เบญจลักษณ์ นราไชย : การดูดซับกรดโอเลอิกโดยใช้ตัวดูดซับที่ทำจากแกลบข้าว
(ADSORPTION OF OLEIC ACID USING ADSORBENTS DERIVED FROM RICE
HUSK) อาจารย์ที่ปรึกษา : ผู้ช่วยศาสตราจารย์ ดร.สัตยชัย ประยูร โภคราช, 94 หน้า

กรดไขมันอิสระ (FFA) ในน้ำมันพืชที่กินได้และกินไม่ได้ที่ใช้สำหรับผลิตน้ำมันไบโอดีเซลสามารถทำปฏิกิริยากับตัวเร่งปฏิกิริยาเบส เป็นสาเหตุทำให้ผลได้น้ำมันไบโอดีเซลลดลง และตัวเร่งปฏิกิริยาเสื่อมสภาพ เพื่อช่วยลดปัญหาการควบคุมความเข้มข้นของกรดไขมันอิสระให้ต่ำกว่า 1-2% โดยน้ำหนัก ดังนั้นการวิจัยนี้ จึงสนใจการแยกกรดไขมันอิสระในน้ำมันพืช โดยใช้ตัวดูดซับที่ทำจากชิลิกาจากแกลบข้าว และใช้กรดโอเลอิกเป็นตัวแทนของกรดไขมันอิสระ ตัวดูดซับคือ ชิลิกา, มอร์ดีไนต์ (MOR), MCM-41 ที่ไม่เผา [MCM-41 (A)] และ MCM-41 ที่เผา [MCM-41(C)] การทดลองการดูดซับทำแบบแบดซ์ โดยใช้น้ำหนักตัวดูดซับคงที่ 0.25 กรัม ส่วนความเข้มข้นของกรด เวลา และอุณหภูมิที่ใช้ในการดูดซับแปรเปลี่ยนอยู่ในช่วง 0-3.00%, 0-3 ชั่วโมง และ 25-50 องศาเซลเซียสตามลำดับ

ค่าความจุการดูดซับที่สมดุลที่อุณหภูมิ 25 องศาเซลเซียสของ MCM-41 (A) และ MCM-41 (C) มีค่า 277.8 มิลลิกรัมต่อกรัม และ 270.3 มิลลิกรัมต่อกรัม ตามลำดับ ค่าความจุการดูดซับของ MCM-41 (A) และ MCM-41 (C) มีค่ามากกว่ามอร์ดีไนต์ และชิลิกาประมาณ 4 เท่า การดูดซับกรดโอเลอิกบน MCM-41 (A) และ MCM-41 (C) เป็นไปตามแบบจำลองไอโซเทอร์มแบบแลงเมียร์ สำหรับ MCM-41 (A) มีค่าการเปลี่ยนแปลงเอนทัลปี (ΔH) และการเปลี่ยนแปลงเอนโทรปี (ΔS) เท่ากับ -3.59 กิโลจูลต่อโมล และ 21.5 จูลต่อโมล ตามลำดับ และสำหรับ MCM-41 (C) มีค่าเท่ากับ -7.22 กิโลจูลต่อโมล และ 9.07 จูลต่อโมล ตามลำดับ โดยค่าการเปลี่ยนแปลงพลังงานอิสระกิบส์สำหรับกระบวนการดูดซับของตัวดูดซับทั้งสองนี้มีค่าเป็นลบที่ทุกอุณหภูมิการทดลอง

การใช้ MCM-41 (A) และ MCM-41 (C) ในการดูดซับกรดโอเลอิกในน้ำมันถั่วเหลือง แสดงให้เห็นว่าค่าความจุการดูดซับของ MCM-41 (A) มีค่าเท่ากับ 178.7 มิลลิกรัมต่อกรัม ในสารละลายกรดโอเลอิก 1% ในน้ำมันถั่วเหลือง ในขณะที่ไม่สังเกตพบการดูดซับดังกล่าวเมื่อใช้ MCM-41 (C)

FREE FATTY ACID, ADSORPTION, MCM-41, OLEIC ACID, RICE HUSK
SILICA

Free fatty acids (FFA) in edible and non-edible oils used for the production of biodiesel can react with a basic catalyst and consequently, cause a lower biodiesel yield and catalyst deactivation. To reduce the problems, the concentration of FFA in the oil should be lower than 1-2 wt%. Therefore, in this research removal of FFA in the oils using adsorbents derived from rice husk silica was studied. Oleic acid was used as a representative of FFA. The adsorbents were rice husk silica, mordenite (MOR), noncalcined MCM-41 [MCM-41 (A)] and calcined MCM-41 [MCM-41 (C)]. Adsorption experiments were performed in a batch mode using a fixed weight of the adsorbent, 0.25 g. The concentration of the acid, the adsorption time and the adsorption temperature were varied within the range of 0-3.0%, 0-3 h and 25-50 °C, respectively.

The equilibrium adsorption capacities at 25 °C of MCM-41 (A) and MCM-41 (C) were 277.8 mg/g and 270.3 mg/g, respectively. The adsorption capacities of MCM-41 (A) and MCM-41 (C) are about 4 times larger than those of mordenite and

rice husk silica. The adsorption of oleic acid onto MCM-41 (A) and MCM-41 (C) followed the Langmuir isotherm model. For MCM-41 (A), the enthalpy change (ΔH) and the entropy change (ΔS) were -3.59 kJ/mol and 21.5 J/mol, respectively, and those for the MCM-41 (C) were -7.22 kJ/mol and 9.07 J/mol, respectively. The values of the Gibbs free energy change (ΔG) for the adsorption process of both adsorbents were negative at all studied temperatures.

The application of MCM-41 (A) and MCM-41 (C) in the adsorption of oleic acid in soybean oil showed that the adsorption capacity of MCM-41 (A) was 178.7 mg/g in a solution of 1% oleic acid in soybean oil; whereas, no adsorption was observed using MCM-41 (C).

ACKNOWLEDGEMENTS

I would like to thank everybody who helped me throughout my studies. First of all, I would like to express my sincere gratitude to my advisor, Asst. Prof. Dr. Sanchai Prayoonpokarach, for sharing me his knowledge, supporting me in terms of finance, guiding me and editing my thesis. I also would like to thank the thesis examining committee, including Assoc. Prof. Dr. Jatuporn Wittayakun, Asst. Prof. Dr. Kunwadee Rangsriwatananon and Asst. Prof. Dr. Thanaporn Manyum for their helpful and valuable comments and suggestion during my thesis defense. I would also like to thank all lecturers at the School of Chemistry, Suranaree University of Technology for their good attitude and advice.

I would like to thank the staff of the scientific equipment center of F1, F2 and F10, Suranaree University of Technology for assisting me with the equipment and glassware. I also thank Suranaree University of Technology for the one research one graduate (OROG) scholarship.

Finally, I would like to express my deepest gratitude to my parent and my sisters for their unconditional love and continual encouragement during my education.

Benjaluck Narachai

CHAPTER I

INTRODUCTION

1.1 Introduction

Vegetable oils from many plants such as soybean, palm and jatropha have been used as reactants for the production of biodiesel. The extracted crude oil from the plants is a mixture of many compounds, including free fatty acids (FFA) (Bhosle and Subramanian, 2005). In transesterification using a basic catalyst, FFA content in the oil should not exceed 1 wt%, because the FFA will react with the catalyst to form soap (Demirbaş, 2003; Zhang et al., 2010). The reaction will reduce the amount of the catalyst and the formation of soap will cause a difficulty in separation of biodiesel from the reaction mixture; consequently, these will lower the biodiesel yield. Therefore, it is important to remove or reduce the FFA in the oil. Besides causing the problem in biodiesel production, the presence of FFA in edible oils is also a problem in food, due to their effects on food spoilage and off flavor (rancidity) (Keurentjes, Doornbusch and Van't riet, 1991). Consequently, the removal of FFA will improve the oil quality to be used in the food industry. In this research, adsorption of FFA using adsorbents derived from rice husk silica (RHS) was investigated.

1.2 Adsorption

Adsorption is a phenomenon that results in the accumulation of molecules on a surface of a solid and a structure of the solid is not changed. The solid that accumulates other compounds on its surface is called adsorbent and the compound adsorbed on the adsorbent surface is called adsorbate. Adsorption involves a physical or chemical process. In physical adsorption, no chemical bonds are formed and the adsorption between the adsorbate and the adsorbent occurs from weak intermolecular forces. Chemical adsorption on the other hand, the adsorbate chemically bonds with the adsorbent surface. The amount adsorbed depends on the physical and chemical nature of the adsorbent. Porous solids are usually used in an adsorption process because high surface area or high pore volume increases the chance for the adsorbent and the adsorbate to come into contact and consequently, lead to high adsorption capacity.

The adsorption is based on three mechanisms which are steric, equilibrium and kinetic mechanisms. In the steric mechanism, the adsorbent has pore dimension that restricts to the molecules with certain size or shape. The equilibrium mechanism depends on the different ability of the molecules accumulate on the surface of the adsorbent. The kinetic mechanism is based on the rate of diffusion of molecules into the pore, which is controlled by the time of exposure on active sites (Do, 1998a).

1.2.1 Adsorption at the liquid-solid interface

Adsorption equilibrium will be achieved when the rate of adsorption is equal to the rate of desorption of the adsorbate from the surface of the adsorbent. The amount of the adsorbate bound to the adsorbent is usually measured at a constant temperature. A relationship of the binding of the adsorbate to the adsorbent at a constant temperature

is generally expressed as a curve called an adsorption isotherm. Langmuir and Freundlich isotherm equations are commonly used to describe the adsorption behavior (Demirbas, Sari and Isildak, 2006).

1.2.1.1 Langmuir isotherm

The Langmuir isotherm is used to describe equilibrium adsorption based on three major assumptions (Do, 1998b), which are:

1. the surface of the adsorbent is homogenous; therefore, adsorption energy is constant for all sites,
2. only one molecule or atom can be adsorbed on any one site and adsorption cannot occur beyond a monolayer and
3. there is no interaction between any of the adsorbed molecules or atoms.

The Langmuir adsorption equation can be represented as equation [1];

$$\frac{q}{q_m} = \frac{K_A X_e}{1 + K_A X_e} \quad [1]$$

where, q (mg/g) is the amount of the adsorbate adsorbed per gram of the adsorbent; q_m (mg/g) is the amount of the adsorbate adsorbed to form a monolayer coverage; K_A (L/mg) is the Langmuir adsorption equilibrium constant; X_e (mg/L) is the amount of the adsorbate in a solution at equilibrium.

Adsorption data can be fitted to the Langmuir isotherm in its linear form as equation [2];

$$\frac{X_e}{q} = \frac{X_e}{q_m} + \frac{1}{K_A q_m} \quad [2]$$

The suitability of the adsorbent to the adsorbate can be evaluated by using the Langmuir constant to calculate a value known as the constant separation factor, R_L as shown in equation [3];

$$R_L = \frac{1}{1 + K_A X_0} \quad [3]$$

where, X_0 (mg/L) is the initial amount of adsorbate in a solution.

The value of R_L can be used to indicate the adsorption situations to be unfavorable ($R_L > 1.0$), linear ($R_L = 1.0$), irreversible ($R_L = 0$) and favorable ($0 < R_L < 1.0$) (Hall et al. 1966).

1.2.1.2 Freundlich isotherm

The Freundlich isotherm is another commonly used model. It has a general form as expressed by equation [4];

$$q = K_F X_e^{1/n} \quad [4]$$

where q and X_e are the same as described in equation [1], K_F is the Freundlich constant, indicative of the relative adsorption capacity of the adsorbent and $1/n$ is an empirical constant.

By taking logarithm of equation [4], a linear form of Freundlich isotherm is shown in equation [5];

$$\ln q = \ln K_F + \frac{1}{n} \ln X_e \quad [5]$$

When $\ln q$ is plotted against $\ln X_e$ and the data are treated by linear regression analysis, K_F and $1/n$ can be calculated from the intercept and a slope of the line, respectively. Freundlich model applies well to solid with heterogeneous surface properties.

1.2.2 Thermodynamic study

Thermodynamic parameters including Gibbs free energy change (ΔG), enthalpy change (ΔH) and entropy change (ΔS) are useful in providing the information about the adsorption process. Relationship among a distribution coefficient (K_D), ΔH and ΔS can be described by equation [6];

$$\ln K_D = \frac{\Delta S}{R} - \frac{\Delta H}{RT} \quad [6]$$

where, R is the universal gas constant, ($8.314 \text{ Jmol}^{-1} \text{ K}^{-1}$); and T is the absolute temperature (Kelvin) and K_D can be calculated from equation [7];

$$K_D = \frac{q}{C_f} \quad [7]$$

With q described by equation [8];

$$q = \frac{V(C_i - C_f)}{m} \quad [8]$$

where C_i and C_f are the initial and equilibrium concentrations of the solute (mg/L) respectively, V is the volume of the solution (L) and m is the adsorbent mass (g).

The values of ΔH and ΔS can be calculated from the slope and the intercept of van't Hoff plot of $\ln K_D$ against $1/T$.

The Gibbs free energy change, ΔG , provides information about the process spontaneity, which can be related to ΔH and ΔS as shown in equation [9];

$$\Delta G = \Delta H - T\Delta S \quad [9]$$

The Gibbs free energy change can also be determined using the relation as follows: $\Delta G = -RT \ln K_D$ [10]

The effects of the enthalpy change, entropy change and temperature on spontaneity of a reaction are summarized in Table 1.1.

Table 1.1 The contribution of the enthalpy, entropy, Gibbs free energy change and temperature on spontaneity of a reaction (Zumdahl, S. S. and Zumdahl, S. A., 2007).

ΔH	ΔS	ΔG	Spontaneity of a process
-	+	-	Spontaneous at all temperature
+	-	+	Non-spontaneous
+	+	-	Spontaneous only at high temperature
-	-	-	Spontaneous only at low temperature

1.3 Adsorbents

The adsorbent is an important variable in the adsorption process. The success of the process relies on the adsorbent performance in both equilibrium and kinetics. Porous solids with small particle sizes and a reasonable porosity could be the good adsorbents, as they could provide high adsorption capacity and aid the fast kinetics. The pore size of porous solids was classified by the International Union of Pure and Applied Chemistry (IUPAC) based on the average pore size as shown in Table 1.2.

Table 1.2 IUPAC pore classification.

Type of pores	Mean pore diameter (Å)
Micropore	< 20
Mesopore	20 - 500
Macropore	> 500

1.3.1 Rice husk silica (RHS)

Silicon dioxide (SiO_2) or silica has a structure of silicon atom tetrahedrally bonded to four oxygen atoms and each oxygen atom is shared with other silicon atom. Silica has relatively high thermal and chemical stability. A number of different crystalline forms such as quartz and cristobalite are present in addition to an amorphous form.

Silica can be produced from rice husk and its application in adsorption has been reported by many researchers. Acid leaching by hydrochloric acid and sulfuric acid has been used to recover silica from rice husk (Yalçin and Sevinç, 2001). In this method, rice husk was treated with the acid, washed with water, dried and calcined at 600 °C. A method based on alkaline extraction was also studied (Kalapathy, Proctor and Shultz, 2002). Rice husk was boiled in a sodium hydroxide solution to dissolve the silica out. The solution was separated from the husk and hydrochloric acid was added in to the solution to precipitate the silica.

The surface of silica has silanol groups (Si-OH) which are responsible for its reactivity. The surface can be organically modified to alter the polarity for a certain application.

1.3.2 Mordenite (MOR)

Zeolite is a microporous crystalline aluminosilicate compound consisted of tetrahedral SiO_4 and AlO_4 unit in a framework. At locations where Si^{4+} is substituted by Al^{3+} , the framework carries a negative charge. The negative charge sites are balanced by cations, usually alkali and alkaline earth metals. The arrangement of three-dimensional framework structure leads to the formation of uniform pores. Typically, the pore diameters are between 3 and 10 Å. The cation exchange capability and the open

cavity of the zeolites have contributed to many applications such as a molecular sieve and an adsorbent for saturated and unsaturated hydrocarbons (Pantu, Boekfa and Limtrakul, 2007).

MOR is one of the high silica zeolites. It has two channel sizes, $6.7 \text{ \AA} \times 7.0 \text{ \AA}$ and $2.6 \text{ \AA} \times 5.7 \text{ \AA}$, which are not interconnected. The former channel is formed by 12 tetrahedral units (SiO_4) and the latter is generated from 8 tetrahedra (SiO_4 and AlO_4); therefore, the channels are called 12- and 8-membered ring channels, respectively.

MOR has been used as a catalyst in many petrochemical processes and an adsorbent for adsorption. Pantu et al. (2007) used MOR to adsorb saturated and unsaturated hydrocarbons. The adsorption was due to the acid sites of the zeolite, the van der Waals interaction and the different pore sizes of the zeolite. Sato, Kudo and Tsuda (2011) used MOR to remove radioactive contaminants such as cesium, strontium and barium ions in drinking water. The mechanism responsible for the removal is ion exchange between zeolite counter cations and these contaminants.

Kulawong, Prayoonpokarach, Neramittagapong and Wittayakun (2011) synthesized MOR in sodium form (NaMOR) by mixing a solution of RHS in sodium hydroxide and a solution of sodium aluminate. The mixture in a polypropylene bottle was stirred at room temperature for one day or until the RHS was dissolved completely. The obtained mixture with an original molar composition of $2.5 \text{ Na}_2\text{O} : \text{Al}_2\text{O}_3 : 22\text{SiO}_2 : 518\text{H}_2\text{O}$ was then transferred to a Teflon-lined stainless steel autoclave for crystallization at $170 \text{ }^\circ\text{C}$ for four days. The solid product was separated, washed thoroughly with deionized water, dried at $80 \text{ }^\circ\text{C}$ overnight and calcined in a muffle

furnace at 500 °C for 3 h. The obtained zeolite was reported to have a surface area of 414 m²/g.

1.3.3 MCM-41

MCM-41 is a mesoporous material consisted of silica framework with hexagonal array of cylindrical pores whose dimensions are in the range of 15 Å to greater than 100 Å and the surface area is above 700 m²/g (Beck et al., 1992). MCM-41 possesses a hydrophobic property (Serrano, Calleja, Botas and Gutierrez, 2004) which is particularly useful for the separation of organic compounds or nonpolar substances. Its structural and chemical characteristics make the material properties beneficial for adsorption (Grün, Unger, Matsumoto and Tsutsumi, 1999) and separation technologies (Grün, Kurganov, Schacht, Schiith and Unger, 1996).

MCM-41 is used in many applications such as a support for catalysts (Grün et al., 1999) and an adsorbent for various gases and volatile organic compounds (VOCs) (Hu, Qiao, Zhao and Lu, 2001). In addition, the surfactant contained MCM-41 has been used for removal of nonionic organic compounds such as benzene, toluene and phenol from contaminated wastewater (Ghiaci, Abbaspur, Kai and Seyedeyn-Azad, 2004).

MCM-41 can be produced from RHS and the synthesized condition has been reported (Rintramee, Föttinger, Rupprechter and Wittayakun, 2012). A silicate solution obtained from RHS dissolved in a sodium hydroxide solution was mixed at room temperature with a solution of cetyltrimethyl ammonium bromide (CTAB) used as a template. The pH of the mixture was adjusted to 11 using 2.5 M sulfuric acid (H₂SO₄) and it was stirred for 4 h in a polypropylene bottle. The mixture was transferred to a Teflon-lined stainless steel autoclave and heated at 100 °C for three days. The solid

product was separated, washed thoroughly with deionized water, dried at 100 °C for 24 h and calcined in a muffle furnace at 540 °C for 6 h.

The formation of MCM-41 structure can be explained by two mechanistic pathways. In the first pathway, the surfactant molecules form micelles and then the siliceous framework polycondenses around the micelles. This process is called liquid crystal initiated pathway. In the second pathway, the anionic siliceous associates with the surfactant and then polycondenses to form the MCM-41 structure. This mechanism is called anion-initiated pathway. Calcination of the final product removes the surfactant template to create a mesoporous material with a highly ordered array of pores of well-defined size.

In this research adsorbents derived from rice husk, which are RHS, MOR and MCM-41, were synthesized, characterized, and studied for their capability to adsorb oleic acid. Parameters such as acid concentration, time and temperature that could influence the adsorption efficiency were investigated.

CHAPTER II

LITERATURE REVIEWS

2.1 Introduction

Free fatty acids (FFA) in vegetable oils are classified according to their degree of saturation. The types of FFA are saturated acids whose molecules contain only single carbon-to-carbon bond, such as palmitic acid and stearic acid and unsaturated acids whose molecules have one or more carbon-to-carbon double bonds, such as linoleic acid, oleic acid and linolenic acid. FFA in the vegetable oils can be derived from triglycerides which compose of different fatty acids moiety dependent on their origins. Fatty acid compositions of some vegetable oils are summarized in Table 2.1.

Table 2.1 Fatty acid compositions (%wt) of some vegetable oils (Demirbaş, 2003).

Oil	Palmitic C16:0 ^a	Palmitoleic C16:1	Stearic C18:0	Oleic C18:1	Linoleic C18:2	Linolenic C18:3	Others
Rape seed	3.5	0	0.9	64.1	22.3	8.2	0
Sunflower seed	6.4	0.1	2.9	17.7	72.9	0	0
Sesame seed	15.2	0	6.8	44.6	30.2	0.2	0
Palm	42.6	0.3	4.4	40.5	10.1	0.2	1.1
Soybean	13.9	0.3	2.1	23.2	56.2	4.3	0
Olive kernel	5.0	0.3	1.6	74.7	17.6	0	0.8

^a A symbol Cn:x represents the molecule of a fatty acid with the number of n carbons and x double bonds.

From Table 2.1 C18 fatty acids are among the most abundant components in the vegetable oils; therefore, in this research, oleic acid was selected as a representative of the FFA for the adsorption study.

In recent years, there are many reports in removal of FFA from vegetable oils. Ramadhas, Jayaraj and Muraleedharan (2005) used esterification process with sulfuric acid as a catalyst to reduce the FFA content of the crude rubber seed oil. The crude rubber seed oil and methanol were mixed with 0.5% v/v of sulfuric acid/ oil at 50 °C for 20-30 min under atmospheric pressure. The amount of FFA was reduced from ~17 % wt to < 2 % wt.

Suppalakpanya, Ratanawilai and Tongurai (2010) performed esterification under a microwave heating technique by mixing crude palm oil and ethanol with 1.0 % wt of sulfuric acid/ oil. The mixture was heated at 70 W for 60 min. The FFA content was reduced from ~3-7 % wt to 1.7 % wt. SathyaSelvabala, Varathachary, Selvaraj, Ponnusamy and Subramanian (2010) studied the removal of FFA by using phosphoric acid modified mordenite (PMOR) as a catalyst in esterification of *Azadirachta indica* (Neem) seed oil. Neem seed oil and methanol were mixed with 1 % wt solid catalyst at 60 °C for 3 h. The acid value reduced from 24.4 to 1.8 mg KOH/g oil or 0.90 % wt (%FFA as oleic acid = (mg KOH/g oil)/1.99).

Sathya Selva Bala et al. (2012) used strong acidic ion exchange resins, Amberlite IR 120 and Amberjet 1200 H, as the catalyst in esterification to reduce FFA in *Pongamia Pinnata* (Karanja) oil. The acid value reduced from 12.5 to 1.6 and 1.72 mg KOH/g oil (FFA content of 0.8 and 0.86 w/w) for Amberlite IR 120 H and Amberjet 1200 H catalyzed esterification reaction, respectively. The reaction was conducted with

the catalyst concentration of 1 %wt, the temperature of 60 °C, the methanol to oil ratio of 6:1 and the reaction time of 150 min.

Martins, Ito, Batistella and Maciel (2006) used distillation process for reduction of FFA in vegetable oils. The removal percentage of FFA was 96.16% by using the feed flow rate at 10.4 g of oil/min and the evaporator temperature of 160 °C. The methods of esterification and distillation of FFA are not economical in terms of energy consumption.

Adsorption is another method for FFA removal that has advantages such as simple operating process and low operating cost. Many adsorbents, for example, rice husk ash (RHA) (Saleh and Adam, 1994), silica gel (Atia, El-Nahas, Marie and Mahdy, 2006), RHA and rice husk silica (RHS) (Kim, Yoon, Choi and Gil, 2008), acid treated RHA (Yoon, Kim and Gil, 2011), and mixed bed ion-exchange resins (Jamal and Boulanger, 2010) were used for adsorption of FFA. In this work, adsorbents derived from rice husk silica were used.

Rice husk is an agricultural waste largely generated in rice-producing countries. It contains ~ 25 % wt silica (Yalçin and Sevinç, 2001). Silica extracted from rice husk can be used as a silica source for the production of a number of silica based materials (Khemthong et al., 2007). RHA obtained from pyrolyzed rice husk has been investigated as an adsorbent for FFA (Kim et al., 2008). Silicate films produced from RHA were evaluated for adsorption of FFA in frying oil (Kalapathy and Proctor, 2000). Adsorption of FFA on the silica surface was explained to occur via hydrogen bonding between carboxyl groups of FFA and silanol groups of silica (Atia et al., 2006; Proctor, Adhikari and Blyholder, 1995).

Saleh and Adam (1994) used RHA heated at 480 °C for adsorption of lauric, myristic and stearic acids in isooctane and the adsorption capacities were 35.7 mg/g, 43.5 mg/g and 36.0 mg/g, respectively. The acid adsorption conformed to Langmuir isotherm. Atia and coworkers (2006) studied the adsorption of oleic acid in hexane using silica gel derived from RHA as an adsorbent and explained that the adsorption of oleic acid onto a silica surface occurs via hydrogen bonding between the carboxyl group of the acid and silanol group of the silica surface. The maximum adsorption capacity was 19.7 mg/g at 28 °C. The adsorption data agreed well with Langmuir isotherm. Kim and coworkers (2008) studied the adsorption of FFA in degummed soybean oil using adsorbents obtained from RHA calcined in the temperature range of 300-900 °C and silica gel synthesized using calcined RHA at 500 °C as a silica source. High pyrolysis temperature resulted in the decrease of surface area and pore volume of the RHAs except for RHA pyrolyzed at 500 °C that had the highest pore volume and highest adsorption capacity for FFA. The silica gel and RHA pyrolyzed at 500 °C have similar adsorption capacity. Similar studies were done by Yoon and coworkers (2011). In their studies, RHA was treated with 20 %v/v sulfuric acid and calcined at various temperatures. They found that RHA heated at 500 °C was the most efficient adsorbent among the pyrolyzed RHAs and exhibited no difference in ability in FFA adsorption compared with the acid treated RHA pyrolyzed at 500 °C.

Farook and Ravendran (2000) used RHA that was treated with 1.0 M and 14.0 M nitric acid as the adsorbents for saturated FFAs. RHA treated with 14.0 M nitric acid has higher adsorption capacities than that treated with 1.0 M nitric acid. This was attributed to the increase in specific pore volume. Langmuir isotherm was used to explain the behavior of the adsorption of the acids.

Adam and Chua (2004) studied adsorption of palmitic acid on silica-incorporated aluminium (RHA-Al) and RHA-Al calcined at 500 °C, RHA-Al (C). The maximum adsorption capacities of the RHA-Al were 15.48 mg/g at 30 °C, 15.92 mg/g at 40 °C and 16.64 mg/g at 50 °C. The maximum adsorption capacities of the RHA-Al (C) were 15.82 mg/g at 30 °C, 20.16 mg/g at 40 °C and 21.51 mg/g at 50 °C. The acid adsorption followed Langmuir isotherm. The Al incorporated into the silica matrix acted as Lewis acid responsible for the adsorption by interacting with the C=O of the acid.

From the literatures, it is clear that silica based materials derived from rice husk have been shown to be the potential adsorbents for the removal of FFA. It can also be inferred that the silica based materials with higher surface area than the silica could have higher adsorption capacity for the FFA. Therefore, in this research mordenite and MCM-41 derived from RHS were investigated as the adsorbents for the adsorption of oleic acid.

CHAPTER III

EXPERIMENTAL

3.1 Chemicals

Chemicals used in this research were purchased from various suppliers as shown in Table 3.1. All chemicals were used as received with no further purification.

3.2 Preparation of adsorbents

3.2.1 Rice husk silica

Rice husk silica (RHS) was prepared from the method reported in the literature (Khemthong et al., 2007; Kulawong et al., 2011). Rice husk was washed thoroughly with water to remove adhering soil and dust. After that the rice husk was dried at 100 °C overnight. Dried rice husk, 85 g, was refluxed with 700 mL of 3.0 M HCl in a round-bottomed glass flask at 85 °C for 3 h. After the acid reflux, the color of the rice husk changed from brown to black. The treated rice husk was separated from the solution and washed with water several times until the pH of the filtrate was ~7. The treated rice husk was dried at 100 °C overnight and then calcined in a muffle furnace at 550 °C for 6 h to remove hydrocarbons and volatile compounds. A white powder product was obtained and called rice husk silica. The obtained RHS was ground in a grinder, sieved to the particle sizes of 63-75 μm and kept at room temperature in a desiccator.

Table 3.1 Chemicals used in this work.

Chemicals	% content	Supplier
acetonitrile	99.9	Carlo ERBA
ethyl alcohol	99.9	Carlo ERBA
glacial acetic acid	99.9	J.T.Baker
hexadecyltrimethyl ammonium bromide (CTAB)	99.0	Acros
hydrochloric acid	36.5	Carlo ERBA
isooctane	99.5	Carlo ERBA
isopropyl alcohol	99.5	Carlo ERBA
oleic acid	90.0	Sigma-Aldrich
phenolphthalein	-	QRec
potassium hydrogen phthalate	99.95-100.0	Sigma-Aldrich
potassium hydroxide	85.0	QRec
sodium aluminate	40.0-45.0 Na ₂ O, 50.0-60.0 Al ₂ O ₃	QRec
sodium hydroxide	97.0	Carlo ERBA
sulfuric acid	96.0-98.0	QRec
toluene	99.5	Carlo ERBA

3.2.2 Mordenite

Mordenite (MOR) in sodium form (NaMOR) was synthesized according to the literature (Kulawong et al., 2011). Sodium aluminate, 4.76 g, and 14 mL of 11.3 M NaOH were mixed with stirring provided for 30 min in a polypropylene bottle and 215 mL of deionized water was later added. The mixture was later stirred continuously for another 30 min. After that, 32.7 g of RHS was added and the mixture was stirred at room temperature for 1 day or until the solid was completely dissolved. The clear solution

was transferred to a Teflon-lined stainless steel autoclave with 250 mL capacity for crystallization at 170 °C for 4 days. A solid product obtained was separated by filtration and washed thoroughly with deionized water until the pH of the filtrate was ~7. The solid was dried at 80 °C overnight. The white powder product was ground in a grinder, sieved to the particle sizes of 63-75 µm and kept at room temperature in a desiccator.

3.2.3 MCM-41

Mobil Composition of Matter No.41 (MCM-41) was synthesized using a method from the literature (Rintramee et al., 2012). A 3.0 g of RHS was mixed with 30 mL of 5 M NaOH under stirring in a polypropylene bottle until the RHS was dissolved completely and the solution was added to 90 mL of 0.14 M CTAB solution with stirring provided at room temperature. The solution pH was adjusted to 11-12 by slowly adding 2.5 M H₂SO₄. The solution was transferred to a Teflon-lined stainless steel autoclave with 250 mL capacity and heated at 100 °C for 3 days. The solid product obtained was separated by centrifugation, washed thoroughly with deionized water until the pH of the filtrate was ~7. The obtained solid was dried at 100 °C.

To remove CTAB, the solid product was calcined in a muffle furnace at 540 °C for 6 h and the obtained solid is denoted as MCM-41 (C). For MCM-41 without template removal, it is called MCM-41 (A). Both forms of MCM-41 were ground in a grinder, sieved to the particle sizes of 63-75 µm and kept at room temperature in a desiccator.

3.3 Characterization of the adsorbents

X-ray diffraction (XRD) patterns of the synthesized adsorbents were obtained from a Bruker-AXS D5005 diffractometer to gain the structural information of the adsorbents. A sample of about 0.20 g was irradiated with the X-ray from Cu K_{α} with the source operated at 40 kV and 40 mA. For MCM-41 samples a scan range was 1.5 to 10.0° (2θ) and for silica and MOR the scan range was 5.0 to 50.0° (2θ). A scan speed of 0.5° per min was used for all adsorbents.

The surface area, pore volumes and pore sizes were determined by nitrogen adsorption-desorption analysis at -196 °C using a Micromeritics ASAP 2010. The sample weights of 0.18-0.20 g were used. MCM-41 (A) was degassed at 250 °C for 2 h (Jabariyan and Zanjanchi, 2012) and MCM-41 (C) was degassed at 300 °C for 4 h (Rintramee et al., 2012). The degassed temperature and time were 300 °C and 12 h for MOR (Kulawong et al., 2011) and silica (Artkla et al., 2008).

The specific surface area (S_{BET}) was calculated by Brunauer-Emmett-Teller (BET) method in the relative adsorption pressure (P/P_0) range from 0.001 to 0.990 for all samples. The total pore volume (V_t) was obtained from the nitrogen amount adsorbed in correspondence of P/P_0 equal to 0.99 and the pore size distributions calculated by Barrett-Joyner-Halenda (BJH) method.

The adsorbents were characterized by FTIR to identify functional groups in the structure. FTIR spectra were recorded before and after oleic acid adsorption on a Bruker IR spectrometer, TENSOR 27. To prepare a sample for an IR measurement, a homogeneous mixture between the adsorbent and potassium bromide (KBr) powder ratio 1:6 was ground in a mortar. Small amount of the ground mixture was transferred into a stainless steel disks set and a hydraulic pressure was applied onto the sample

for 1 min to form a thin and transparent pellet. The pellet was put onto the sample holder of the FTIR spectrometer for the transmittance measurements in the range 400-4000 cm^{-1} with the resolution of 4 cm^{-1} .

^{29}Si MAS NMR spectra of MCM-41 samples were obtained with a Bruker nuclear magnetic resonance spectrometer (AscendTM 500, 500 MHz) equipped with a 4 mm probe (MAS BB/1H/F19/F19) and zirconia rotors. The measurement were performed at an operation field of 11.7 Tesla, a frequency at 99.39 MHz, a pulse duration of 4 μs , a recycle delay of 5.0 s and 12000 scans. The spectra were referenced to kaolin ($\delta = -93.1$ ppm).

3.4 Preparation of solutions

3.4.1 Potassium hydroxide solutions

Potassium hydroxide (KOH) was used for the titration of oleic acid. A stock solution of 0.1 M KOH was prepared by dissolving 1.65 g of KOH in 250 mL of carbon dioxide-free deionized water. A solution of 0.01 M KOH was prepared by the dilution of the 0.1 M KOH solution. The solution was standardized with potassium hydrogen phthalate using 1% phenolphthalein solution as the indicator.

3.4.2 Phenolphthalein indicator

Phenolphthalein was used as an indicator for the titration of KOH and oleic acid. To prepare 1% w/v phenolphthalein, 1.0 g of phenolphthalein was dissolved in 50 mL of ethanol. The solution was transferred into a 100 mL volumetric flask and the volume of the solution was adjusted with carbon dioxide-free deionized water.

3.4.3 Toluene and isopropanol solution

A mixture of toluene and isopropanol with 1:1 volume ratio was used as a solvent for the titration of oleic acid in isooctane and in vegetable oil. Before using in the titration, the solution was neutralized with a standardized 0.1 M KOH using phenolphthalein as the indicator.

3.5 Adsorption studies

Solutions of oleic acid in isooctane with the concentrations in the range of 0.10-3.00 %w/v were used in the adsorption isotherm study. To 25 mL of the oleic acid solution, an adsorbent (predried at 110 °C and cooled) weight of 0.25 g was added. The mixture contained in a 125 mL erlenmeyer flask was placed into a flask clamp mounted on a platform inside a stainless steel water bath. The water bath dimension was 35.5 cm (L) × 45.0 cm (W) × 12.0 cm (H). The water bath was connected to a temperature controlled water bath (Heto Lab Equipment, AT110). Stirring was provided to the adsorption mixture using a multiposition stirrer (DiLigent) for 60 min. After stirring was stopped for 30 s, the adsorbent was separated from the oleic acid solution by gravitation. The clear solution was used for determination of oleic acid by titration with 0.01 M KOH.

Effect of adsorption time on the adsorption capacity was investigated in the time range of 10-180 min. The temperature for the adsorption study was fixed at 25 °C. Solutions of oleic acid in isooctane with the concentration of 0.50 %w/v, the adsorbent weight of 0.50 g were used in the adsorption study.

Influence of temperature on the adsorption was investigated in the temperature range of 25-50 °C. The concentration of oleic acid in isooctane was 0.50 % w/v and the weight of the adsorbent was 0.25 g.

3.6 Determination of oleic acid

3.6.1 Titration

The oleic acid concentration in a solution was determined using the American Oil Chemists' Society method for the determination of free fatty acid (AOCS Ca 5a 40). The volume of oleic acid solution and the solvent mixture of toluene and isopropyl alcohol used in the titration are shown in Table 3.2.

Table 3.2 Volumes of oleic acid solutions used in the titration.

Concentration of oleic acid (% w/v)	Volume of oleic acid (mL)	Volume of toluene/isopropyl solution (mL)
0.10	2.00	25.0
0.50	2.00	25.0
1.00	0.50	25.0
2.00	0.50	25.0
2.50	0.50	50.0
3.00	0.50	50.0

3.6.2 High performance liquid chromatography (HPLC)

High performance liquid chromatography (Agilent 1260 Infinity) equipped with standard autosampler (G1315D) and a diode array detector was used for the determination of oleic acid in the adsorption studies that used MOR as the adsorbent. The method used was modified from the literature (Sanches-Silva et al., 2004).

A reversed phase Hypersil ODS C-18 column (250 mm × 4.0 mm i.d., particle size 5 µm) was used for separation of oleic acid and a mobile phase was acetonitrile mixed with 0.4% acetic acid in H₂O with the ratio 90:10. A mobile phase flow rate was 1 mL/min and the column temperature was controlled at 60 °C. A UV spectrometer was used as a detector and the absorbance of the eluate was measured at 195 nm.

CHAPTER IV

RESULTS AND DISCUSSION

4.1 Characterization of adsorbents

4.1.1 XRD

Silica leached from rice husk was characterized by XRD to confirm the success of the extraction. The XRD pattern in Figure 4.1 shows a broad peak about 22° which is a characteristic of amorphous silica. The extracted silica was subsequently used as a silica source for the synthesis of MOR and MCM-41 and it was also used as the adsorbent.

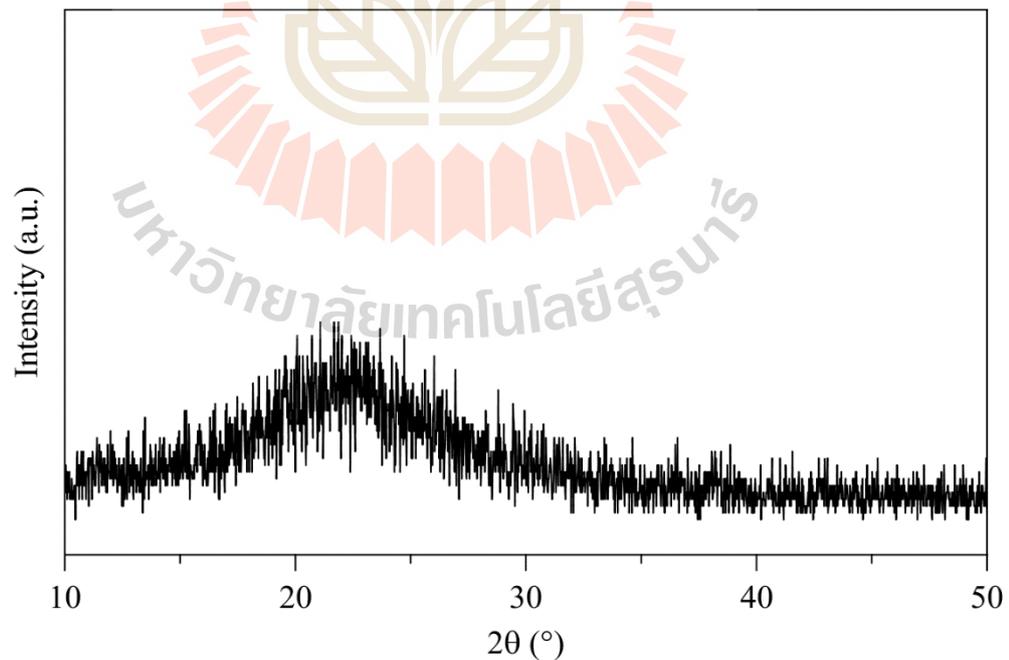

Figure 4.1 XRD pattern of silica.

MOR was successfully synthesized after 96 h of hydrothermal treatment and its XRD pattern is shown in Figure 4.2. All peaks are characteristic of MOR (Kulawong et al., 2011).

The X-ray patterns of the as-synthesized MCM-41 [MCM-41 (A)] and the calcined MCM-41 [MCM-41 (C)] at low angles between 2.50° and 7.00° are shown in Figure 4.3. For MCM-41 (A) characteristic peaks at 2.07° and weak peaks at 3.50° , 4.10° and 5.40° are the reflection of (100), (110), (200) and (210), respectively. The pattern demonstrated the hexagonal arranged channels (Bhagiyalakshmi et al., 2010). A similar pattern was also observed for MCM-41 (C); however, there is a small shift of the diffraction peaks toward higher 2θ . This is due to the lattice shrinkage as a result of the template removal by calcination (Kleitz et al., 2003). It is noted that lower intensity was obtained with MCM-41 (A). This is caused by the template filled in the mesopore structure (Goworek et al., 2007; Kleitz et al., 2001).

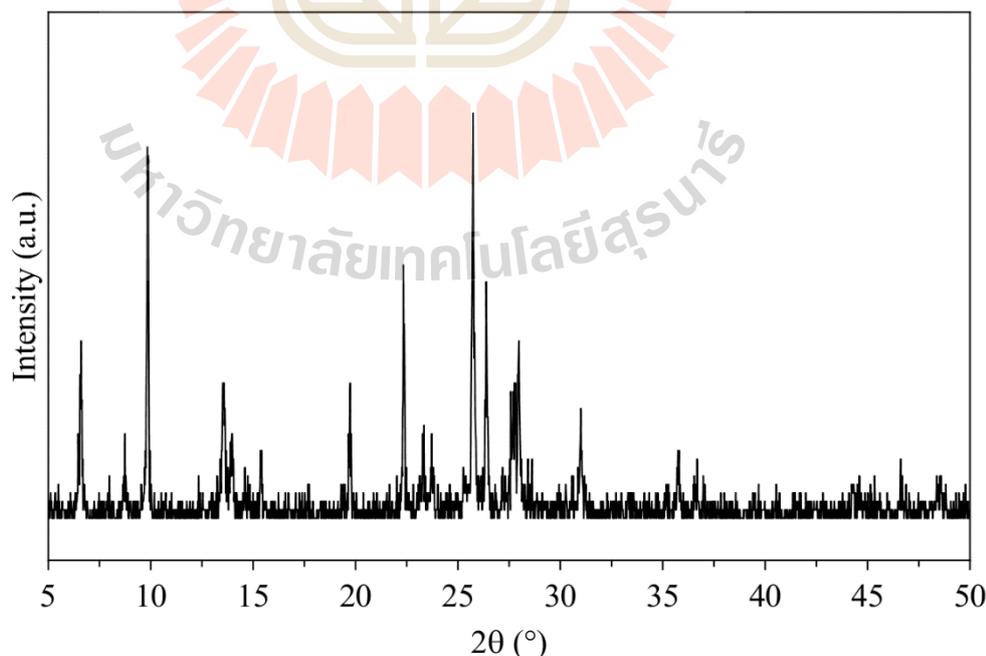

Figure 4.2 XRD pattern of MOR synthesized using rice husk as a silica source.

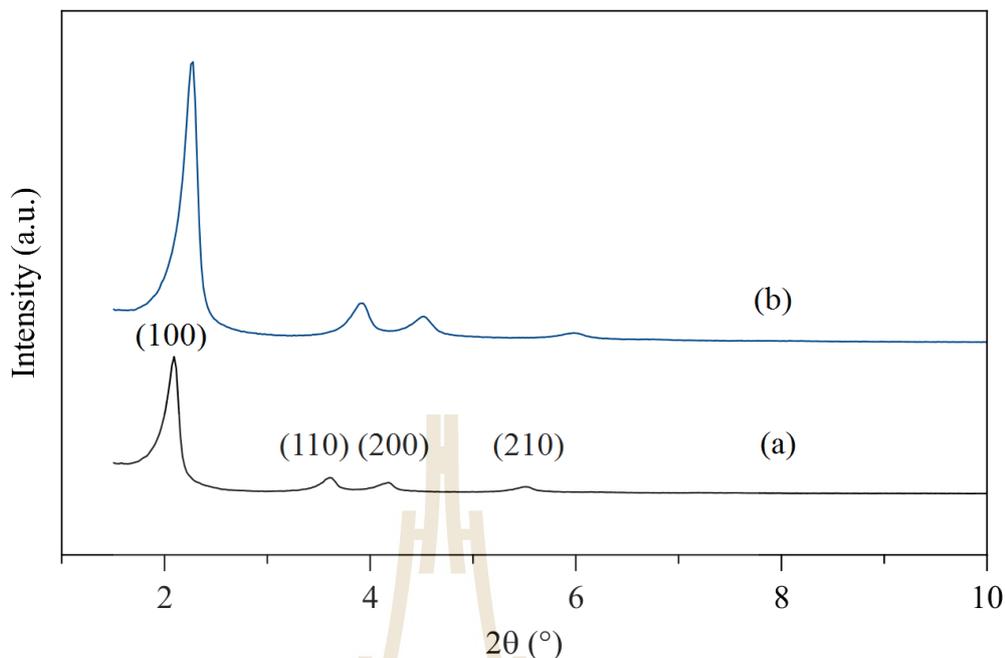

Figure 4.3 XRD patterns of (a) MCM-41 (A) and (b) MCM-41 (C).

4.1.2 Nitrogen adsorption-desorption analysis

The extracted silica from rice husk was subjected to nitrogen adsorption-desorption analysis to obtain its textural properties. Figure 4.4 shows a nitrogen adsorption-desorption isotherm of the silica which is of type IV. The material properties derived from the gas analysis are shown in Table 4.1.

The nitrogen adsorption-desorption isotherm of MOR is shown in Figure 4.5. It is a typical type I isotherm. The amount of adsorbed nitrogen increased rapidly at low relative pressure (P/P_0) and saturation was quickly reached. This is a characteristic of microporous materials. The textural properties of MOR are shown in Table 4.1.

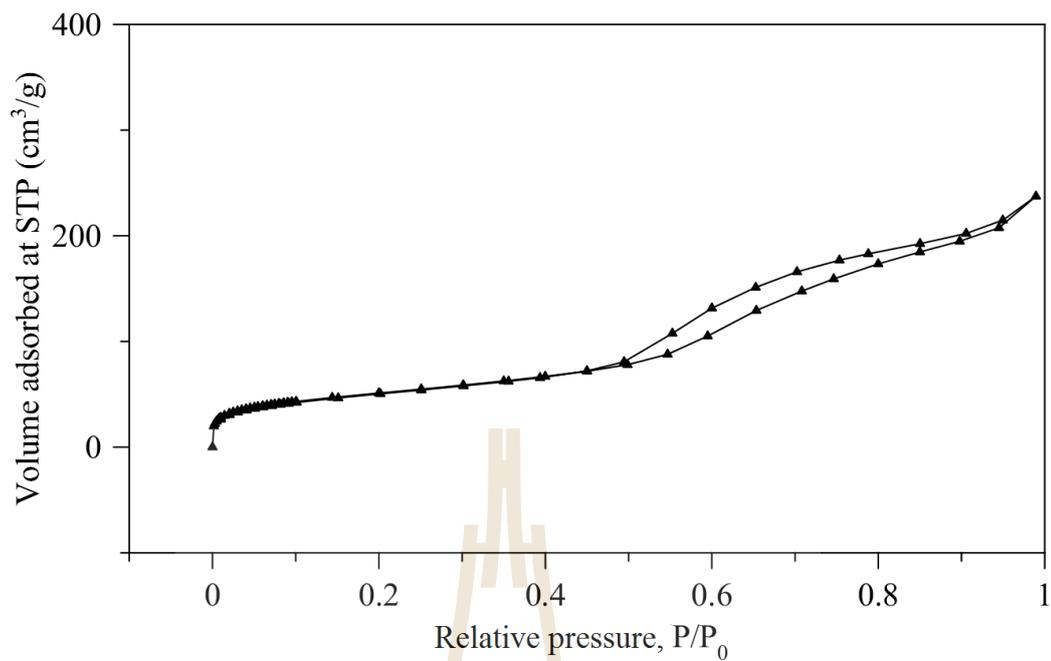

Figure 4.4 Nitrogen adsorption-desorption isotherm of the silica.

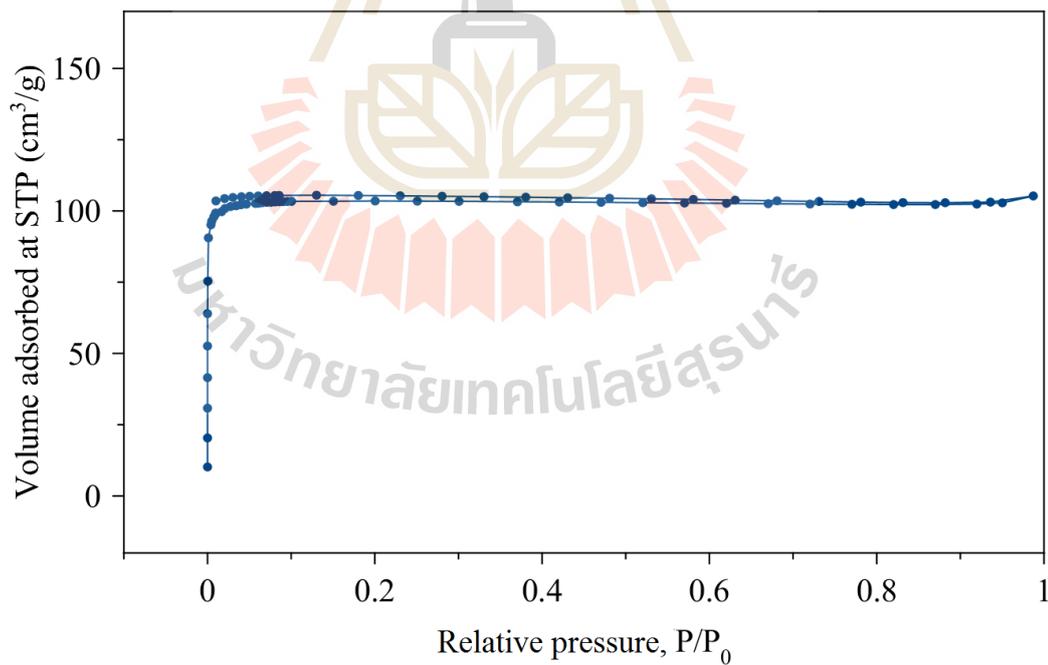

Figure 4.5 Nitrogen adsorption-desorption isotherm of MOR.

The nitrogen adsorption-desorption isotherms of MCM-41 (A) and MCM-41 (C) are shown in Figure 4.6. They are of the typical type IV according to the IUPAC classification. The MCM-41 (A) shows a small hysteresis loop at the P/P_0 range of 0.10-0.30. This could result from the weak interaction between nitrogen and the surfactant (Jaroniec et al., 1998). The values of the surface areas, specific pore volumes and average pore diameters are summarized in Table 4.1. The results show that the surface area and pore volume of MCM-41 (C) were increased after calcination because of the removal of the surfactant template.

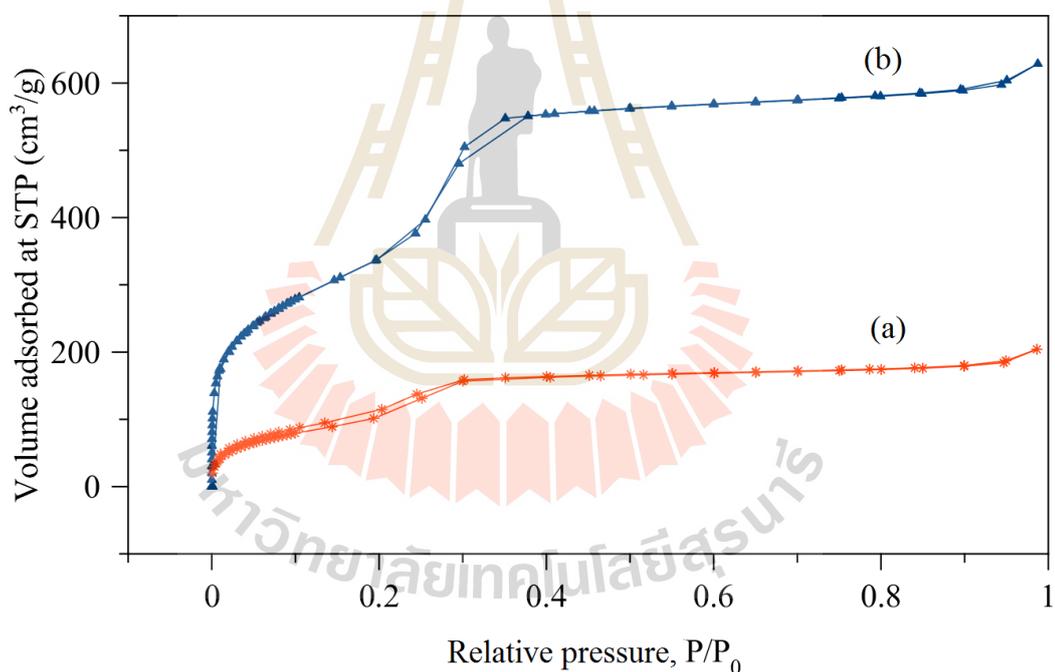

Figure 4.6 Nitrogen adsorption-desorption isotherms of (a) MCM-41 (A) and (b) MCM-41 (C).

Table 4.1 Results from nitrogen adsorption-desorption analysis.

Sample	BET surface area (m ² /g)	Total pore volume (cm ³ /g)	Average pore diameter (Å)
Silica	181	0.367	81
MOR	339	0.159	19
MCM-41 (A)	434	0.316	29
MCM-41 (C)	1288	0.972	30

4.2 Adsorption study

4.2.1 Adsorption of oleic acid on silica, MOR, MCM-41 (A) and MCM-41 (C)

Adsorption of all adsorbents was initially compared by conducting adsorption experiments with various concentrations of oleic acid and a fixed amount of the adsorbents at 0.25 g. The temperature of solutions was controlled at 25 °C. The adsorption time was fixed at 1 h. The results are shown in Figure 4.7. The graph is plotted between the concentration of oleic acid in isoctane, X_e and the mass of oleic acid adsorbed per gram of the adsorbent or adsorption capacity, q_e .

All adsorbents can adsorb oleic acid and the adsorption capacity increases with the increasing of the concentration of oleic acid. The adsorption capacity tends to reach a plateau at high concentration of oleic acid.

Highest adsorption capacity is obtained with MCM-41 (C) and the adsorption capacities of MCM-41 (A) are slightly different from those of MCM-41 (C). High adsorption capacities in MCM-41 adsorbents could be due to the high surface area and the large pore diameter compared to the other adsorbents. The adsorption capacities of MOR and silica are about the same at high concentrations of the acid and about three

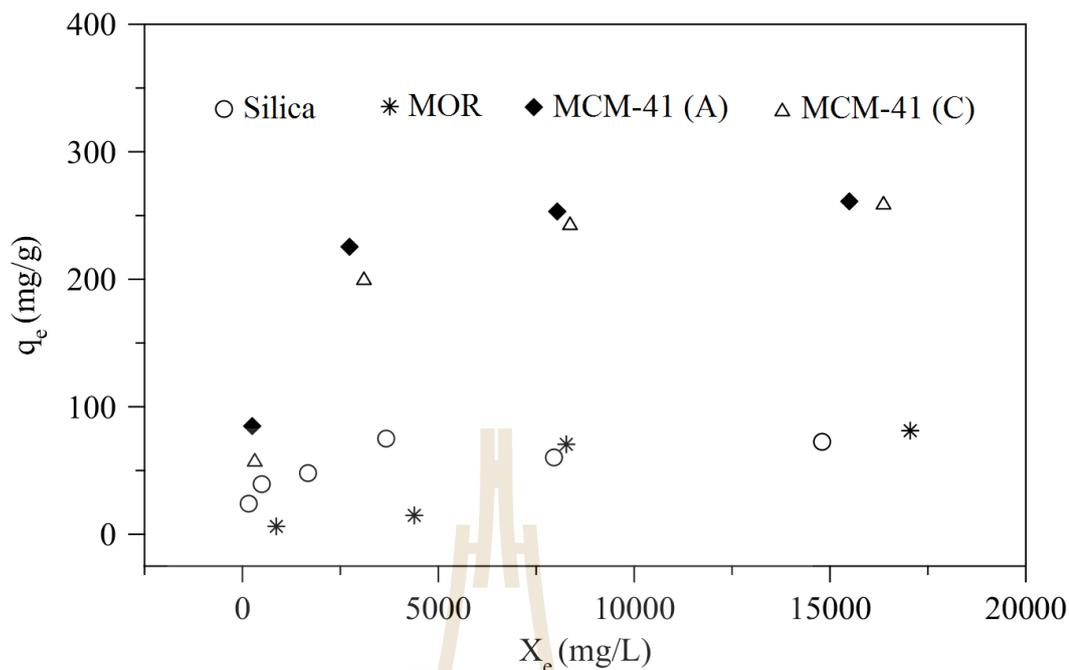

Figure 4.7 The adsorption capacities for oleic acid of silica, MOR and MCM-41 at various concentrations of oleic acid solutions.

times lower than those of the MCM-41 adsorbents. Although MOR has the surface area ~2 times higher than that of silica, silica has larger pore sizes that can accommodate the adsorption.

The adsorption of oleic acid proceeds via hydrogen bonding of the oxygen of the carboxyl group of the acid with the hydrogen of the silanol group. The hydrogen of the carboxyl group of the acid can also form a hydrogen bond with the oxygen of the silanol group (Atia et al., 2006).

The adsorption of oleic acid on the adsorbent surface can be verified through the IR spectroscopy. The IR spectra of the silica and the MOR before adsorption are shown in Figure 4.8 and 4.9, respectively. The bands in the range of 700-1200 cm^{-1} correspond to vibration modes of silica network where asymmetric stretching vibration

of the siloxane bond, Si-O-Si appears at 1109 cm^{-1} (Ahmed and Adam, 2007) and the broad band at $2800\text{-}3750\text{ cm}^{-1}$ is related to OH of the silanol group and water (Kalapathy et al., 2000; Yates et al., 1997). The bending vibration of Si-O-Si occurs at $450\text{-}460\text{ cm}^{-1}$ (Lenza and Vasconcelos, 2001). After the adsorption of oleic acid, the change of the spectrum due to H-bonding of the carboxyl group and the silanol group can be difficult to identify. However, the weak bands occurred at 2868 and 2942 cm^{-1} for silica and 2862 and 2939 cm^{-1} for MOR correspond to C-H stretching of the alkyl chain (Braga et al., 2011) which indicate the presence of oleic acid on the adsorbents.

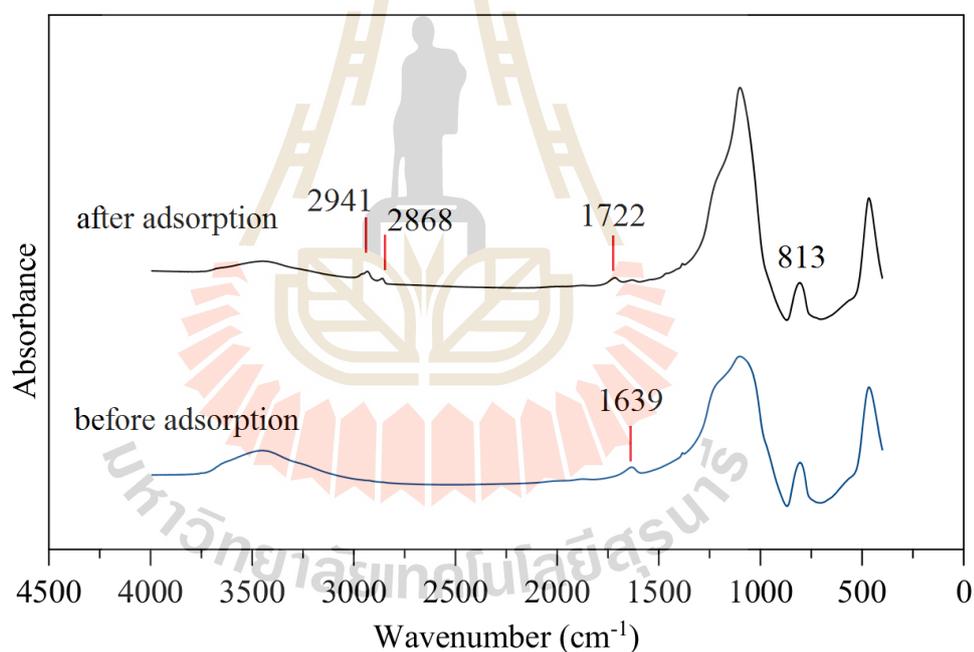

Figure 4.8 IR spectra of silica before and after the adsorption of oleic acid.

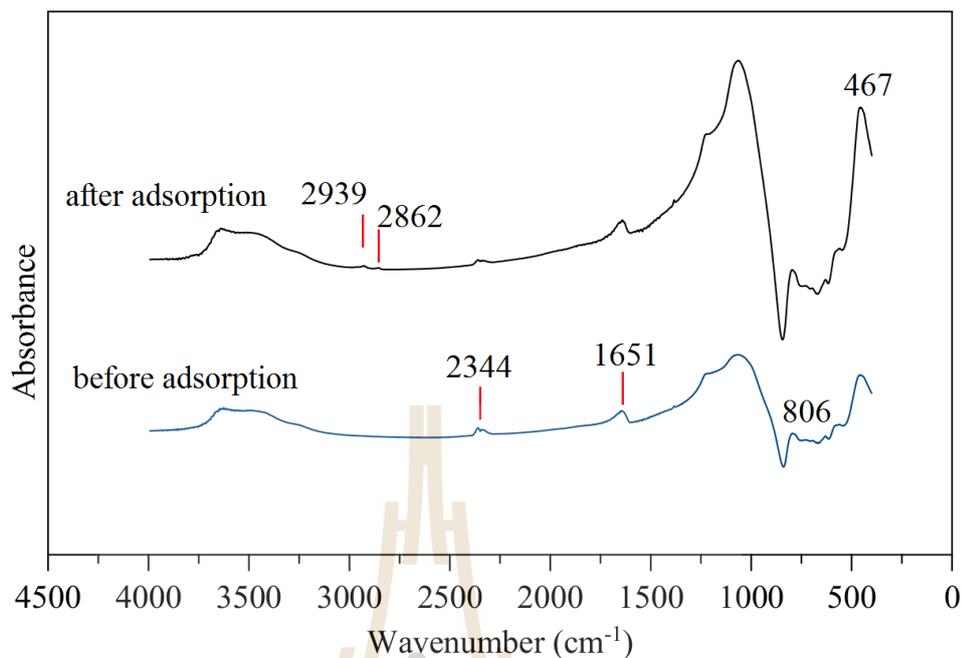

Figure 4.9 IR spectra of MOR before and after the adsorption of oleic acid.

The IR spectra of the MCM-41 (A) before adsorption in Figure 4.10 shows the band related to asymmetric Si-O-Si stretching at 1240 cm^{-1} and 1090 cm^{-1} , Si-O-Si bending vibration at 457 cm^{-1} , free silica at 804 cm^{-1} , C-H stretching modes at 2925 and 2858 cm^{-1} and C-H bending vibrations at $1480\text{-}1590\text{ cm}^{-1}$ that associate with the carbon long-chain template molecules (Braga et al., 2011).

For MCM-41 (A) after the adsorption of oleic acid, a weak band occurs at 1722 cm^{-1} and is assigned to C=O (Morais and Jardim, 2005) suggesting the presence of oleic acid on the adsorbent.

The spectra of MCM-41 (A) and MCM-41 (C) are shown in Figure 4.11. Characteristic bands of the Si-O-Si network are observed as in the silica and MOR. After calcination at $540\text{ }^{\circ}\text{C}$ for 6 h, the bands related to the template molecules clearly disappear and the peak at 1643 cm^{-1} corresponds to vibration of molecular water

which is trapped in the silica framework (Appaturi et al., 2012; Lenza and Vasconcelos, 2001).

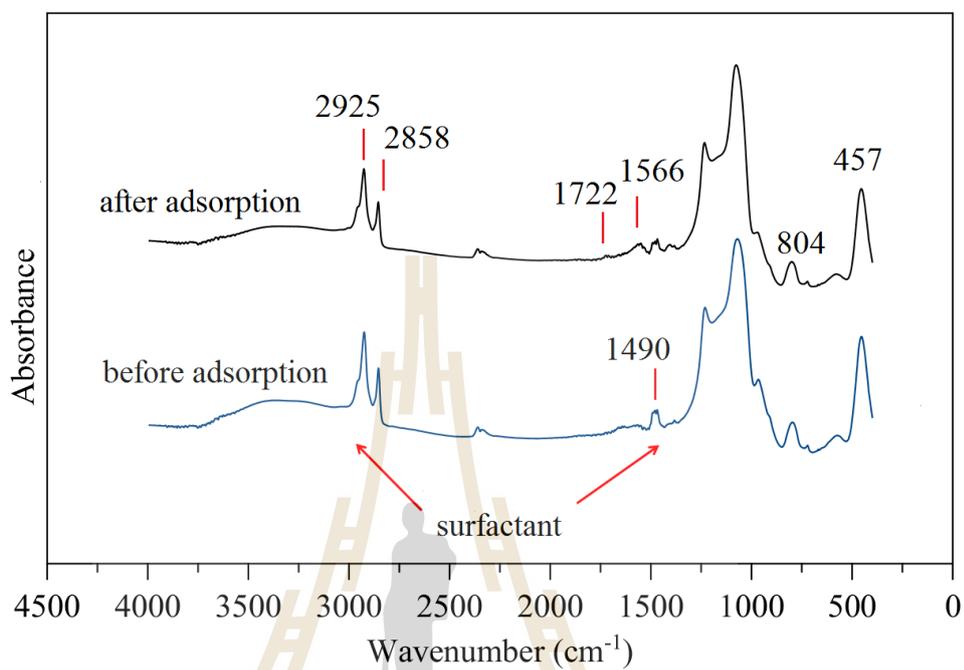

Figure 4.10 IR spectra of MCM-41 (A) before and after the adsorption of oleic acid.

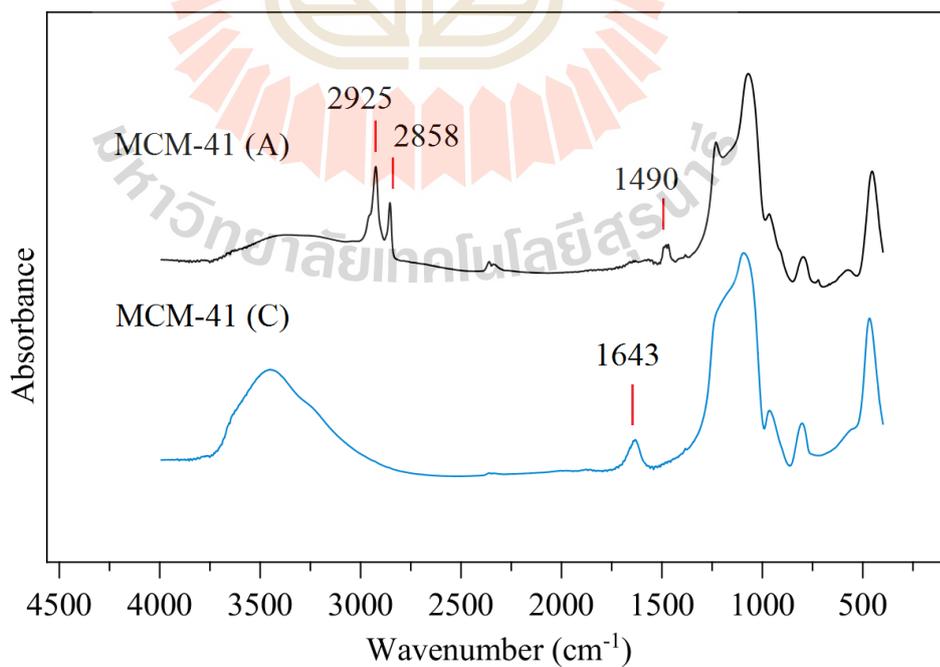

Figure 4.11 IR spectra of MCM-41 (A) and MCM-41 (C).

For MCM-41(C) after the adsorption, two bands appear at 2862 and 2933 cm^{-1} as shown in the Figure 4.12. The band at 2862 cm^{-1} could be assigned to CH_2 asymmetric vibrations and the other at 2933 cm^{-1} to CH_2 symmetric vibrations. The peak at 1710 cm^{-1} could be assigned to $\text{C}=\text{O}$ stretching (Kumar et al., 2002; Lenza and Vasconcelos, 2001).

4.3 Equilibrium adsorption of MCM-41 (A) and MCM-41 (C)

From the adsorption capacity results in Figure 4.7, it is clear that MCM-41 (A) and MCM-41 (C) have relatively high adsorption capacities for oleic acid. Therefore, both adsorbents were used further for the equilibrium adsorption study.

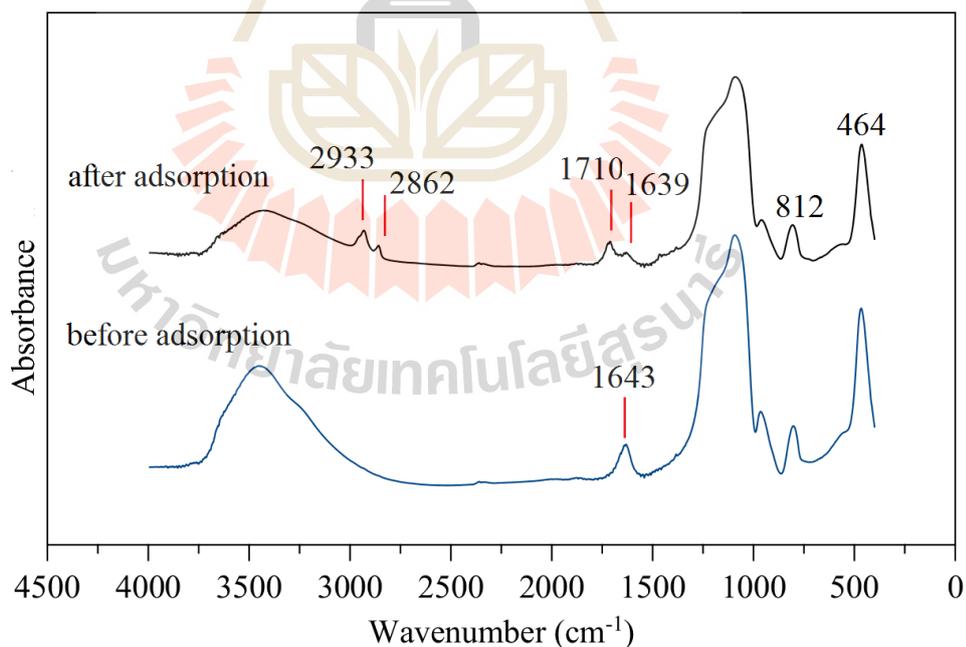

Figure 4.12 IR spectra of MCM-41 (C) before and after the adsorption of oleic acid.

To investigate the time that is used for the adsorption to reach the equilibrium, the adsorption study was carried out in solutions of 0.5% oleic acid with 0.25 g of the adsorbent. The adsorption time was varied in a range of 10-180 min. The temperature was controlled at 25 °C.

MCM-41 (A) adsorbs oleic acid rapidly and the adsorption capacity reaches the equilibrium in about 15 min as shown in Figure 4.13. Adsorption by MCM-41 (C) on the other hand is slower and the equilibrium is reached in 60 min. The MCM-41 (A) can adsorb oleic acid rapidly because the tail of CTAB having a hydrophobic character (Ghiaci et al., 2004) can interact with oleic acid and helps the diffusion of oleic inside the pore of MCM-41 (A). To make sure that the adsorption is at the equilibrium, the adsorption time of 60 min was used in further study.

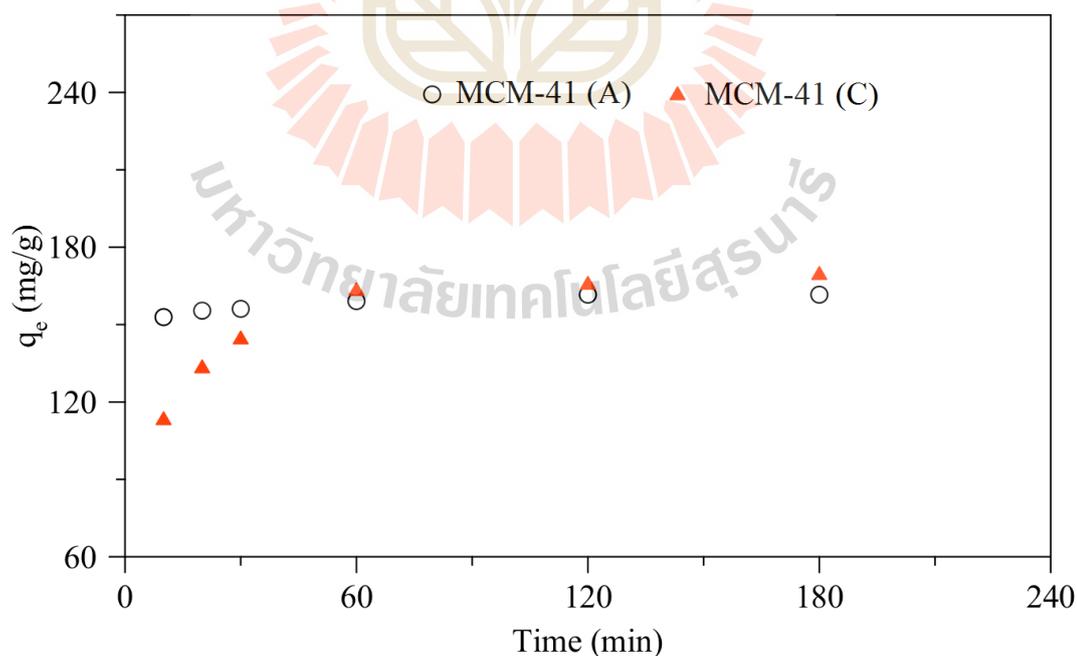

Figure 4.13 Time dependent adsorption for MCM-41 (A) and MCM-41 (C).

It was noted that the adsorption capacities of the MCM-41 (A) and MCM-41 (C) at equilibrium were about the same, ~160 mg/g although the surfactant still remained in the pore of the MCM-41 (A). Therefore, further investigation dealing with the sites of adsorption was conducted using nuclear magnetic resonance spectrometry (NMR).

Adsorption sites of MCM-41 (A) and MCM-41 (C) were investigated using ^{29}Si MAS-NMR spectroscopy. NMR spectra are shown in Figure 4.14 and 4.15. After the deconvolution of the NMR spectra, three peaks were obtained and can be used to calculate parameter such as condensation degree (Shylesh and Singh, 2006), relative proportion of different silicon environments (Costa et al., 2008) and molar percentage of silanol groups (Igarashi et al., 2003).

The chemical shifts of three peaks for both MCM-41 (A) and MCM-41 (C) are shown in Table 4.2. These chemical shifts are assigned to three silicon environments that are Q^2 , two OH groups attach to the same silicon atom; Q^3 , one free hydroxyl attaches to a silicon atom and Q^4 , no OH group associates to the Si atom (Hamdan et al., 1997). Figure 4.16 shows the silicon environments of the aforementioned chemical shifts.

Table 4.2 ^{29}Si chemical shifts of the MCM-41 (A) and MCM-41 (C).

adsorbent	Q^2 (ppm) ; $\text{Si}(\text{OSi})_2(\text{OH})_2$	Q^3 (ppm) ; $\text{Si}(\text{OSi})_3(\text{OH})$	Q^4 (ppm) ; $\text{Si}(\text{OSi})_4$
MCM-41 (A)	-92.0	-102.5	-112.3
MCM-41 (C)	-93.3	-103.0	-111.2

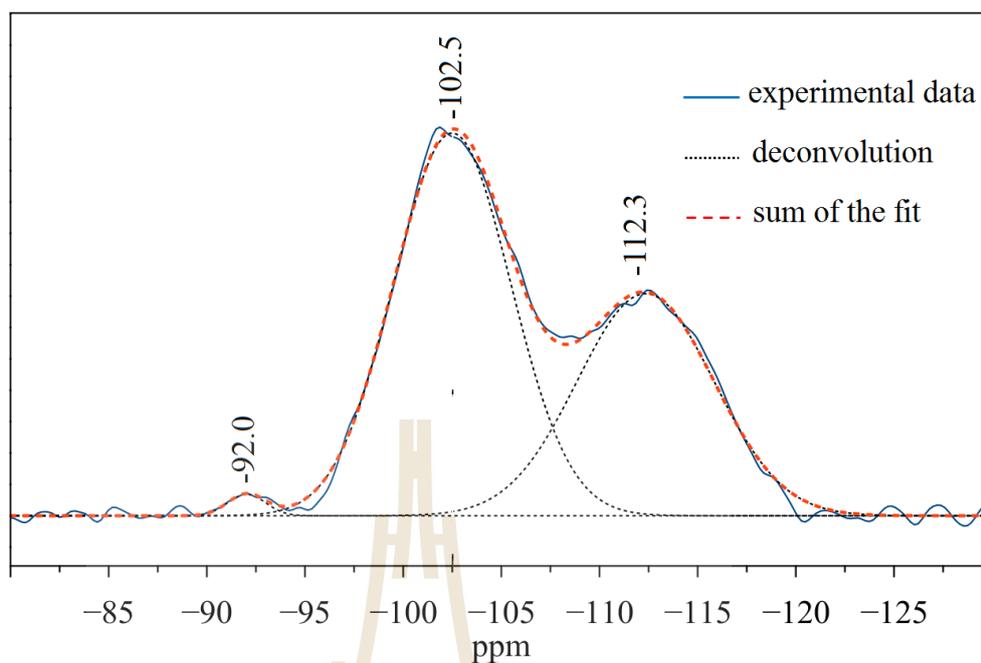

Figure 4.14 ^{29}Si MAS NMR spectrum of MCM-41 (A) and the deconvolution. The correlation coefficient of the fit is 0.9964.

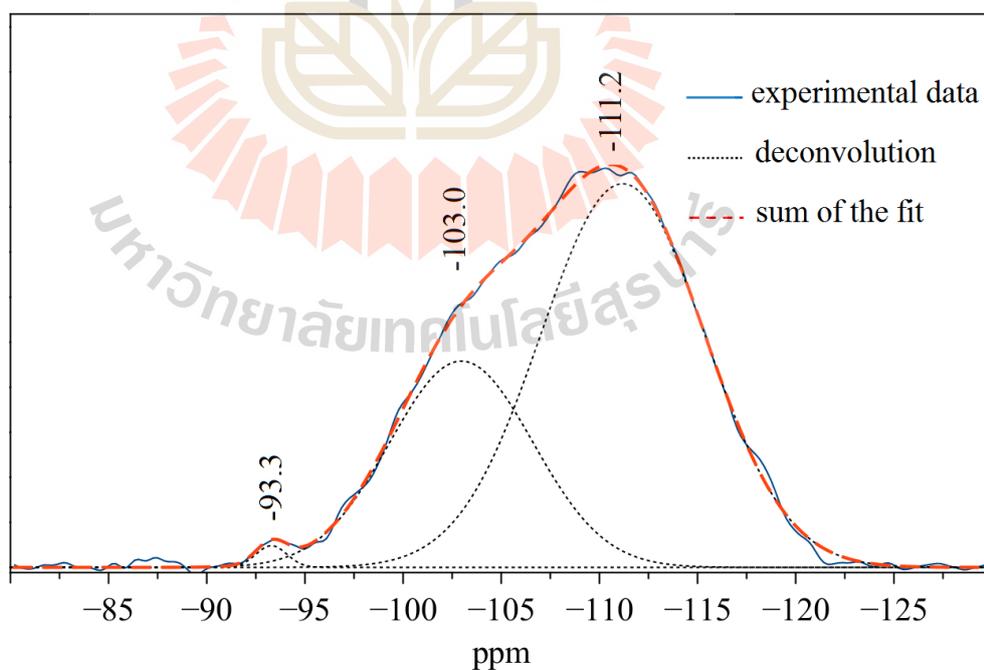

Figure 4.15 ^{29}Si MAS NMR spectrum of MCM-41 (A) and the deconvolution. The correlation coefficient of the fit is 0.9990.

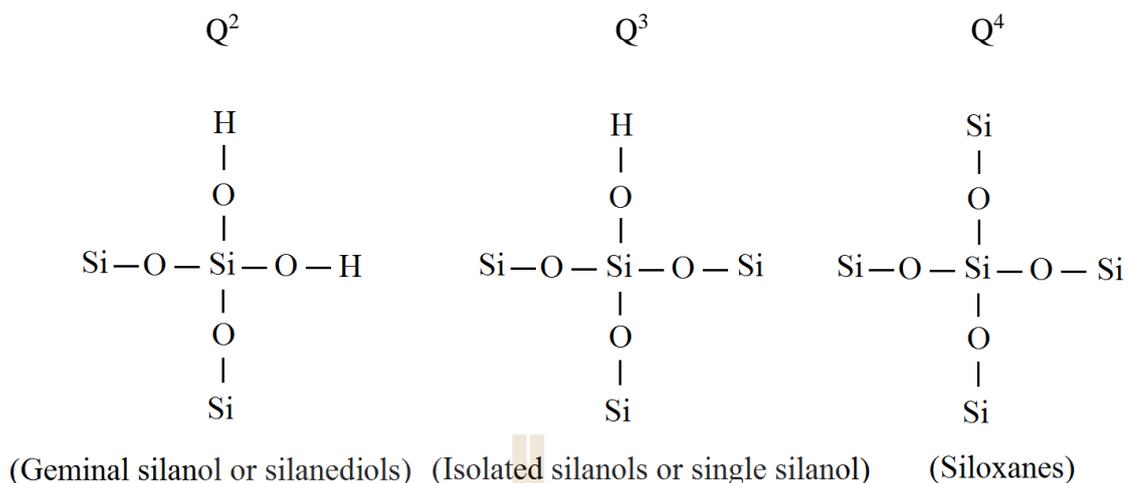

Figure 4.16 Chemical environments of silicon in silica surfaces (Costa et al., 2008; Shylesh and Sing, 2006).

From the deconvolution of the NMR spectra of MCM-41 (A) and MCM-41 (C), percentages of Q^2 , Q^3 and Q^4 are obtained and shown in Table 4.3. When the template molecules were removed by calcination, the percent of Q^4 increased and that of Q^3 slightly decreased. This is due to the condensation of silanol group and the formation of siloxane bridge in the structure (Costa et al., 2008). According to the result in Table 4.3, the thermal treatment caused a slight decrease in the percentage of total silanol groups. This results conform well to the adsorption capacities of both MCM-41 adsorbents that are about the same.

Table 4.3 Relative proportions of the different silicon chemical environments determined by ^{29}Si MAS-NMR.

Adsorbent	Relative proportion of the chemical environment (%)			SiOH (mol %-Si) ^a
	Q ²	Q ³	Q ⁴	
	MCM-41 (A)	1.1	59.0	
MCM-41 (C)	0.7	31.7	67.6	33.1

^aRelative amount of silanol groups = $[(2Q^2 + Q^3) / (Q^2 + Q^3 + Q^4)] \times 100\%$ (Igarashi et al., 2003)

4.4 Isotherm study

An adsorption isotherm describes the relationship between the adsorption capacity and the remaining amount of an adsorbate in a solution and is the method used to evaluate the mechanism of adsorption. The experimental equilibrium data of this study are correlated with the Langmuir and Freundlich model. The data used for fitting with the models were from the adsorption studies using 0.25 g of the adsorbent mixed in a solution of oleic acid which the concentration was within the range of 0.25-3.00%. The adsorption time was fixed at 1 h. The adsorption temperature was varied in a range of 25-50 °C.

4.4.1 MOR

The adsorption data from the study with MOR were fitted with Langmuir and Freundlich model and the results are shown in Table 4.4 and 4.5. MOR has relative low adsorption capacity for oleic acid. For Langmuir model, the data were used for the plot of X_e/q versus X_e . The correlation coefficients (R^2) for every studied temperatures were

less than 0.9 indicating that the adsorption of oleic acid on MOR does not follow Langmuir model.

Table 4.5 shows the Freundlich parameters for oleic acid adsorption onto MOR that can be examined from the plots of $\ln q_e$ versus $\ln X_e$ in the temperature range of 25-40 °C. The correlation coefficients were > 0.9 at 25 and 40 °C and about 0.8 at 30 °C. Although Freundlich model is not the best fitted model for the experimental data, it can be inferred that the adsorption sites are not uniform.

Table 4.4 Langmuir isotherm models, Langmuir constants and other derived parameters for the adsorption of oleic acid onto MOR.

Temperature (°C)	Linear equation ^a	R ²	q _m (mg/g)	K _A (L/mg)
25	y = 0.0011x + 182.9993	0.0024	909.1	6.01 × 10 ⁻⁶
30	y = 0.0144x + 90.7236	0.7458	69.4	1.59 × 10 ⁻⁴
40	y = -0.0036x + 301.1958	0.1193	212.8	-1.20 × 10 ⁻⁵

^a A linear form of Langmuir model is $\frac{X_e}{q} = \frac{X_e}{q_m} + \frac{1}{K_A q_m}$.

Table 4.5 Freundlich isotherm models, Freundlich constants and other derived parameters for the adsorption of oleic acid onto MOR.

Temperature (°C)	Linear equation ^a	R ²	1/n	K _F (mg/g)
25	y = 0.9187x - 4.5035	0.9228	0.0187	1.11 × 10 ⁻²
30	y = 0.4373x - 0.3466	0.7948	0.4373	7.07 × 10 ⁻²
40	y = 1.1775x - 7.0988	0.9189	1.1775	8.00 × 10 ⁻³

^a A linear form of Freundlich model is $\ln q = \ln K_F + \frac{1}{n} \ln X_e$.

4.4.2 MCM-41 adsorbents

The linear form of the Langmuir plot for adsorption of oleic acid onto MCM-41 (A) and MCM-41 (C) can be examined from the plots of X_e/q versus X_e in the temperature range of 25-50 °C. Table 4.6 and 4.7 show the Langmuir isotherm equations and derived parameters. The R^2 value of > 0.99 indicates that the adsorption data of oleic acid onto both MCM-41 adsorbents were fitted well with the Langmuir isotherm within the concentration range used in this experiment.

Comparing q_m values for both adsorbents at the same adsorption temperature, the values are about the same at 25 and 35 °C, but slightly different at 40 and 50 °C. Adsorption capacity for both adsorbents tend to be about the same. This could be due to that the adsorption could take place only about the entrance of the pores. For MCM-41 (C) the adsorbed acid molecules could hinder further adsorption of the acid inside the pores. Whereas for MCM-41 (A), CTAB inside the pores of MCM-41 could block the acid adsorption inside the pores.

The fitted isotherm curves along with the experimental data are shown in Figure 4.17 and 4.18. The experimental data distributed closely to the model line at 25 °C, 30 °C, 40 °C and 50 °C indicating a good agreement of the experimental data and the fitted model. The adsorption of oleic acid onto MCM-41 (A) and MCM-41 (C) is influenced by temperature, that is the adsorption capacity decreases with the increasing temperature. This suggests that the adsorption of oleic acid on MCM-41 adsorbents is an exothermic process.

Table 4.6 Langmuir isotherm equations, Langmuir constants and other derived parameters for the adsorption of oleic acid onto MCM-41 (A).

Temperature (°C)	Linear equation	R ²	q _m (mg/g)	K _A (L/mg)
25	y = 0.0036x + 4.4041	0.9951	277.8	8.17 × 10 ⁻⁴
30	y = 0.0039x + 2.0501	0.9946	256.7	1.90 × 10 ⁻³
40	y = 0.0047x + 2.8752	0.9904	212.8	1.64 × 10 ⁻³
50	y = 0.0050x + 3.1015	0.9860	200.0	1.61 × 10 ⁻³

Table 4.7 Langmuir isotherm equations, Langmuir constants and other derived parameters for the adsorption of oleic acid onto MCM-41 (C).

Temperature (°C)	Linear equation	R ²	q _m (mg/g)	K _A (L/mg)
25	y = 0.0037x + 2.0100	0.9972	270.3	1.84 × 10 ⁻³
30	y = 0.0039x + 2.0286	0.9949	256.4	1.92 × 10 ⁻³
40	y = 0.0041x + 1.9384	0.9951	243.9	2.12 × 10 ⁻³
50	y = 0.0062x + 1.6319	0.9940	161.3	3.80 × 10 ⁻³

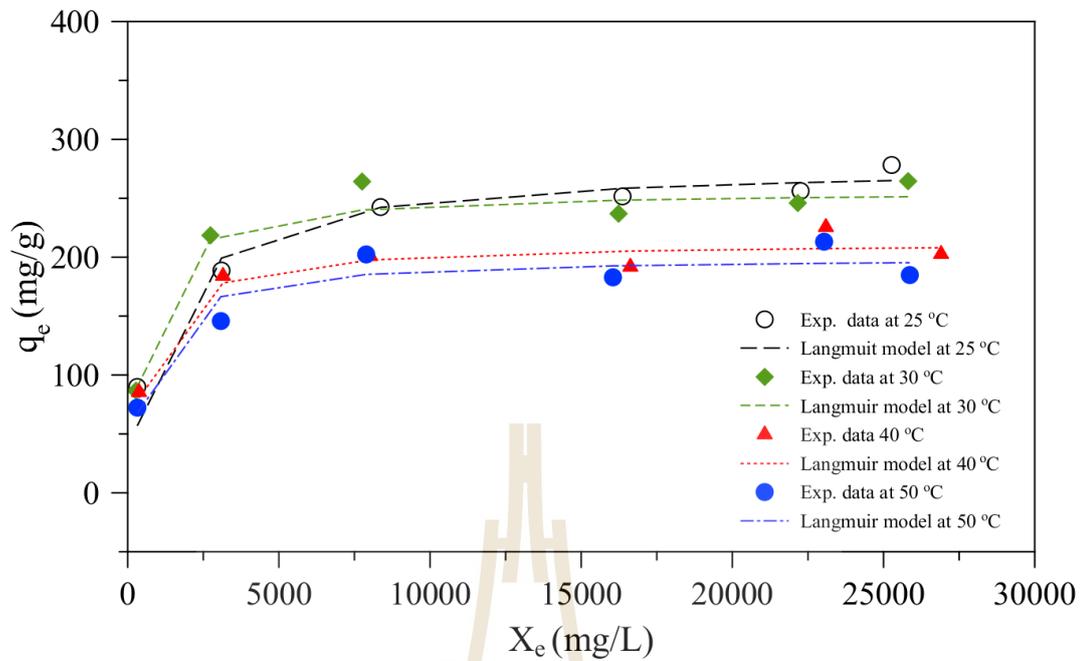

Figure 4.17 Langmuir isotherm models and the experimental data of the adsorption study using MCM-41 (A) at various temperatures.

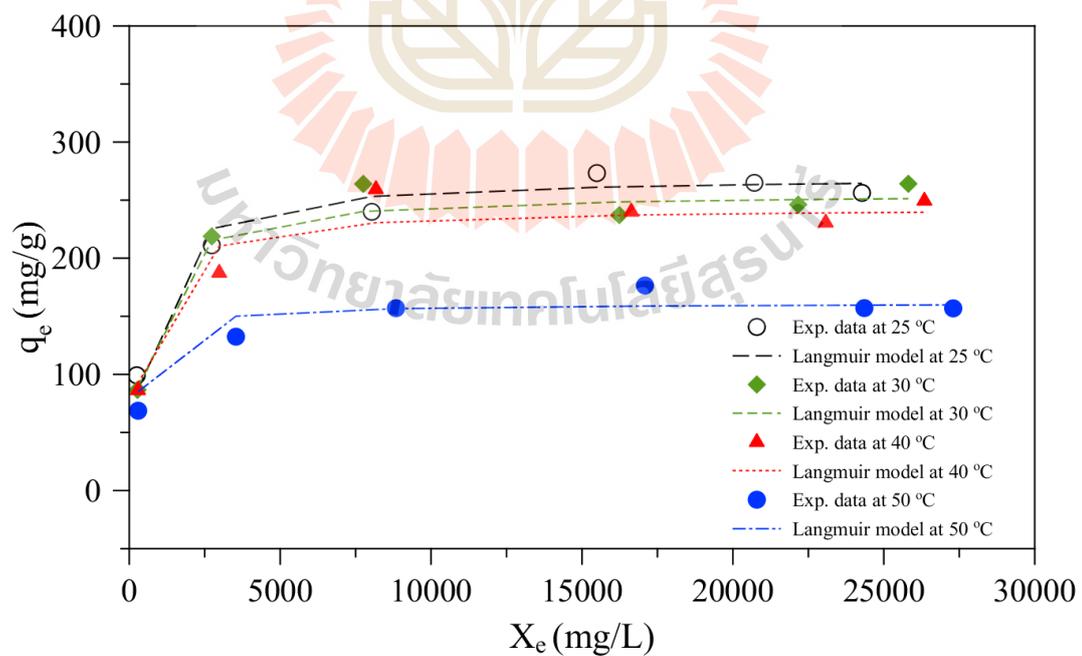

Figure 4.18 Langmuir isotherm models and the experimental data of the adsorption study using MCM-41 (C) at various temperatures.

Other important factor derived from the Langmuir isotherm is the dimensionless constant separation factor, R_L . The value of R_L are summarized in Table 4.8 and 4.9. The value in the range 0-1 indicates that the equilibrium adsorption is favorable at the temperature studied (Adam and Chua, 2004; Dada et al., 2012).

The adsorption data were also correlated to Freundlich isotherm model. The linear form of the Freundlich model for adsorption of oleic acid onto MCM-41 adsorbents can be examined from the plots of $\ln q_e$ versus $\ln X_e$ in the temperature range of 25-50 °C and the results are shown in Table 4.10 and 4.11. The values of R^2 indicate that the adsorption of oleic acid onto the MCM-41 adsorbents does not fit well with the Freundlich isotherm.

Table 4.8 The constant separation factors for the adsorption of oleic acid onto MCM-41 (A) at various initial acid concentrations and temperatures.

Initial concentration (%)	R_L at temperature			
	25 °C	30 °C	40 °C	50 °C

4.5 Thermodynamic parameters

From the adsorption data conducted at different temperatures, enthalpy change (ΔH) and entropy change (ΔS) for the adsorption can be calculated from the slope and intercept of a graph plotting between $\ln K_D$ versus $1/T$ as shown in Figure 4.19 and 4.20. The results are given in Table 4.12. The negative values of ΔH suggest that the adsorption is an exothermic process.

The ΔS is related to variations of the order-disorder in a system. The positive values of ΔS for the adsorption with both adsorbents suggest that the adsorption system was in a higher state of disorder at the equilibrium (Adam and Chua, 2004).

For Gibb free energy change (ΔG) the values were obtained from equation $\Delta G = \Delta H - T\Delta S$ and are shown in Table 4.12. The negative values of ΔG indicate that the adsorption of the acid on both adsorbents is spontaneous (Gupta et al., 2004).

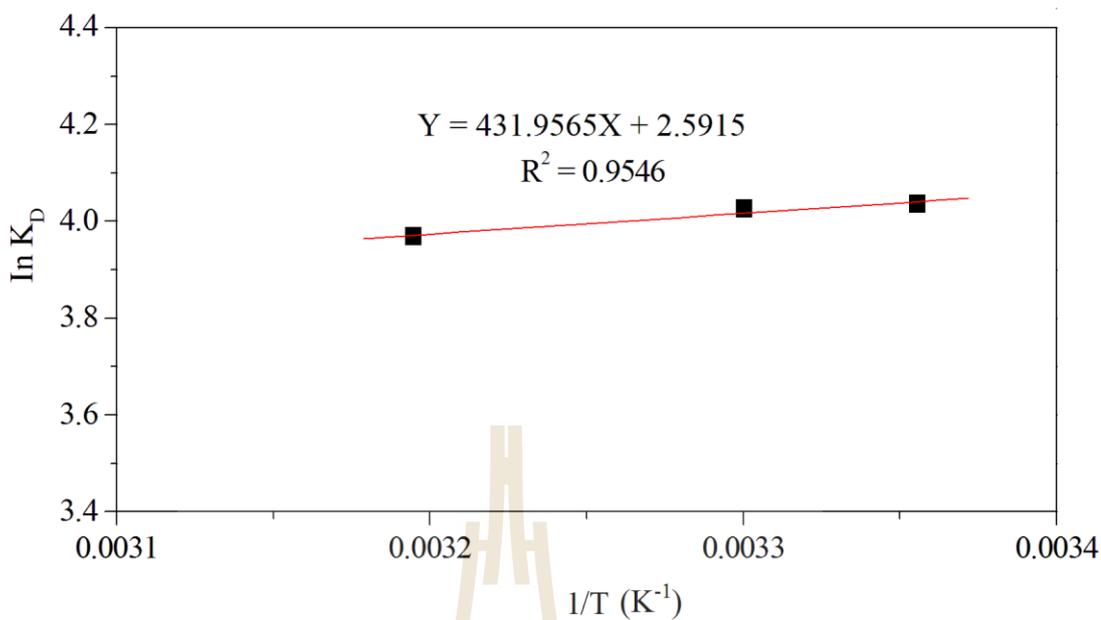

Figure 4.19 The plot of $\ln K_D$ versus $1/T$ for the adsorption of oleic acid with MCM-41 (A). Condition: adsorption time; 60 min, the acid concentration; 118 mg/ 25 mL, the amount of adsorbent; 0.25 g/ 25 mL.

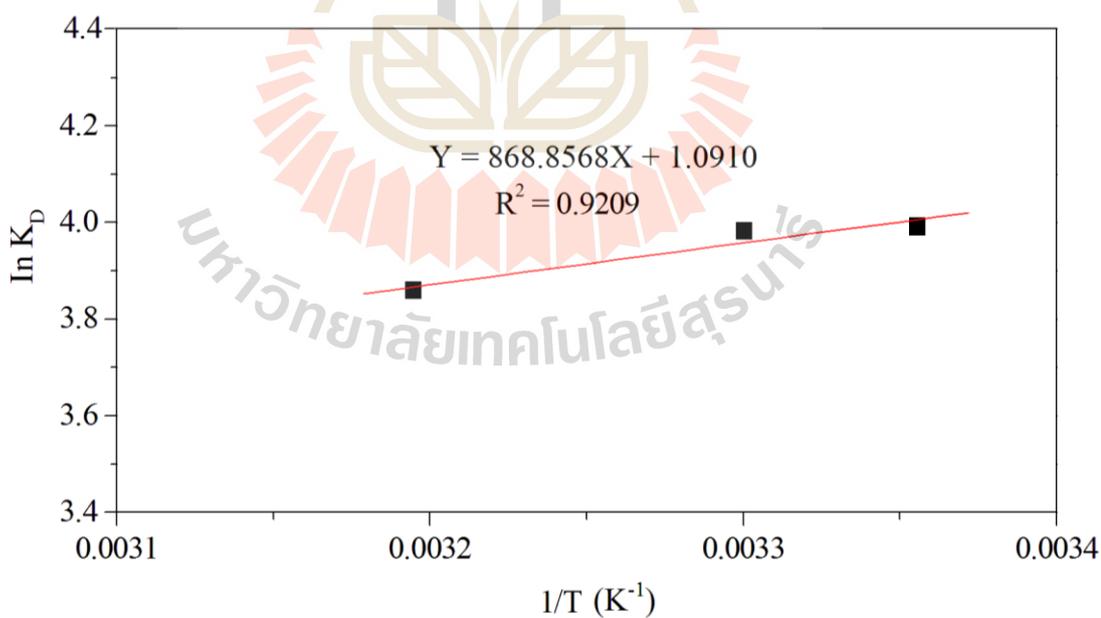

Figure 4.20 The plot of $\ln K_D$ versus $1/T$ for the adsorption of oleic acid with MCM-41 (C). Condition: adsorption time; 60 min, the acid concentration; 118 mg/ 25 mL, the amount of adsorbent; 0.25 g/ 25 mL.

Table 4.12 Thermodynamic parameters for the adsorption of oleic acid onto MCM-41 (A) and MCM-41 (C).

Adsorbent	ΔH (kJ/mol)	ΔS (J/mol)	ΔG (kJ/mol)		
			25 °C	30 °C	40 °C
MCM-41 (A)	-3.59	21.5	-10.01	-10.12	-10.34
MCM-41 (C)	-7.22	9.07	-9.93	-9.97	-10.06

4.6 Adsorption of FFA in soybean oil

Both MCM-41 (A) and MCM-41 (C) were used for the adsorption of 1.0% oleic acid in soybean oil. The mixture of the adsorbent and the acid solution was stirred for 60 min at 25 °C. After that the adsorbent was removed by centrifugation and the amount of the acid in the solution was determined. The results are shown in Table 4.13. The adsorption capacity of MCM-41 (A) was 178.7 mg/g which was lower than that of the adsorption conducted in isoctane, $q_e = 242.5$ mg/g, with the same concentration of oleic acid and adsorption temperature. For MCM-41 (C), the adsorption of the acid was not observed. This could be due to that triacylglycerol could also be adsorbed on the adsorbents via hydrogen bonding of carbonyl group to silanol group (Yates et al., 1997). Because of the bulky structure of the triacylglycerol once adsorbed it could hinder the adsorption of oleic acid on both adsorbents.

Table 4.13 The adsorption capacities of MCM-41 (A) and MCM-41 (C) in soybean oil.

Adsorbent	q_e (mg/g)	% removal
MCM-41 (A)	178.7	16.2
MCM-41 (C)	no adsorption	-

CHAPTER V

CONCLUSION

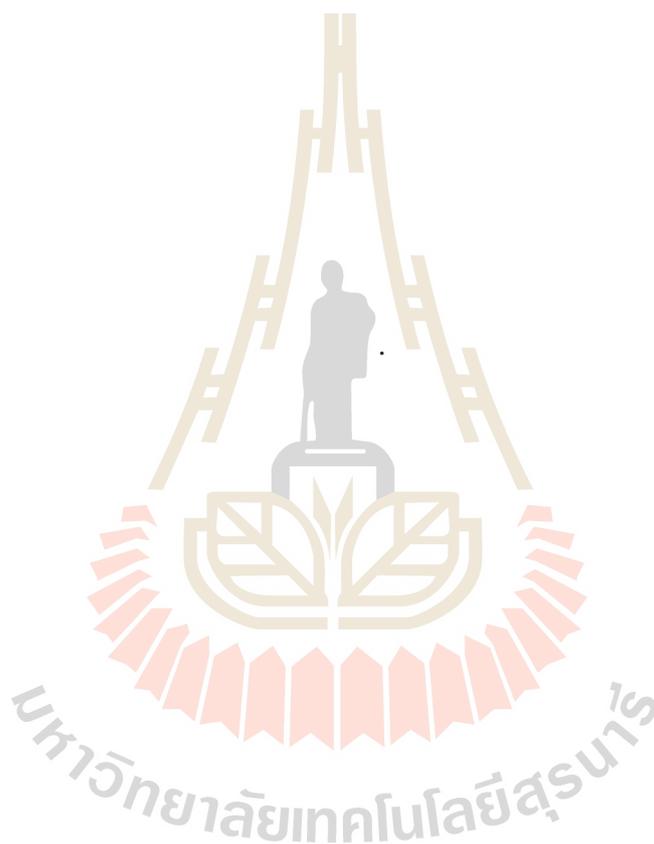

This research focused on the removal of oleic acid in isooctane solutions by adsorption. The adsorbents used in the studies were synthesized from silica extracted from rice husk and they were MOR, MCM-41 (A) and MCM-41 (C). The rice husk silica was also used as the adsorbent.

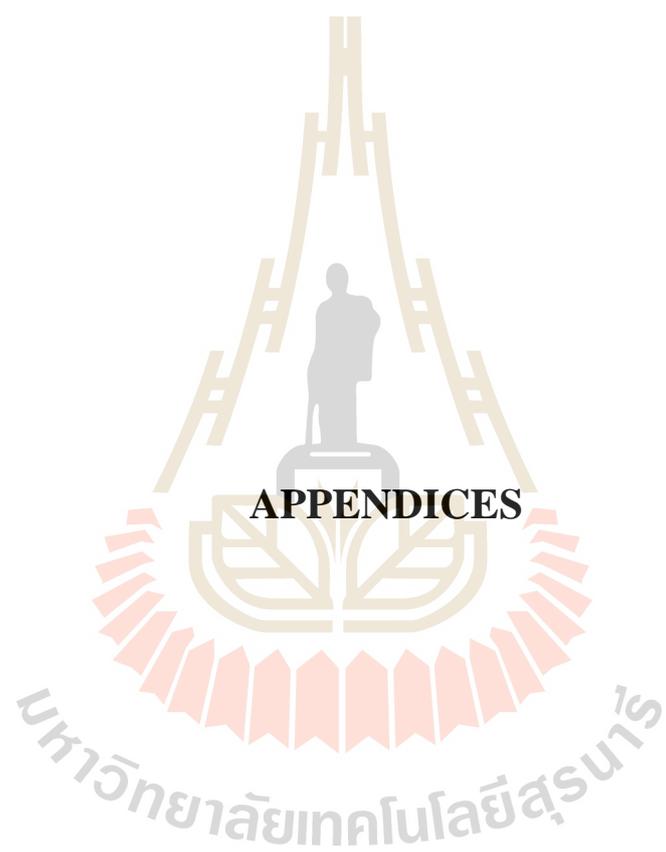

Of all the adsorbents, MCM-41 (A) and MCM-41 (C) were found to be the best adsorbents for oleic acid. The equilibrium adsorption capacity at 25 °C of MCM-41 (A) was 277.8 mg/g and that of MCM-41 (C) was 270.3 mg/g. These were about 4 times higher than those obtained with MOR and silica. Surface area, active sites and appropriate pore size of the adsorbents are the factors that influence for the high adsorption capacity.

The adsorption of oleic acid onto MCM-41 (A) and MCM-41 (C) followed the Langmuir isotherm model. The adsorption processes were spontaneous and exothermic. After the equilibrium adsorption, the systems were in a higher state of randomness.

MCM-41 (A) could be used in the adsorption of oleic acid in soybean oil, although the adsorption capacity was lower due to the adsorption of triacylglycerol onto the adsorbent. To remove a higher amount of the acid from the oil, a larger amount of the adsorbent is recommended.

MCM-41 (A) is a good candidate to be used as the adsorbent for the removal of free fatty acid in the real oil samples, but several issues must be further investigated. The regeneration and reuse of the adsorbent are of interest for economic reasons. The reagent to be used should be investigated. The stability of the surfactant inside the pore of MCM-41 has to be evaluated. Species that might compete for the adsorption must be identified.

CURRICULUM VITAE

Name: Miss Benjaluck Narachai

Date of Birth: September 17th, 1981 in Amnatcharoen, Thailand

E-mail: tawanok@hotmail.com

Telephone: 085-3314497

Education:

2000-2003 B.Sc. (Chemistry), Ubon Ratchathani University

Work experience

June 3, 2004-Mar 11, 2005;

Quality Assurance (Q.A), Community Pharmacy Public Co., Ltd

Mar 16, 2005-Dec 30, 2005;

Research & Development (R&D)

Pan Rajdhevee Group Public Company Limited

Jan 4, 2006-Feb 19, 2009;

Senior Production Engineer, NEC/TOKIN Electronics (Thailand) Co.,

Ltd
