amount of NaAlH_4 in nano $\text{LiBH}_4\text{-PcB}$, further discussed and confirmed in section 4.5. In the case of the sample after desorption, all vibrational peaks of PcB are still observed as in case of sample before dehydrogenation. However, the vibrational peaks of B-H bond of LiBH_4 are not observed, demonstrating complete dehydrogenation of LiBH_4 (Figure 4.5 (b)). For the sample after rehydrogenation, the vibrational peaks of B-H bond from LiBH_4 are recovered, referring to successful reversibility of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ (Figure 4.5 (c)).

4.5 LiBH_4/PcB interaction and prevention of LiBH_4 oxidation in air

In order to quantitatively determine the reduction of LiBH_4/PcB (B---OCH₃) interaction, quantitative analysis by FTIR technique was carried out. Relative concentration (or amount) of the phase of interest with respect to the reference can be quantitatively determined by the ratio of their FTIR peak area (Pierce *et al.*, 1990 and Xiong *et al.*, 2013). In this work, phase of interest and reference are B-H ($\nu(\text{B-H})$) and C=O ($\nu(\text{O=C})$) stretching from LiBH_4 and PcB, respectively. The more the ratio of peak area of $\nu(\text{B-H})/\nu(\text{O=C})$, the lower the LiBH_4/PcB (B---OCH₃) interaction.

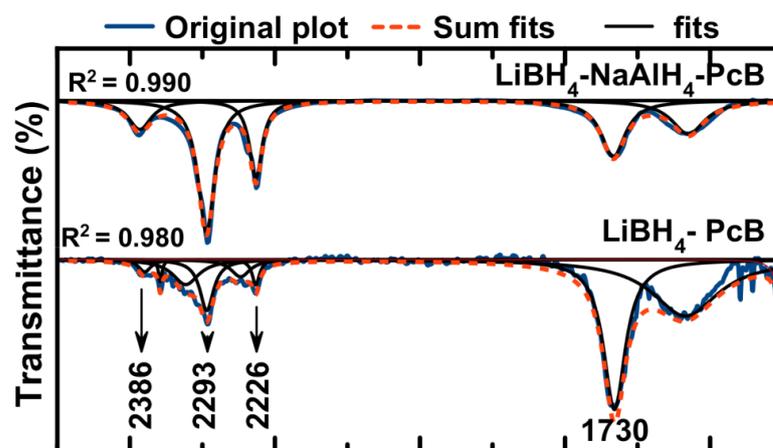

Figure 4.6 Curves fitting of FTIR spectra of nano $\text{LiBH}_4\text{-PcB}$ and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$.

This results in the higher content of $[\text{BH}_4]^-$ for dehydrogenation and increase of H_2 storage capacity. The peak areas of $\nu(\text{B-H})$ (in the range of $2386\text{--}2226\text{ cm}^{-1}$) and $\nu(\text{O=C})$ (at 1730 cm^{-1} and the shoulder due to $\text{Li}^+/\text{Na}^+\text{---O=C}$ interaction at $1710\text{--}1708\text{ cm}^{-1}$) were calculated by curve fitting method using Magic Plot program. The curve fitting results of FTIR spectra of nano $\text{LiBH}_4\text{-PcB}$ and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ are shown in Figure 4.6. The peak area of both vibrations ($\nu(\text{B-H})$ and $\nu(\text{O=C})$) as well as the ratio of their peak area ($\nu(\text{B-H})/\nu(\text{O=C})$) calculated from Figure 4.6 are summarized in Table 4.2.

Table 4.2 Peak area of B–H stretching, O=C stretching, and $\nu(\text{B-H})/\nu(\text{O=C})$ ratio of nanoconfined samples.

Nanoconfined samples	Peak area		$\nu(\text{B-H})/\nu(\text{O=C})$ ratio
	$\nu(\text{B-H})$ (2226-2386 cm^{-1})	$\nu(\text{O=C})$ (1730 cm^{-1})	
LiBH ₄ -PcB	109.5	171.2	0.6
LiBH ₄ -NaAlH ₄ -PcB	48.4	17.1	2.8

From Table 4.2, the $\nu(\text{B-H})/\nu(\text{O=C})$ ratio of nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB are 0.6 and 2.8, respectively. Because of lower $\nu(\text{B-H})/\nu(\text{O=C})$ ratio, it is clear that the nano LiBH₄-PcB has higher B---OCH₃ interaction as compared with nano LiBH₄-NaAlH₄-PcB. Therefore, it can confirm that the interaction between LiBH₄ with PcB is reduced by adding small amount of NaAlH₄. With respect to the amount of hydrogen in the 1st cycle (Figures 4.3), the higher hydrogen content released from nano LiBH₄-NaAlH₄-PcB with respect to that of nano LiBH₄-PcB can be due to the reduction of B---OCH₃ interaction. The reduction of LiBH₄/PcB interaction can be due to the competitive interaction of partial [AlH₄]⁻ from NaAlH₄ with alkoxy (-OCH₃ and/or -OC₄H₉) groups of PcB. The interaction between [AlH₄]⁻ and alkoxy groups (-OCH₃ and/or -OC₄H₉) is confirmed and discussed in solid-state MAS NMR results.

Moreover, to confirm the ability to prevent hydride deterioration in air of nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB as well as the reduction of LiBH₄/PcB (B---OCH₃) interaction after adding small amount of NaAlH₄ into nano LiBH₄-PcB, X-ray photoelectron spectroscopy (XPS) was used to investigate the elemental

compositions and the local chemical environment of the target elements in the sample surface (up to 10 nm depth). From Figure 4.7 (a), Li 1s of bulk LiBH₄ shows a peak of Li₂O at 55 eV (Deprez *et al.*, 2011). In the case of B 1s, formations of B_xO_y (x/y = 3) and B₂O₃ are observed at 187 and 192 eV, respectively (Alexander *et al.*, 2000; Deprez *et al.*, 2011). The formations of Li₂O, B_xO_y (x/y = 3), and B₂O₃ refer to oxidation of LiBH₄ with oxygen or humidity in air. Moreover, the signal of LiBH₄ in Li 1s and B 1s spectra is not detected (Figure 4.7 (a)), hinting at instability of LiBH₄ under ambient condition (25 °C under atmospheric pressure). For nanoconfined samples, prior to the XPS experiments the samples were left in ambient environment (25 °C under atmospheric pressure) for 3 days. From Figure 4.7 (b) and (c), Li 1s of both nanoconfined samples shows characteristic peaks of LiH and LiBH₄ at 54.5 and 56.2 eV, respectively (Haipinga *et al.*, 2011; Fang, *et al.*, 2011). The signals of LiBH₄ found in Li 1s spectra of both nanoconfined samples confirmed that PcB is able to prevent oxidation of LiBH₄ under ambient condition. For LiH formation, it suggests partial dehydrogenation of LiBH₄ during nanoconfinement, in agreement with the inferior hydrogen content released with respect to theoretical value during the 1st dehydrogenation (Figure 4.3). In the case of B 1s, both nanoconfined samples reveal characteristic peaks of B_xO_y (x/y = 3) and LiBH₄ at 187 and 188 eV, respectively (Haipinga *et al.*, 2011; Deprez *et al.*, 2011). The formation of B_xO_y (x/y = 3) in case of nanoconfined samples hints at LiBH₄/PcB interaction formed between [BH₄⁻] of LiBH₄ with -OCH₃ of PcB (B---OCH₃ interaction) (Gosalawit-Utke *et al.*, 2014).

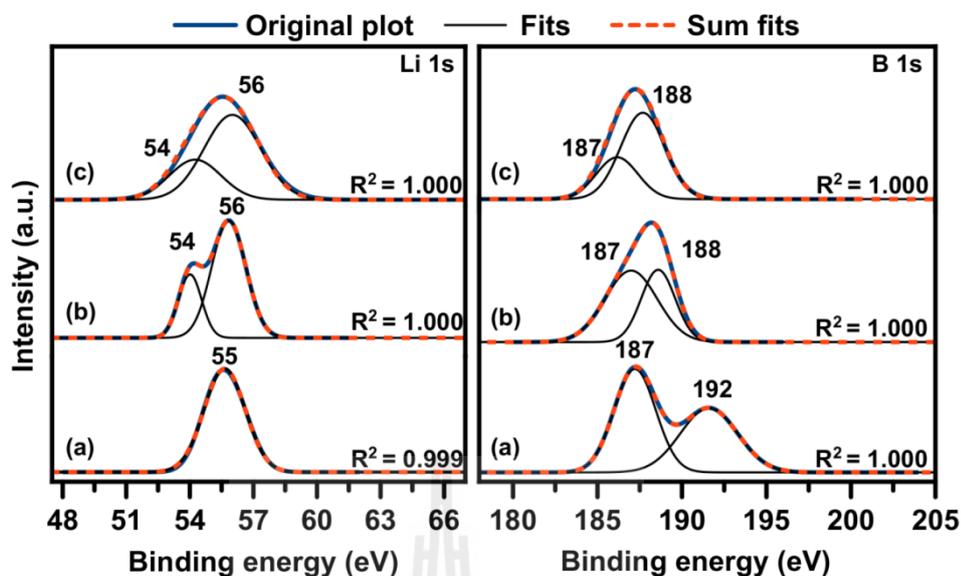

Figure 4.7 Li 1s and B 1s XPS spectra of bulk LiBH₄ (a), nano LiBH₄-PcB (b), and nano LiBH₄-NaAlH₄-PcB (c).

However, the relative amount of B_xO_y (from B---OCH₃ interaction) with respect to LiBH₄ obtained from nano LiBH₄-NaAlH₄-PcB is lower than that of nano LiBH₄-PcB (B 1s spectra in Figures 4.7 (b) and (c)), suggesting the reduction of LiBH₄/PcB interaction after adding small amount of NaAlH₄ into nano LiBH₄-PcB. This is in agreement with FTIR curve fitting results (Figure 4.6).

To further investigate the reason for the reduction of LiBH₄/PcB interaction, nano LiBH₄-NaAlH₄-PcB was studied by solid state ¹¹B, ²³Na, and ²⁷Al MAS NMR measurements. From Figure 4.8, ¹¹B MAS NMR spectrum of LiBH₄ shows a single peak at -41.5 ppm, corresponding to LiBH₄ reported elsewhere (Choi *et al.*, 2011). In the case of nano LiBH₄-NaAlH₄-PcB, the signal of LiBH₄ at -41.5 ppm is observed together with a shoulder at -42.7 ppm, corresponding to NaBH₄ (Figure 4.8 (a)) (Garroni *et al.*, 2011). This suggests partial reaction between LiBH₄ and NaAlH₄ to

produce NaBH_4 during sample preparation. Furthermore, the peaks of B–O bonds are found in the range of 0–20 ppm (MacKenzie and Smith, 2002), especially the main peak at 0.4 ppm corresponding to LiBH_4/PcB (B--- OCH_3) interaction, in agreement with B 1s XPS results (Figure 4.7 (c)). For ^{23}Na MAS NMR, NaAlH_4 and the nano $\text{LiBH}_4\text{--NaAlH}_4\text{--PcB}$ show a single peak at -9.6 ppm, corresponding to NaAlH_4 (Nielsen *et al.*, 2014; Liang *et al.*, 2011). In the case of ^{27}Al MAS NMR, NaAlH_4 shows a main peak at 95.6 ppm as well as a small peak at 81.3 ppm, corresponding to NaAlH_4 and aluminum oxide or hydroxide species (e.g., AlO_4) (Choi *et al.*, 2011), respectively. For nano $\text{LiBH}_4\text{--NaAlH}_4\text{--PcB}$, Figure 4.8 (a) shows the signals of NaAlH_4 (at 95.6 ppm) together with those of aluminium alkoxide ($\text{Al}(\text{OR})_3$) (at 50.1 and 43.6 ppm), where R could be either methyl ($-\text{CH}_3$) or butyl ($-\text{C}_4\text{H}_9$) group of PcB polymer branches (KřÍž *et al.*, 1984). A small peak at 22.2 ppm relates to $\beta\text{-AlH}_3$ (Hwang *et al.*, 2007) (Figure 4.8 (a)). It can be concluded that there is not only B--- OCH_3 interaction in nano $\text{LiBH}_4\text{--NaAlH}_4\text{--PcB}$, but also those of Al---OCH_3 and/or $\text{Al---OC}_4\text{H}_9$ interactions are observed. Therefore, by adding amount of NaAlH_4 in nano $\text{LiBH}_4\text{--PcB}$, competitive interaction of $[\text{AlH}_4^-]/\text{PcB}$ is accomplished, leading to the reduction of LiBH_4/PcB interaction, in accordance with FTIR and XPS results. Therefore, the H_2 content released during the 1st and the 2nd desorption of nano $\text{LiBH}_4\text{--NaAlH}_4\text{--PcB}$ is higher than that of nano $\text{LiBH}_4\text{--PcB}$ (Figures 4.3 (A) and (B)).

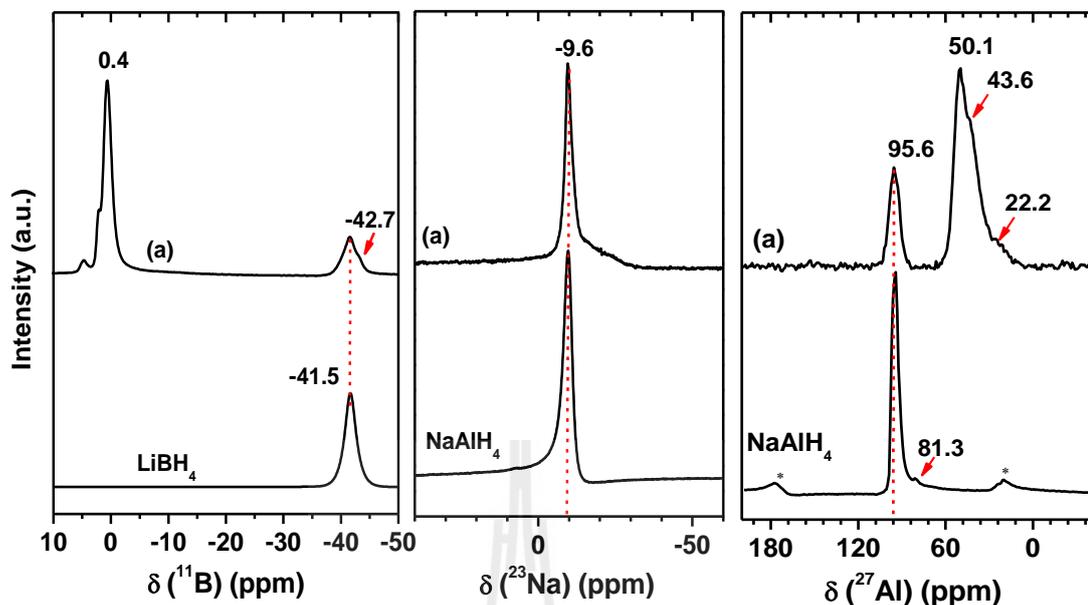

Figure 4.8 Solid state ^{11}B , ^{23}Na , and ^{27}Al MAS NMR of LiBH_4 , NaAlH_4 , and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ (a).

Furthermore, powder X-ray diffraction (XRD) of PcB and nanoconfined samples was carried out to study the effects of LiBH_4/PcB and $\text{NaAlH}_4/\text{PcB}$ interaction on d-spacing of PcB polymer chains. From Figure 4.9 (a), pure PcB shows broad peaks at 2θ values of 13.9° , 29.7° , and 42.0° indicating amorphous nature of PcB (Gosalawit-Utke *et al.*, 2014). For nanoconfined samples, splitting of XRD peak at 13.9° to higher and lower values is detected (Figures 4.9 (c) and (d)), referring to change of PcB polymer d-spacing. For nano $\text{LiBH}_4\text{-PcB}$, XRD peak at 13.9° splits into two peaks at 13.9° and 17.0° (Figure 4.9 (b)). Based on Bragg's Law, where $n\lambda = 2d\sin\theta$, enhancement of 2θ value means decrease of d-spacing. The peaks at 13.9° is a character of PcB polymer and at 17.0° should be due to the LiBH_4/PcB interaction (B-OCH_3 and $\text{Li}^+\text{-O=C}$). Because the LiBH_4/PcB interaction probably draws the PcB polymer chains to be closed to each other, d-spacing of PcB polymer decreases. In the case of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$, the peak shifts toward the higher and lower 2θ

values of 17.0° and 12.4° , respectively (Figure 4.9 (c)). For the peak at 17.0° , it refers to LiBH_4/PcB interaction as explained in the XRD pattern of nano LiBH_4/PcB (Figure 4.9 (b)). The peak at 12.4° leads to higher d-spacing of PcB polymer chains, probably relating to $\text{NaAlH}_4/\text{PcB}$ interaction. Due to the higher dissociation enthalpy of B-O bond ($\Delta H = 808 \text{ kJ/mol}$) as compared with that of Al-O bond ($\Delta H = 511 \text{ kJ/mol}$) (Luo, 2007), the interaction of LiBH_4/PcB is stronger than that of $\text{NaAlH}_4/\text{PcB}$. Therefore, the d-spacing of B-O bond is smaller than that of Al-O bond. Moreover, the atomic size of Li, smaller than that of Na, could probably corresponds to the lower d-spacing of PcB in nano $\text{LiBH}_4\text{-PcB}$ with respect to that of nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$. From these results, it can conclude that there is not only LiBH_4/PcB interaction observed, but also that of $\text{NaAlH}_4/\text{PcB}$ interaction is observed.

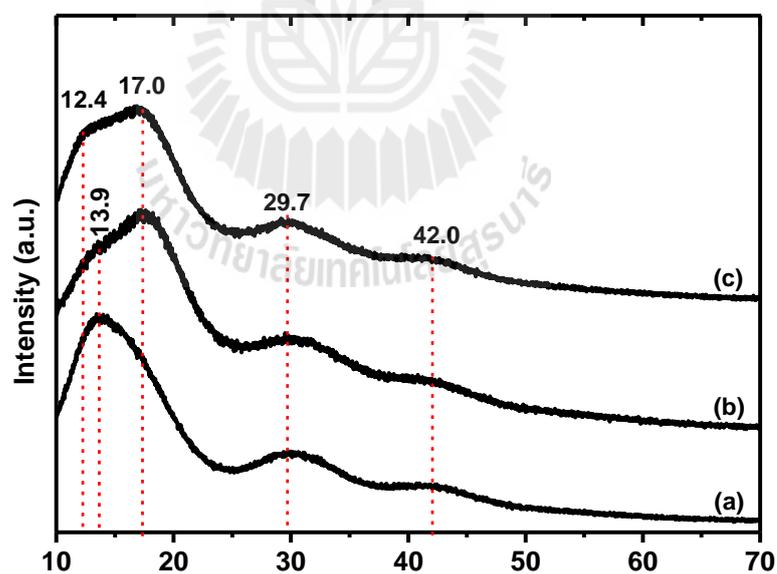

Figure 4.9 XRD patterns of PcB (a), nano $\text{LiBH}_4\text{-PcB}$ (b) and nano $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ (c).

4.6 Thermal stability

To study the effects of NaAlH₄ on thermal stability of nano LiBH₄-PcB, gas analysis was performed in the temperature range of 30-300 °C ($dT/dt = 5$ °C/min) under dynamic vacuum. From gas analysis results, the main gas released from nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB is hydrogen (H₂) together with gases due to thermal degradation of PcB; that is, methyl radical ($\bullet\text{CH}_3$), carbon monoxide (CO), methoxy radical ($\bullet\text{OCH}_3$), carbon dioxide (CO₂), and butoxy radical ($\bullet\text{OC}_4\text{H}_9$) (Figures 4.10 (A) and (C)) (Kashiwagi and Inabi, 1989; Rajkumar *et al.*, 2010; Chang *et al.*, 2001). Therefore, this can be concluded that not only H₂ releases from nanoconfined samples, but also other gases due to thermal degradation of PcB polymer. Figures 4.7 (B) and (D) are the plots between peak area of each gas signal versus temperature from gas analyses in Figures 4.7 (A) and (C), respectively. Nano LiBH₄-PcB shows onset temperature (T_i) of H₂ release at ~80 °C. The main hydrogen desorption temperature (T_p) is at 105 °C and the H₂ signal finishes (T_f) at 135 °C (Figures 4.7 (B)). In the case of nano LiBH₄-NaAlH₄-PcB, it starts (T_i) and finishes (T_f) at 95 and 165 °C, respectively, while the main H₂ desorption temperature (T_p) is at 125 °C (Figure 4.10 (D)). For thermal degradation of PcB from nano LiBH₄-PcB, combination of gases ($\bullet\text{CH}_3$, CO, $\bullet\text{OCH}_3$, CO₂, and $\bullet\text{OC}_4\text{H}_9$) are observed during dehydrogenation range (80-135 °C), and especially CO₂, $\bullet\text{CH}_3$ and $\bullet\text{OC}_4\text{H}_9$ are firstly detected approximately at onset dehydrogenation temperature (T_i) (~ 80 °C) (Figure 4.7 (B)). Moreover, significant amount of $\bullet\text{CH}_3$ (59 % with respect to the highest content of hydrogen released) is detected at ~145 °C. Considerable amount of gases obtained from thermal degradation of PcB during dehydrogenation of nano LiBH₄-PcB hits at thermal instability of PcB host. For nano LiBH₄-NaAlH₄-PcB, the peak

area of gases release due to thermal degradation of PcB is reduced, suggesting that thermal stability of PcB is improved by adding small amount of NaAlH₄.

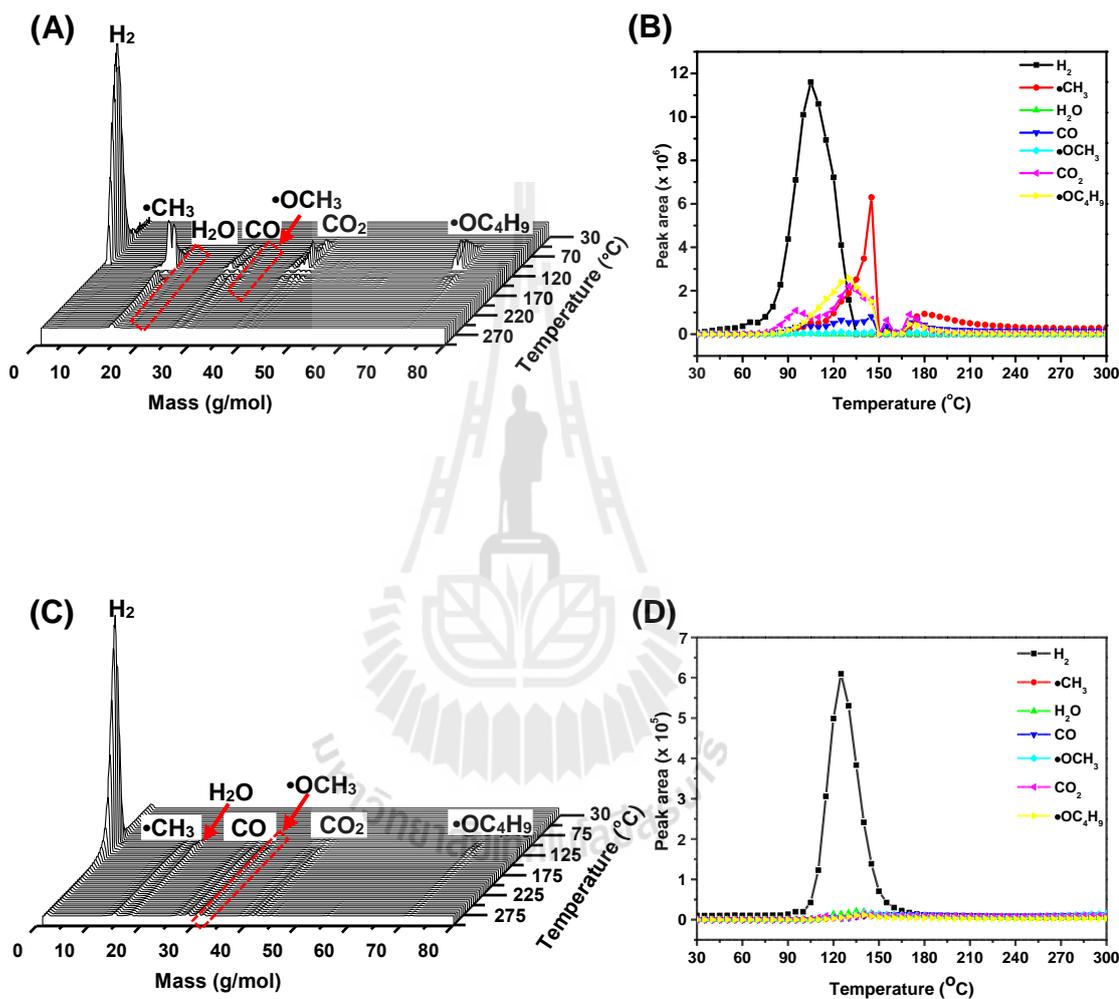

Figure 4.10 Gas analysis during dehydrogenation of nano LiBH₄-PcB (A), and nano LiBH₄-NaAlH₄-PcB (C), and peak area of gas desorption from thermal degradation of PcB with respect to H₂ at 120 °C of nano LiBH₄-PcB (B), and nano LiBH₄-NaAlH₄-PcB (D).

Moreover, the relative amounts of gases desorbed with respect to hydrogen content at dehydrogenation temperature (120 °C) of nanoconfined samples were studied.

Table 4.3 Amount of gas desorption from thermal degradation of PcB with respect to H₂ at 120 °C.

Nanoconfined samples	Desorption temperature (°C)			Amount of gases desorbed with respect to that of H ₂ at 120 °C (%)						
	T _i	T _p	T _f	•CH ₃	H ₂ O	CO	•OCH ₃	CO ₂	•OC ₄ H ₉	Total
LiBH ₄ -PcB	80	105	135	13.4	0	6.9	0.8	16.3	26.9	64.3
LiBH ₄ -NaAlH ₄ -PcB	95	125	165	1.0	2.8	1.1	1.3	1.1	0.6	7.9

T_i = Onset temperature, T_p = peak temperature and T_f = end temperature

From Table 4.3, the relative amounts of •CH₃, CO, •OCH₃, CO₂, and •OC₄H₉ with respect to H₂ content of nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB are totally 64.3 and 7.3 %, respectively. This hits at significant reduction of gases desorbed due to thermal degradation of PcB by adding small amount of NaAlH₄ in nano LiBH₄-PcB. This refers to significant improvement in thermal stability of PcB. The improvement in thermal stability of PcB is probably due to the interaction of PcB with metal hydrides; i.e., LiBH₄ and NaAlH₄, as explained in section 4.1.5, leading to the restriction of PcB polymer chain motion. Moreover, thermal stability of polymer could be improved by compositing with metal or metal ion. Thus, in the case of nano LiBH₄-NaAlH₄-PcB, not only Li⁺---O=C interaction is observed, but also that of Na⁺ from NaAlH₄ (Na⁺---O=C interaction) is probably achieved. As reported by Lekesiz *et al.* (2014), thermal stability of polystyrene-block-poly (2-vinylpyridine) (PS-b-

P2VP) polymer was improved by compositing with metal or metals ion (Co, Cr, and Au³⁺). They found that the more the interaction between polymer and metal (or metal ion), the higher the thermal stability.

CHAPTER V

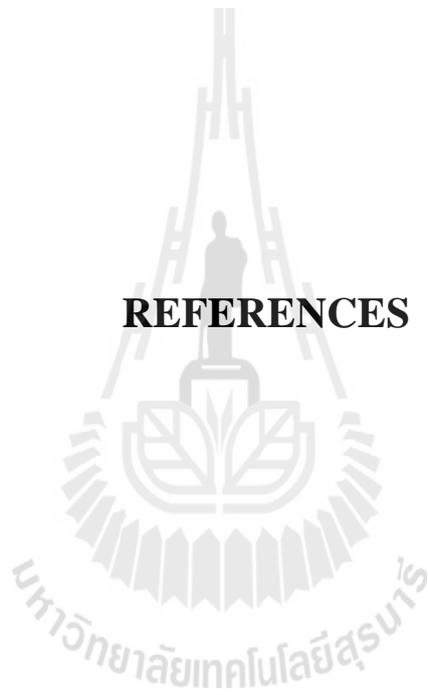

CONCLUSION

In this thesis, nano LiBH₄-NaAlH₄-PcB was proposed for reversible hydrogen storage. The reduction of LiBH₄/PcB interaction (B---OCH₃) and improvement of thermal stability of PcB polymer were developed by adding small amount of NaAlH₄ (1.2 wt.%) . The LiBH₄/PcB interaction of the nanoconfined samples was analyzed quantitatively by using FTIR technique, the ratio of the peak area between B-H stretching (from LiBH₄) and C=O stretching (from PcB) ($v(\text{B-H})/v(\text{C=O})$), corresponding to the relative amount of [BH₄]⁻ with respect to PcB, was determined. The more the ($v(\text{B-H})/v(\text{C=O})$) ratio, the higher the free [BH₄]⁻ content and the lower the LiBH₄/PcB interaction. The ($v(\text{B-H})/v(\text{C=O})$) ratio of the nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB were 0.6 and 2.8, respectively. Therefore, it could be confirmed that LiBH₄/PcB interaction was decreased by adding small amount of NaAlH₄. From the B 1s XPS result, the relative amount of B_xO_y (from B---OCH₃ interaction) with respect to LiBH₄ of nano LiBH₄-NaAlH₄-PcB was lower than that of nano LiBH₄-PcB. In addition, the solid state MAS NMR and XRD results of nano LiBH₄-NaAlH₄-PcB confirmed that the LiBH₄/PcB interaction was decreased due to the competitive reaction of [AlH₄]⁻ (of NaAlH₄) with -OCH₃ and/or -OC₄H₉ (of PcB). These result in increase of H₂ content desorbed during the 1st and 2nd dehydrogenations of nano LiBH₄-NaAlH₄-PcB as compared with nano LiBH₄-PcB. Moreover, the total amount of gases desorbed due to thermal degradation of PcB with

respect to H₂ content at 120 °C from nano LiBH₄-PcB and nano LiBH₄-NaAlH₄-PcB were 64.3 and 7.9 %, respectively. This could be due to not only the interaction of PcB at methoxyl and/or butoxyl groups with metal hydrides (LiBH₄ and NaAlH₄), but also that of carbonyl group (from PcB) with metal ions (Li⁺ and Na⁺). In conclusion, the reduction of LiBH₄/PcB interaction and the improvement of thermal stability of nano LiBH₄-PcB were obtained by doping with small amount of NaAlH₄.

APPENDIX

CALCULATION OF HYDROGEN CAPACITY

A.1 Calculation of theoretical hydrogen storage capacity

➤ Nano LiBH₄-PcB

Amount of PcB (5.0656g) and LiBH₄ (0.66 g), wt.% of LiBH₄ in PcB is calculated by:

$$\begin{aligned}\text{Wt.\% of LiBH}_4 &= 0.66 \text{ g} / (5.0656 \text{ g} + 0.66 \text{ g}) \times 100 \\ &= 11.53 \text{ wt.\%}\end{aligned}$$

From 13.8 wt.% of hydrogen released by pure LiBH₄, the theoretical of hydrogen capacity of nanoconfined LiBH₄-PcB is calculated by:

$$\begin{aligned}\text{Wt.\% of hydrogen} &= (13.8 \text{ wt.\%} \times 11.53 \text{ wt.\%}) / 100 \\ &= 1.60 \text{ wt.\% H}_2\end{aligned}$$

➤ Nano LiBH₄-NaAlH₄-PcB

Amount of PcB (0.5144), LiBH₄ (0.066) and NaAlH₄ (0.007), wt.% of LiBH₄ and NaAlH₄ in PcB is calculated by:

$$\begin{aligned}\text{Wt.\% of composite} &= 0.5144 \text{ g} + 0.066 \text{ g} + 0.007 \text{ g} \\ &= 0.5874 \text{ g}\end{aligned}$$

$$\begin{aligned}\text{Wt.\% of LiBH}_4 &= (0.066 \text{ g} / 0.5874 \text{ g}) \times 100 \\ &= 11.23 \text{ wt.\%}\end{aligned}$$

From 13.8 wt.% of hydrogen released by pure LiBH_4 , the theoretical of hydrogen capacity of LiBH_4 in nanoconfined $\text{LiBH}_4\text{-NaAlH}_4\text{-PcB}$ is calculated by:

$$\begin{aligned}\text{Wt.\% of hydrogen} &= (13.8 \text{ wt.\%} \times 11.23 \text{ wt.\%}) / 100 \\ &= 1.55 \text{ wt.\% H}_2\end{aligned}$$

A.2 Calculation of hydrogen desorption capacity

1. Nano $\text{LiBH}_4\text{-PcB}$

- 1st dehydrogenation

$$T = 120 \text{ }^\circ\text{C}$$

$$P_1 = -1.33 \text{ atm}$$

$$P_2 = -0.60 \text{ atm}$$

$$V = 0.024 \text{ L}$$

$$R = 0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}$$

$$(\Delta P)V = nRT$$

$$\begin{aligned}n &= [(-0.60 \text{ atm}) - (-1.33 \text{ atm})] \times 0.024 \text{ L} / [(0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}) \times 393 \text{ K}] \\ &= 5.43 \times 10^{-4} \text{ mol}\end{aligned}$$

$$\text{H}_2 \text{ desorbed (wt.\%)} = [(n \times 2.0158) / \text{sample weight}] \times 100$$

$$= [(5.43 \times 10^{-4} \text{ mol} \times 2.0158 \text{ g/mol}) / 0.1402 \text{ g}] \times 100$$

$$= 0.78 \text{ wt.\% H}_2$$

- 2nd dehydrogenation

$$P_1 = -1.33 \text{ atm}$$

$$P_2 = -1.04 \text{ atm}$$

$$\begin{aligned}n &= [(-1.04 \text{ atm}) - (-1.33 \text{ atm})] \times 0.024 \text{ L} / [(0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}) \times 393 \text{ K}] \\ &= 2.16 \times 10^{-4} \text{ mol}\end{aligned}$$

$$\begin{aligned} \text{H}_2 \text{ desorbed (wt.\%)} &= [(2.16 \times 10^{-4} \text{ mol} \times 2.0158 \text{ g/mol}) / 0.1402 \text{ g}] \times 100 \\ &= 0.32 \text{ wt.\% H}_2 \end{aligned}$$

2. Nano LiBH₄-NaAlH₄-PcB

- 1st dehydrogenation

$$T = 120 \text{ }^\circ\text{C}$$

$$P_1 = -1.29 \text{ atm}$$

$$P_2 = -0.60 \text{ atm}$$

$$V = 0.023 \text{ L}$$

$$R = 0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}$$

$$(\Delta P)V = nRT$$

$$\begin{aligned} n &= [(-0.60 \text{ atm}) - (-1.30 \text{ atm})] \times 0.023 \text{ L} / [(0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}) \times 393 \text{ K}] \\ &= 4.99 \times 10^{-4} \text{ mol} \end{aligned}$$

$$\begin{aligned} \text{H}_2 \text{ desorbed (wt.\%)} &= [(n \times 2.0158) / \text{sample weight}] \times 100 \\ &= [(5.43 \times 10^{-4} \text{ mol} \times 2.0158 \text{ g/mol}) / 0.0861 \text{ g}] \times 100 \\ &= 1.29 \text{ wt.\% H}_2 \end{aligned}$$

- 2nd dehydrogenation

$$P_1 = -1.33 \text{ atm}$$

$$P_2 = -1.04 \text{ atm}$$

$$\begin{aligned} n &= [(-0.90 \text{ atm}) - (-1.30 \text{ atm})] \times 0.023 \text{ L} / [(0.0821 \text{ L atm K}^{-1} \text{ mol}^{-1}) \times 393 \text{ K}] \\ &= 2.85 \times 10^{-4} \text{ mol} \end{aligned}$$

$$\begin{aligned} \text{H}_2 \text{ desorbed (wt.\%)} &= [(2.85 \times 10^{-4} \text{ mol} \times 2.0158 \text{ g/mol}) / 0.0861 \text{ g}] \times 100 \\ &= 0.67 \text{ wt.\% H}_2 \end{aligned}$$

CURRICULUM VITAE

Name Miss Nuntida Wiset

Date of Birth 18 July 1988

Address 22 Moo 4, Kantharalak, Srisaket, 33110, Thailand

Education

2007-2010 B.Sc. (Chemistry), Khon Kaen University, Thailand

2010-present M.Sc. Program in Chemistry, Suranaree University of
Technology, Thailand
