HYBRID PEROVSKITE/X-RAY ABSORPTION SPECTROSCOPY

The emerging of perovskite solar cell has attracted many interests in the synthesis and characterization of hybrid perovskite materials related to methylammonium iodide $\text{CH}_3\text{NH}_3\text{I}$ (MAI) due to various interesting properties. In this work, we found a faster way to synthesis hybrid perovskite MAPbI_3 from MAI precursor is reported. Which can be shortened by a factor of four, from 48 h to 12 h by changing the reduction agent from dimethylformamide (DMF) to acetone. The MAI precursors from acetones were used to synthesis hybrid perovskite MAPbI_3 and $\text{MAPbI}_{(3-x)}\text{Cl}_x$ ($x=0,1,2$) powders by solid state method. Finally, the characterization of MAI, MAPbI_3 and $\text{MAPbI}_{(3-x)}\text{Cl}_x$ powder by X-ray Diffraction (XRD), Infrared Spectroscopy (IR) and X-ray Absorption Spectroscopy (XAS) showed that the characteristic of hybrid perovskite MAPbI_3 and $\text{MAPbI}_{(3-x)}\text{Cl}_x$ powders from acetone and DMF are comparable thus confirm the effectiveness of the new preparation route. From XRD and XAS, we found that Cl cannot substitute for I in X side of perovskite structure (ABX_3) using solid state method.

ACKNOWLEDGEMENTS

There are many people, to whom I would like to express my sincere words of acknowledgments:

I am grateful to my thesis advisor, Assoc. Prof. Dr. Saroj Rujirawat, Prof. Rattikorn Yimnirun and Dr. Usa Sukkha for introducing me to the field of synchrotron x-ray absorption spectroscopy. They supervised this work in all steps, from the very first experiments, new ideas, data processing as well as the final proof reading of the manuscript. Not only their scientific expertise, but also their optimism and trust were a great help and motivation throughout my work.

I am grateful to Dr. Narong Chanlek manager of BL-5.3, SLRI-SUT-nanoTEC and Dr. Pinit Kidkhunthod manager of BL-5.2, SLRI-SUT-nanoTEC at Synchrotron Light Research Institute. I thank them for their great contribution in bringing up new questions and ideas of XPS and XAS technique.

This work has been partially supported by Science Achievement Scholarship of Thailand and the Research Network NANOTECH (RNN) program of the National Nanotechnology Center (NANOTECH), NSTDA, Ministry of Science and Technology, Thailand.

Finally, this thesis is dedicated to my parents and my friends for their love, understanding, and support throughout the progress and for motivating me to complete my study.

Phitsamai Kamonpha

CHAPTER I

INTRODUCTION

1.1 BACKGROUND

Currently, electrical power is increasingly more important for human than ever and it is expected that the future demand for electricity will be increasing more. The trend of world energy consumption by energy source is shown in Figure.1.1. In the past, the most of energy has come from burning fuels such as wood, coal, oil and natural gas, so if we use of these resources for generating electricity, they will cause a greenhouse gas due to the carbon dioxide gas from burned fuel increase and led to global warming. So, renewable energy sources such as biomass, wind, hydropower and led to global warming. So, renewable energy sources such as biomass, wind, and hydropower and solar for generating electricity became attractive because they are environmentally friendly and generated less greenhouse gases. Solar energy is a good choice of renewable energy with plentiful of energy source from the nuclear reaction within the sun. In this work, we focus on material for photovoltaic solar cell for electricity production which is green energy and sustainable. Photovoltaic cells or PV cells are devices for harvesting solar energy and converting it to electricity. The most ordinary material for solar panel production is crystalline silicon which has semiconductor properties. There are four main types of solar panels commercially. available: (1) monocrystalline silicon PV, (2) polycrystalline silicon PV, (3) amorphous silicon PV, (4) hybrid PV (Administration, 2015). Researchers at National Renewable Energy Laboratory (NREL) reported world record one-sun efficiencies of 32.8% for dual-junction GaInP/GaAs

solar cell devices, and the dual-junction device with mechanically stacked silicon solar cells, to achieve a record one-sun efficiency of 35.9% for triple-junction solar cells (figure 1.2).(Essig et al., 2017). Perovskite solar cells became popular recently.

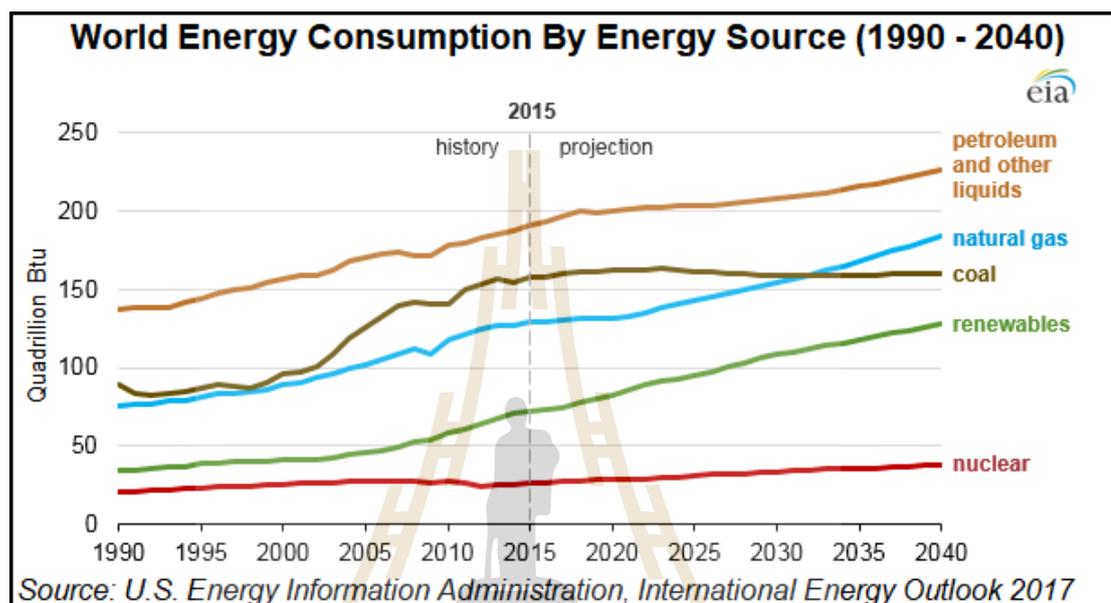

Figure 1.1 World energy consumption by energy source. (Administration, 2015)

Organic-inorganic lead halide perovskites is a photovoltaic material that exhibits high power conversion efficiency (PCE) because of their strong light absorption band across solar spectrum (figure 1.3) and long free carrier diffusion length of few microns. Yanbo Li reported high-efficiency planar $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ (Compared with films derived from mixed $\text{PbI}_2/\text{PbCl}_2$ precursors) perovskite photovoltaics, of 16.8% with highly repeatable (Yu et al., 2014). The performance without any need for a mesoporous or nanocrystalline metal oxide layer (Li et al., 2015). A variety of reports have suggested that Cl enables long photocarrier lifetimes, increases diffusion lengths in halide perovskite materials, and as well as low working temperature. John A. Mc Leon reported that Methyl ammonium lead trihalide ($\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$) perovskite, usually synthesized from two precu-

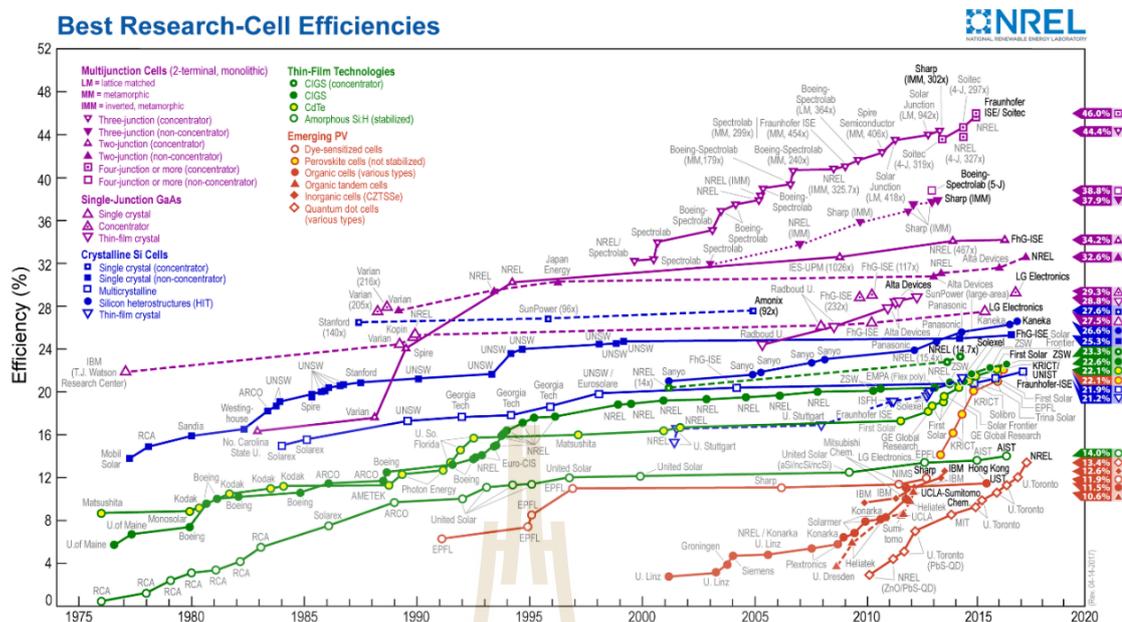

Figure 1.2 Reported timeline of solar cell energy conversion efficiencies (Elseman et al., 2018).

sors, $\text{CH}_3\text{NH}_3\text{I}$ and PbCl_2 at a ratio of 3:1 with slight adjustment of I/Cl ratio in the precursor mixture plays a strong effect on solar cell performance. An in-depth chemical study about the possible impurities formed during $\text{CH}_3\text{NH}_3\text{I}$ preparation was presented and their relevance on solar cell processing is revealed (McLeod et al., 2016). HI was shown to effect iodide coordination. There was a strong correlation between the lead coordination chemistry in precursor solutions and the surface coverage and morphology of the resulting MAPbI_3 film (Sharenko et al., 2017). Impurities can give rise to the better perovskite solar cell devices, compared with impurity-free precursor (Levchuk et al., 2016).

In this work, we will synthesize $\text{CH}_3\text{NH}_3\text{I}$ (MAI) by Sol-gel method using different solvents, to optimize the synthesis time. The synthesis MAI will be characterized to find morphology, functional group, and chemical composition using X-ray Diffraction (XRD), Infrared Spectroscopy (IR) and X-ray absorption spectroscopy (XAS), respectively. Next, the solar cell perovskite materials

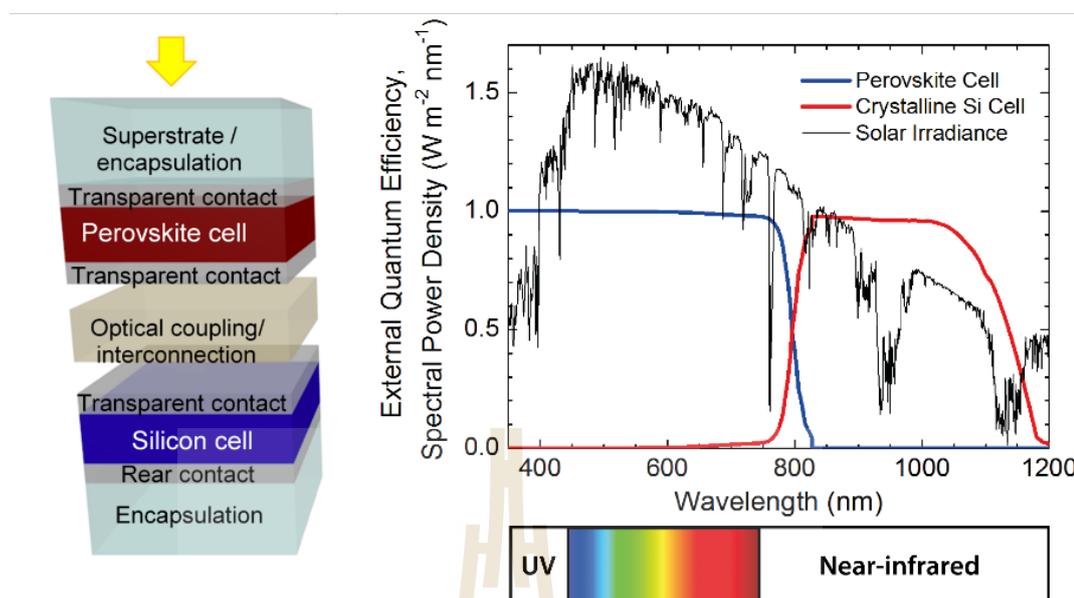

Figure 1.3 Solar radiation spectrum.

$\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ will be synthesized using solid-state method from $\text{CH}_3\text{NH}_3\text{I}$ and PbCl_2 precursors. PbCl_2 precursor will be used to substitute Cl for I in $\text{CH}_3\text{NH}_3\text{PbI}_3$ to improve thermal stability and devices lifetime. After synthesis $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ will be analyzed to find the structure, size, and morphology by x-ray diffraction (XRD) and Scanning electron microscope (SEM). The chemical composition, local structure and electronic structure will be studied by Energy-dispersive X-ray spectroscopy (EDX), Infrared spectroscopy (IR), X-ray absorption spectroscopy (XAS) and X-ray photoelectron spectroscopy (XPS).

1.2 REVIEW OF LITERATURES

1.2.1 Structure of perovskite

Perovskite is named of Russian mineralogist Count Lev Alekseevich perovski (1792-1858) and discovered by Gustav Rose in 19th century in Ural Mountains of Russia. The name of perovskite refers to all material with the same crystal

structure as calcium titanium oxide or calcium titanate (CaTiO_3). The general chemical formula of perovskite is ABX_3 . In this formula 'A' and 'B' are to cation of different sizes (A cation are larger than the B cation.), and 'X' is an anion that bonds to 'A' and 'B' cation. The 'A' cation is an alkaline earth or rare earth element as Cesium, Calcium and Natrium (In type of hybrid perovskite or organic-inorganic perovskites, A is methylammonium (MA) or Formamidine (FA), The 'B' cation could be a 3d,4d or 5d transition metal as Ti ,Pb, Sn and Fe. And X anion is halogen group e.g. O, Cl, Br and I.

The crystallography of perovskite can be represented in multiple ways. The simplest way to think about a cubic structure and 'A' cations are positioned in corner, 'B' cations at the body center and 'X' anions at face center of the perovskite cube structure. The second way a large atomic or 'A' cations (positively charged) in the center of a cube. The corners of the cube are occupied by 'B' cation (also positively charged cations) and the faces of the cube are occupied by a smaller atom X with negative charge (anion). Crystal of perovskite could be black, brown, gray and orange to yellow color. These crystals appear as cubes, but they are actually pseudo cubic.

1.2.2 Organo-Metal halide perovskites

We focus on a hybrid perovskite based on organic-inorganic trihalide perovskites. From the figure 1.6 organic-inorganic trihalide perovskites is one of kind perovskite in halide group. They have chemical formula ABX_3 , where A is an organic group the methylammonium (CH_3NH_3) (MA) or formamidine [$\text{HC}(\text{NH}_2)_2$] (FA) cation, B is commonly lead (Pb) and X is a halide (Cl, Br, or I). methylammonium lead halide (MAPbX_3 , where MA is methylammonium CH_3NH_3 and X is a halogen) perovskites have good absorber for visible light because they are very

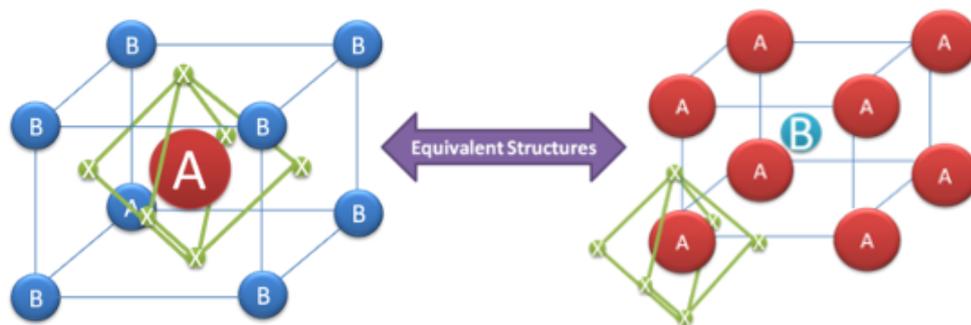

Figure 1.4 A generic perovskite crystal structure of the form ABX_3 . Note that the two structures are equivalent – the left-hand structure is drawn so that atom B is at the $\langle 0,0,0 \rangle$ position while the right-hand structure is drawn so that atom (or molecule) A is at the $\langle 0,0,0 \rangle$ position. Also note that the lines are a guide to represent crystal orientation rather than bonding patterns.

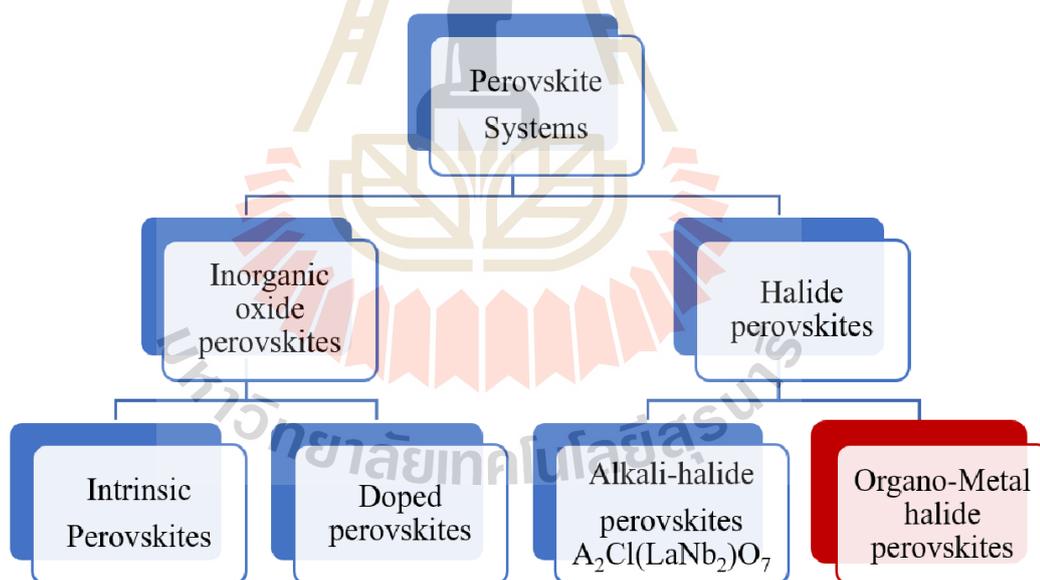

Figure 1.5 Classification of perovskite system.

well of managing chemical compositions, ambipolar charge transport, and very long electron-hole diffusion lengths so they are very good of optical properties.

M. A. Green et al, present about organometallic halide perovskites is a kind of

perovskite structural crystalline materials are consisting of organic methylamine and inorganic lead halide, it's rapidly become promising semiconductors for solar cell applications and can increase the power conversion efficiencies from less than 4% in 2009 to over 20% now for methylammonium lead iodide ($\text{CH}_3\text{NH}_3\text{PbI}_3$) (Green et al., 2015). Owing to $\text{CH}_3\text{NH}_3\text{PbI}_3$ have a band gap of 1.55-1.60 eV. In addition, perovskite materials can have applied to light absorbers in thin or thick mesoscopic metal oxides and planar heterojunction solar devices.

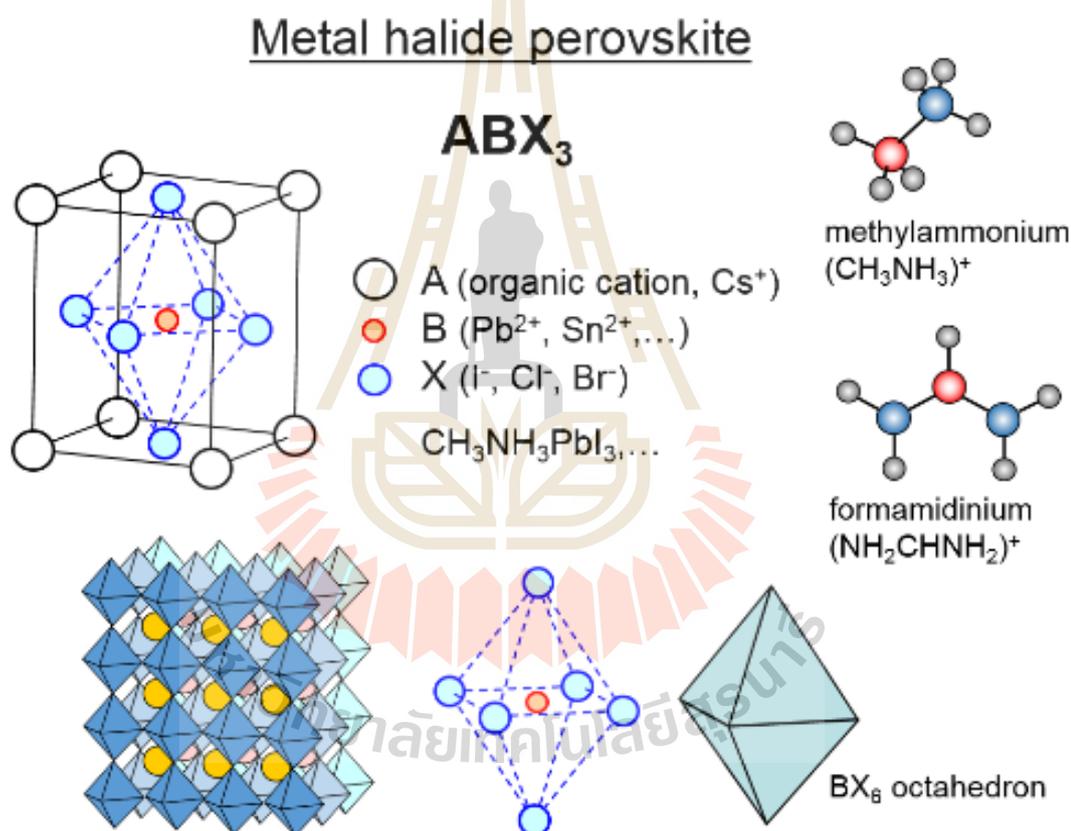

Figure 1.6 A generic Organo Metal halide perovskite crystal structure.

From ABX_3 in figure 1.6 we will be varying the X site, one group has found that using small chloride ions rather than large iodides improves stability. Jarvis M. Frost represent about compared electrostatic lattice energy and site Madelung potentials for a range of ABX_3 perovskite structures (Cubic lattice, $a = 6.00 \text{ \AA}$)

assuming the formal oxidation state of each species. They found group VII anions are the electrostatic stabilization and the lattice energy increases as the charge imbalance between A and B sites is removed more than VI anions due to the group VII or halide are weak bonding, less-confining, potential, lower ionization potentials (work functions), when they compared with metal oxides. And for X they use halide group for balance cation, as demonstrated in the series of hybrid structures with lower dimensionality in the inorganic networks. For layered structures, the crystal properties become highly anisotropic (Frost et al., 2014). Yanbo Li reported about a new method for achieving high efficiency planar $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ perovskite photovoltaics by annealing and exposure to $\text{CH}_3\text{NH}_3\text{I}$ vapor at low pressure for comparison with films derived from mixed $\text{PbI}_2/\text{PbCl}_2$ precursors.

Table 1.1 Device performance of perovskite solar cells. (^a standard derivation calculated on 8 devices. ^b standard derivation calculated on 32 devices.)

Formula	$J_{SC}(\text{mA}/\text{cm}^2)$	$V_{OC}(\text{V})$	FF	PCE(%)
$\text{MAPbI}_3(\text{average})^a$	20.9 ± 0.4	1.00 ± 0.01	0.68 ± 0.01	14.2 ± 0.3
$\text{MAPbI}_{(3-x)}\text{Cl}_x(\text{best})$	21.7	1.04	0.75	16.8
$\text{MAPbI}_{(3-x)}\text{Cl}_x(\text{average})^b$	21.3 ± 0.6	1.00 ± 0.02	0.73 ± 0.02	15.7 ± 0.07

Therefore chloride (Cl) enables long photocarrier lifetimes and increased diffusion lengths in halide perovskite materials, it's summarized in table 1.1 And the heterojunction devices based on this hybrid halide perovskite exhibit a top PCE of 16.8%. And found chloride can be a success photoluminescence lifetime which was enhanced by nearly an order of magnitude and an improved power conversion efficiency from 13% to 15.3% and 16.5% after treated solar cells by thiophene and pyridine, respectively (Noel et al., 2014). From the table 1.1 they mixed halide perovskite phase crystalline $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ gives the best device performance.

It can alter the band gap, giving both electron and hole diffusion lengths more than $1\ \mu\text{m}$, compared with the effective diffusion length of $\text{CH}_3\text{NH}_3\text{PbI}_3$ for holes but a shorter one for electrons (Stranks et al., 2013). The extra-long carrier diffusion length is contributed to the better efficiency of the solar cell, so we can have improved device performance by doped chloride in a crystal structure, and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ is found to possess an almost identical crystal structure and electronic structure as $\text{CH}_3\text{NH}_3\text{PbI}_3$ as characterized by X-ray diffraction (XRD) and X-ray photoelectron spectroscopy (XPS) (McLeod et al., 2016).

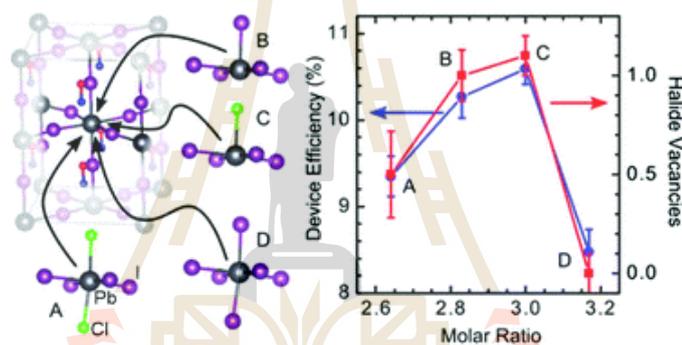

Figure 1.7 Structures of Pb coordinated by I, Cl, nearby CH_3NH_3 and The PCEs of the devices (blue), the number of halide vacancies from EXAFS fitting (red).

The Cl replaced on I in crystal structure of perovskite not clear that what reason bring about increasing of PCE, but it can be used to explain why $\text{CH}_3\text{NH}_3\text{PbI}_3$, if used as an absorber in a flat design (i.e., without mesoporous scaffold), has efficiencies of 2–3%, while with $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ nearly 16% can be reached. Furthermore, structure of perovskite about Cl substitute I in perovskite that was reported by J. A. McLeod. about the influence of I/Cl ratio on the performance of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ based solar cells and found the crystal structure of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ formed from $\text{CH}_3\text{NH}_3\text{I}$ and PbCl_2 precursors with molar ratios of 2.64:1, 2.83:1, 3.0: and 3.17:1. They found Structures of Pb

coordinated by I, Cl, nearby CH_3NH_3 and after change ratio of $\text{CH}_3\text{NH}_3\text{I}$ and PbCl_2 , the films with lower ratios have lower PCEs, they still exhibit many of the same structural and electronic properties as the ideal 3:1 perovskites and at the ratio 3:1 are the highest PCE (shown in figure 1.6 and table 1.2). In this work, we choose to study $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ in the molar ratio of 3:1.

Table 1.2 Electrical output characteristics of the devices with perovskite films with different $\text{CH}_3\text{NH}_3\text{I}/\text{PbCl}_2$ ratios under light at stimulated AM 1.5 solar illumination at 100 mW cm^{-2} . V_{OC} : open circuit voltage, J_{SC} : short circuit current density, FF: fill factor.

$\text{CH}_3\text{NH}_3\text{I}/\text{PbCl}_2$	$V_{OC}(\text{V})$	$J_{SC}(\text{mA}/\text{cm}^2)$	FF	PCE(%)
2.64:1	0.96 ± 0.01	15.35 ± 0.23	0.64 ± 0.03	9.35 ± 0.23
2.83:1	0.90 ± 0.01	16.60 ± 0.18	0.69 ± 0.02	10.27 ± 0.25
3.00:1	0.94 ± 0.01	17.07 ± 0.26	0.69 ± 0.02	10.59 ± 0.18
3.17:1	0.96 ± 0.01	13.96 ± 0.64	0.61 ± 0.03	8.47 ± 0.27

After study literature about perovskite, such as effect from the compound is consist in the crystal structure, temperature and time to annealing, the process to synthesize and fabricated device. We interested to study properties of perovskite structure from different temperature and times for annealing. Then in this work we will prepare material by the sol-gel and solid-state method due to Sol-gel method is a method for producing solid materials from small molecules. The method is used for the fabrication of metal oxides, the process involves conversion of monomers into a colloidal solution (sol) that acts as the precursor for an integrated network (or gel) of either discrete particles or network polymers and solid-state reaction is a chemically react without the presence of any solvent at high temperatures yielding a product which a stable, both method is easy to synthesize and appropriate for

produce powder of perovskite. In sol-gel method, we will vary the solution for reduced iodide (I_2) from CH_3NH_3I salt by different type because we want a powder product for following next step.

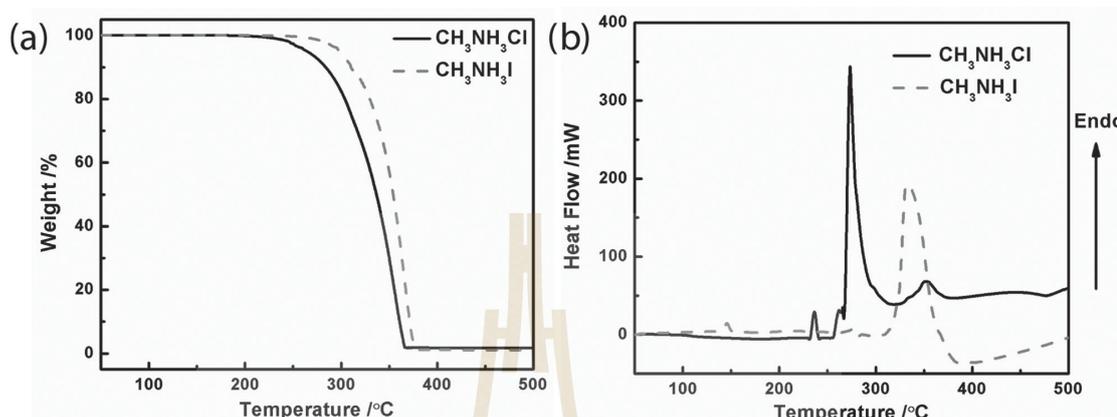

Figure 1.8 a) TGA and b) DSC curves for CH_3NH_3I and CH_3NH_3Cl powders (Zhang et al., 2014).

Table 1.3 Temperature for annealing and PCE of materials (Liu et al., 2015), (Noel et al., 2014), (Jeon et al., 2014), (Shao et al., 2014), (Yu et al., 2014), (Zhang et al., 2014), (Li et al., 2015).

Formula	Temperature(°C) for annealing	Times (minutes)	PCE(%)	Methods
$MAPbI_{(3-x)}Cl_x$	140	20	10.5	Sol-gel& spin costing
$MAPbI_{(3-x)}Cl_x$	90	180	13 → 15	Sol-gel& spin costing
$MAPbI_{(1-x)Br_x}I_3$	100	10	16.2	Sol-gel& spin costing
$MAPbI_3$	110	20	15.6	Sol-gel& spin costing
$MAPbI_{(3-x)}Cl_x$	100,130,150*	50,20,20 *	12*	Sol-gel& spin costing
$MAPb(I,Br,Cl)_3$	100	30	16	Sol-gel& Solid State
$MAPbI_{(3-x)}Cl_x$	120	120	15.7	Sol-gel& spin costing

We unnecessary to dissolve salt of $\text{CH}_3\text{NH}_3\text{I}$. After finished in the sol-gel method we prepared the compound of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ by the solid-state method and followed by annealing at a different temperature. The temperature for annealing we reference by TGA and DSC (figure 1.8) and summarized from literature review about synthesis perovskite on table 1.3 Then, from data in table 1.3 and figure 1.8, we will should temperature to annealing in range of 100 - 250 °C at 30-120 minutes for synthesis crystal structure.

1.2.3 Phases and optical of hybrid perovskite

In general features of hybrid perovskite, they have a different phase in differences temperature with the cubic phase at a high temperature and the Tetragonal phase being the stable phase at room temperature and the Orthorhombic phase at a low temperature. The crystal structure of of organic- halide perovskite shows in table 1.4. And in Figure 1.9 shows the three initial simple cubic structures and phase transition of MAPbI_3 perovskite. The transition from cubic to tetragonal happened at very low temperature around 330 Kelvin degrees. which is a temperature reached during the salvation process.

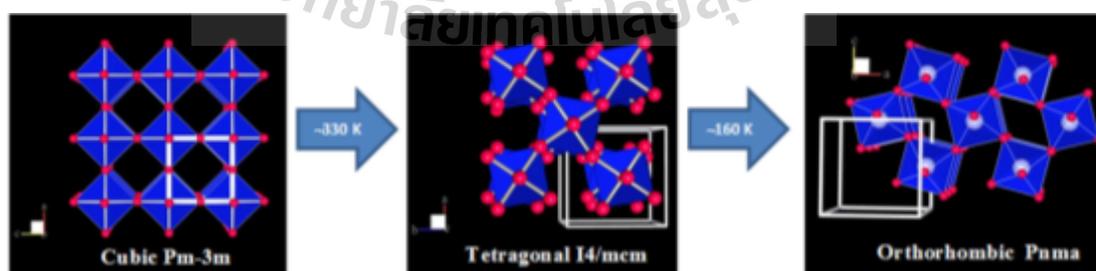

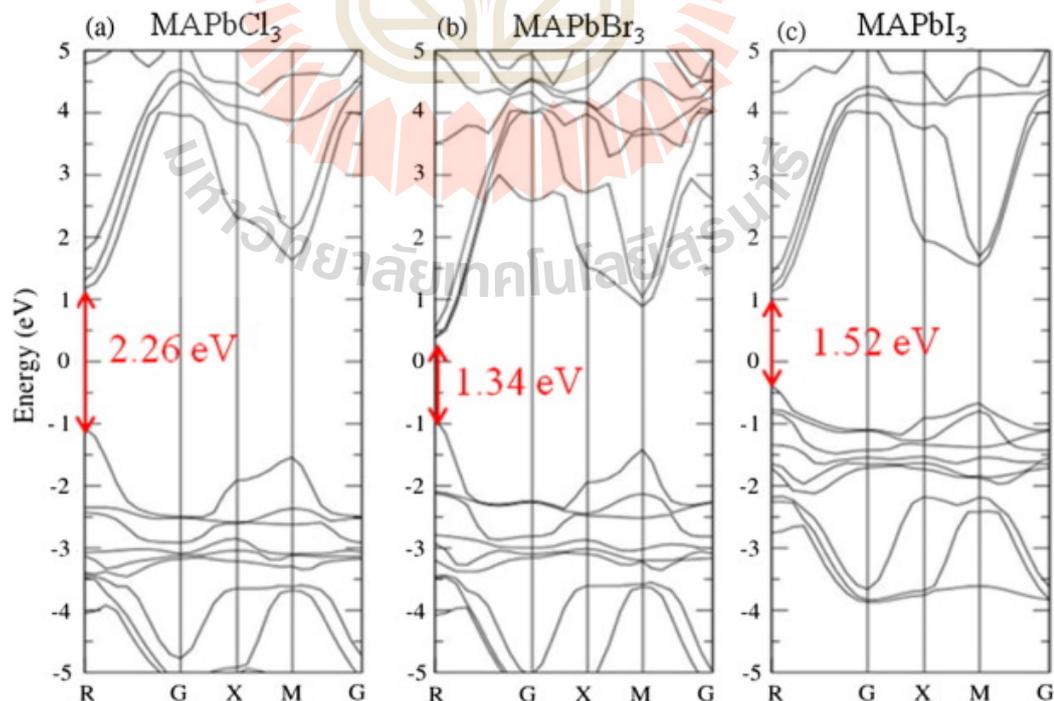

Figure 1.9 Phase transition of MAPbI_3 perovskite.

The brillouin zone of simple cubic structure is shown in Figure 1.10 To draw all the K point for simple cubic structure, it must draw from C point

Table 1.4 Crystal structures of $\text{CH}_3\text{NH}_3\text{PbX}_3$ (X=Cl, Br, I) (Oku, 2015).

Material	$\text{CH}_3\text{NH}_3\text{PbCl}_3$	$\text{CH}_3\text{NH}_3\text{PbBr}_3$	$\text{CH}_3\text{NH}_3\text{PbI}_3$
Crystal system	Cubic	Cubic	Cubic
Transition temperature(K)	177	236	330

(Gamma, this calculation abbreviated to G), to M, R, G, X, M, G, R, X points. The energies of MAPbBr_3 , MAPbI_3 and MAPbCl_3 increase 1.34, 1.52 and 2.26 eV, respectively. large bandgap is used for short wavelength (blue/violet) , and small bandgap for long wavelength.

**Figure 1.10** E-k diagram of MAPbX_3 (Pan et al., 2016).

1.3 RESEARCH OBJECTIVES

The objectives of this research are as follows:

1.3.1 To examine the possibility of synthesizing $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound.

1.3.2 To characterize the synthesized $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound using advanced characterization tools.

1.3.3 To study the optical properties of the $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound by light absorber technique.

1.3.4 To investigate other properties of the synthesized $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound in relation to its application in solar cells.

1.4 SCOPE AND LIMITATIONS

1.4.1 This study focuses on the synthesis of $\text{CH}_3\text{NH}_3\text{I}$ compound by sol-gel method and preparation of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound by solid-state reaction method.

1.4.2 The phase identification, structure characterization and the effect of temperature on the synthesized compound will be investigated using XRD to look at the structure of the compound and, IR Spectroscopy, TG-DTA techniques.

1.4.3 The chemical state and electronic state of the synthesized $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ compound will be investigated using the XPS and XAS technique.

CHAPTER II

RESEARCH METHODOLOGY

2.1 SYNTHESIS

2.1.1 Precursor preparation and $\text{CH}_3\text{NH}_3\text{I}$ analysis

$\text{CH}_3\text{NH}_3\text{I}$ was synthesized in an ice-water bath condition (0°C) for 2 hrs. by reacting methylamine (CH_3NH_2 , 40 wt.% aqueous solution) with hydroiodic acid (HI, 57 wt.% aqueous solution), slowly add hydroiodic acid to methylamine. After we mixed HI and methylamine in ice bath, we heat the mixture to 50°C . And got sero-gel after heating at 50°C around 8 hrs. We washed a sero-gel for several times with Acetone after that we separate them into 2 parts. For drying in air at room temperature and for drying at 60°C in Ar. And in this process, we found $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar have a stability than $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Air.

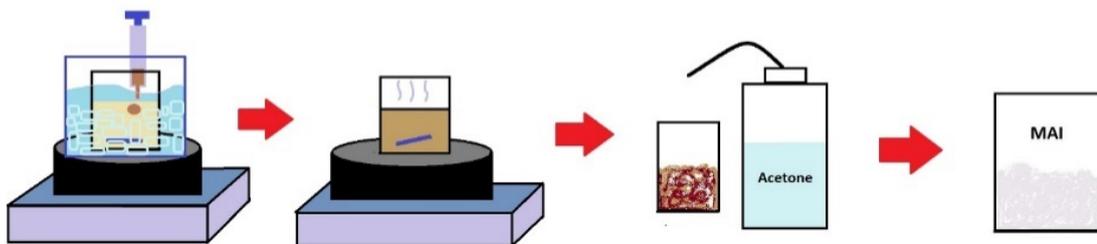

Figure 2.1 Schematic of sol-gel method.

The stability of $\text{CH}_3\text{NH}_3\text{I}$ depend on moisture, oxygen, and UV radiation. Interaction in the decomposed process shows in the equilibrium of reaction (1)-(3) leads to the co-existence of $\text{CH}_3\text{NH}_3\text{I}$, CH_3NH_2 , and HI in the powder.

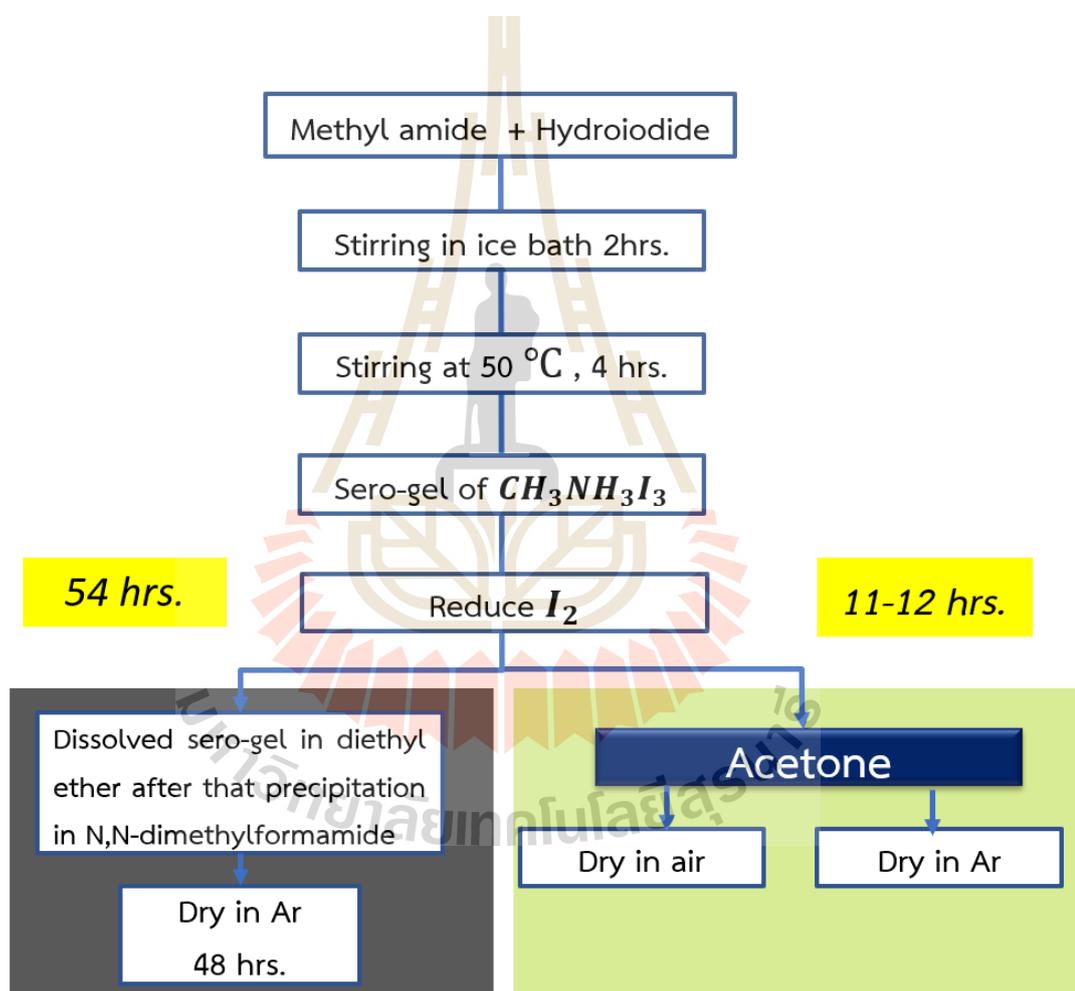

Figure 2.2 Schematic diagrams for $\text{CH}_3\text{NH}_3\text{I}$ preparation.

The color change of $\text{CH}_3\text{NH}_3\text{I}$ under different conditions process demonstrated that only air and UV radiation could lead to the brown color, which is due to the existence of I_2 (Niu et al., 2015).

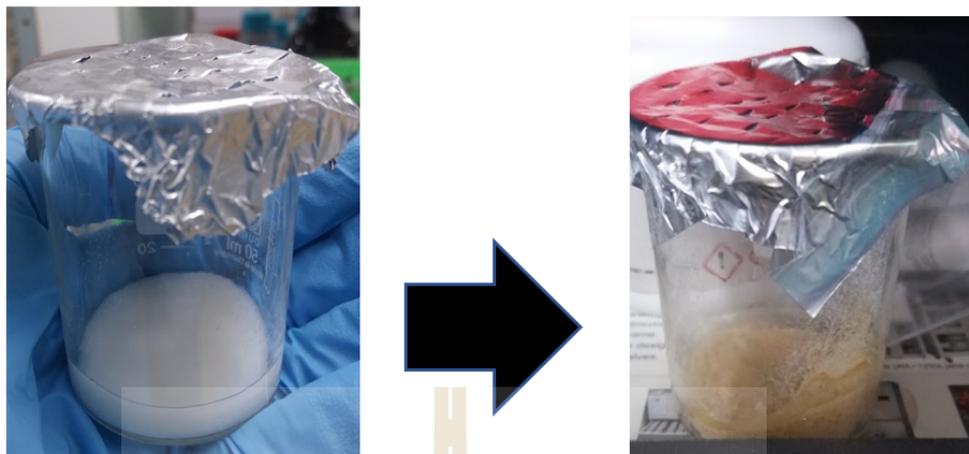

Figure 2.3 The redox reaction of $\text{CH}_3\text{NH}_3\text{I}$.

2.1.2 Preparation $\text{CH}_3\text{NH}_3\text{PbI}_3$ and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ analysis

The mixed halide perovskite ($\text{CH}_3\text{NH}_3\text{PbI}_3$) were prepared in nitrogen-filled glovebox by solid state method a precursor solution of $\text{CH}_3\text{NH}_3\text{I}$ and PbI_2 at a 1:1 molar ratio, followed by thermal annealing at different temperatures and times. And $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder were prepared in nitrogen-filled glovebox by solid state method a precursor solution of $\text{CH}_3\text{NH}_3\text{I}$ and PbCl_2 at a 3:1, 2:1, 1:1 molar ratio, followed by thermal annealing at different temperatures and times.

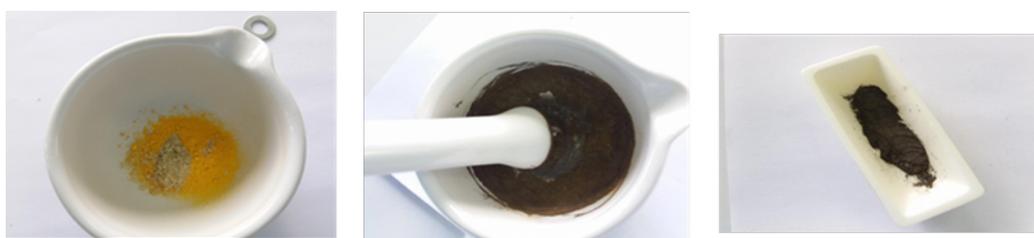

Figure 2.4 Solid state method.

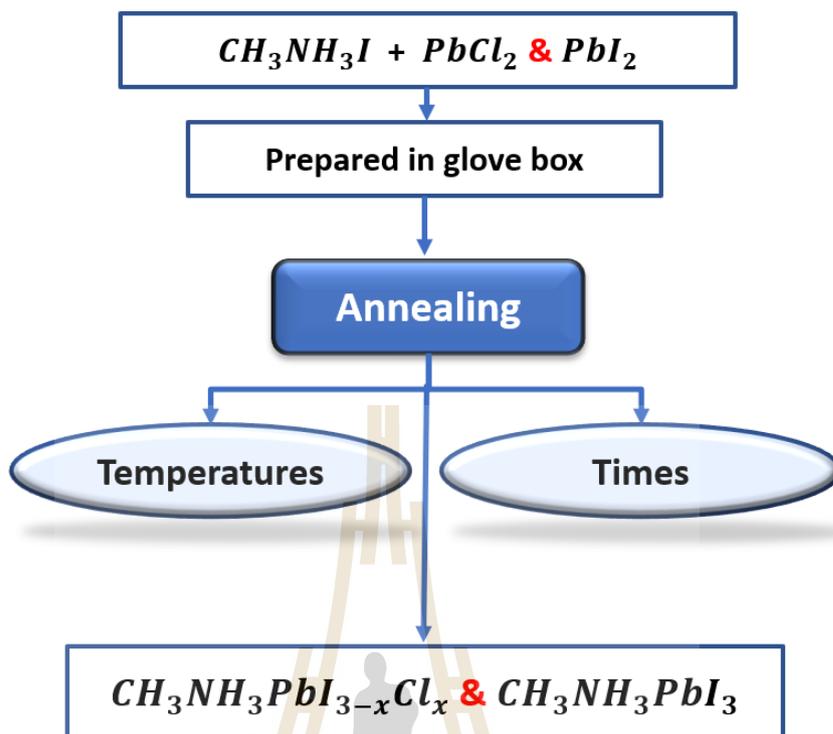

Figure 2.5 Schematic diagrams for $(\text{CH}_3\text{NH}_3\text{PbI}_3$ and $(\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x)$ preparation.

2.1.3 Devices

We prepared perovskite devices by spin-coating process and preparation substrate follow schematic in figure 2.6. After we prepared substrates. We are creating perovskite film as follow. First, a mixture of $\text{CH}_3\text{NH}_3\text{PbI}_3$, GBL and DMSO in the appropriate ratio is spread over the entire surface of the substrate. Second, the spin-coater is accelerated to the desired rotational speed and maintained there for several tens of seconds to evaporate the solvent. Third, a solvent that does not dissolve the perovskite materials and is miscible with DMSO and GBL (for example, toluene or chloroform) dripped on the substrate during spinning. Fourth, all constituents are frozen into a uniform layer on the removal of the residual DMSO and then a new complex as an intermediate phase is formed (see in figure 2.7).

Finally, the complex is converted into highly uniform and crystalline perovskite on annealing at 100°C for 10 minutes.

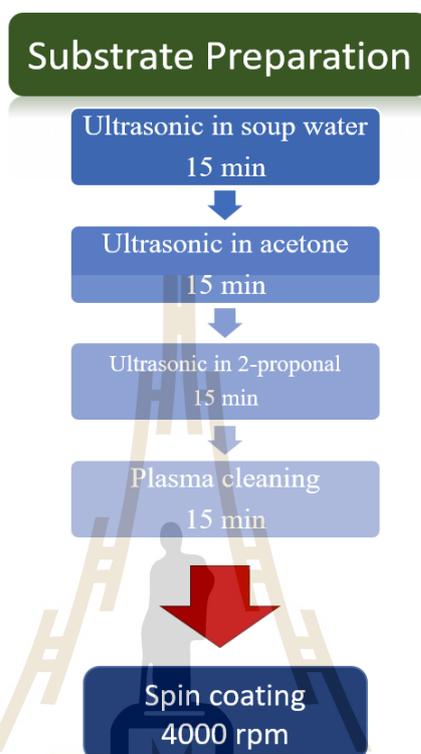

Figure 2.6 Schematic of prepared film method.

Figure 2.7 The precursor for prepared $\text{CH}_3\text{NH}_3\text{PbI}_3$, $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$. And film after annealing.

2.2 CHARACTERIZATION

2.2.1 X-Ray Diffractometer (XRD)

X-ray diffraction analysis (XRD) is a common analytical technique for study phase identification of crystalline materials from breakage faces of samples and can provide information on unit cell dimensions.

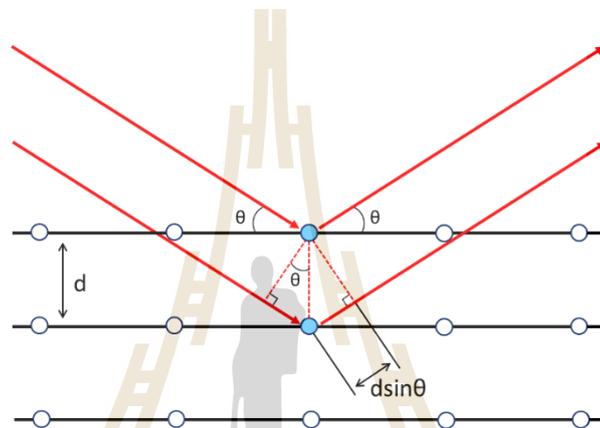

Figure 2.8 Bragg diffraction. Two beams with identical wavelength and phase approach a crystalline solid and are scattered off two different atoms within it. The lower beam traverses an extra length of $2d\sin\theta$. Constructive interference occurs when this length is equal to an integer multiple of the wavelength of the radiation.

The X-ray diffraction methods was start from generate X-ray by a cathode ray tube, filtered to produce monochromatic radiation, collimated to concentrate, and directed toward the sample. When the detector moves in a circle around the sample, X-ray waves incident on an atom of sample, the X-ray waves are scattered from lattice planes and produces constructive interference from a separated of waves in the interplanar distance d . The detector will be recording the number of X-ray by observed at each angle 2θ .

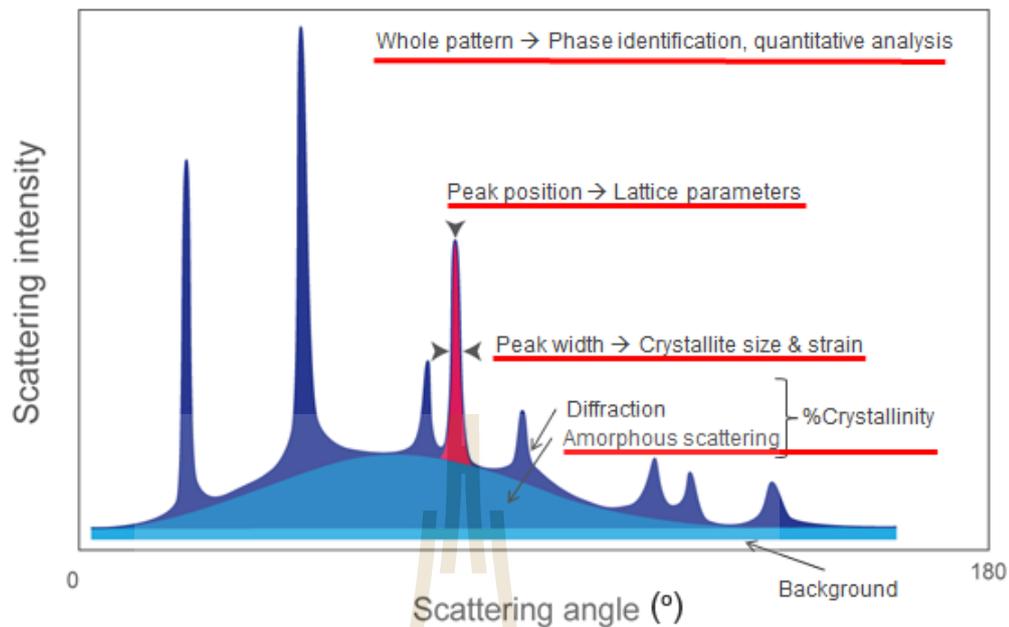

Figure 2.9 The schematic of XRD pattern and information obtainable. (<https://nptel.ac.in/courses/115103030/3>).

The relation of wavelength of electromagnetic radiation to the diffraction angle and the lattice spacing in a crystalline sample is Bragg's Law. when conditions satisfy Bragg's Law equation is

$$n = 2d \sin \theta \quad (2.1)$$

Where θ is the scattering angle, n is a positive integer and λ is the wavelength of the incident wave.

When X-ray from source reflects on any lattice in crystal, The incident light from lattice in crystal bring about many diffraction patterns and the patterns reflect show the characterization of the structure. And the characteristic x-ray diffraction pattern lead to a typical XRD analysis. Then the X-ray diffraction patterns are the fingerprint of all crystal. And can identify the pattern of crystalline by compared with standard reference patterns.

We can calculate d -spacing and lattice parameters for the cubic from the relation between the lattice constant and d_{hkl} by using equation 2.2 and cubic system as shown in figure 2.10.

$$d_{hkl} = \frac{a}{\sqrt{h^2 + k^2 + l^2}} \quad (2.2)$$

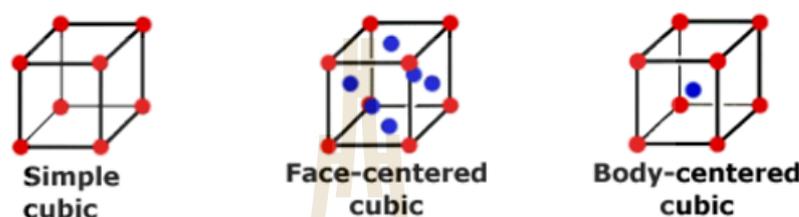

Figure 2.10 Schematic of different cubic systems.

2.2.2 Infrared Spectroscopy (IR)

We used infrared spectroscopy (IR) to determine a functional group of organic compounds. The molecules of compound absorb have a specific frequency of light in range of IR (see in figure 2.11). The infrared region covers a spectrum wavelength range from 0.78 mm to 1000 mm. In the context of infrared spectroscopy, wavelength is measured in “wavenumbers”, which have the units cm^{-1} and the most useful for analysis region lies from 4000 to 670 cm^{-1} .

When applied infrared radiation energies equal to the natural frequency of vibration of compound (different types of bonds absorb at different energies). The covalent bonds in molecules absorb this energy and excited to the higher energy state (from ground state). The result from the excitation takes a peak is observed. Then the infrared radiation energies from peak can indicate to the energy of functional group and the bond stretching or bending in most molecules. A sample of typical infrared absorption frequencies shown in figure 2.12.

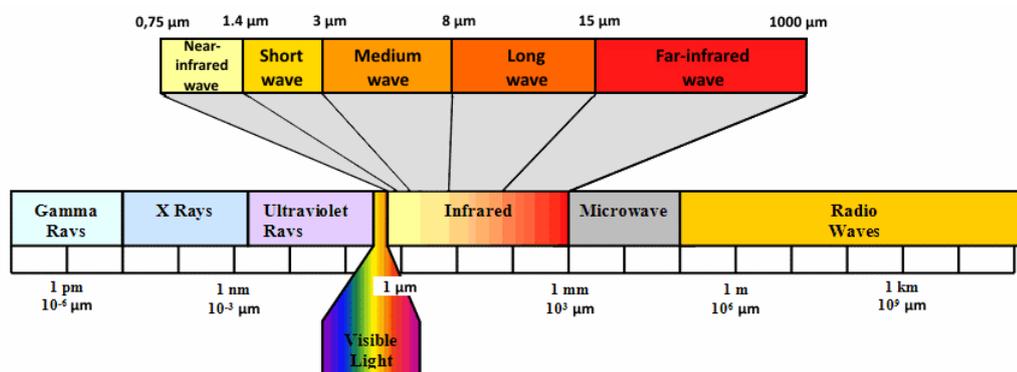

Figure 2.11 Range of infrareds.(www.pro-therm.com/images/infrared_basics)

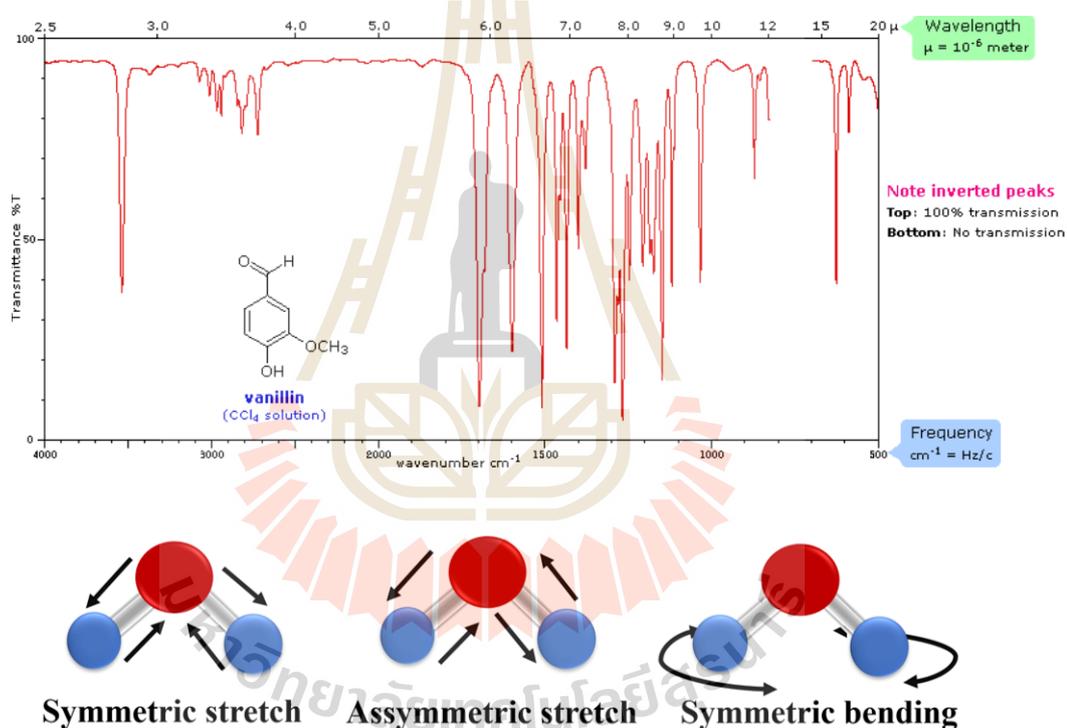

Figure 2.12 Graph of the IR spectrum and molecular vibrations.

The principle of IR instrument show in figure 2.13. The IR light from the source separate into two and passed through the reference and the sample. After light passed sample and reference and then through a detector. Finally, the light is converted into signals and displayed on the screen.

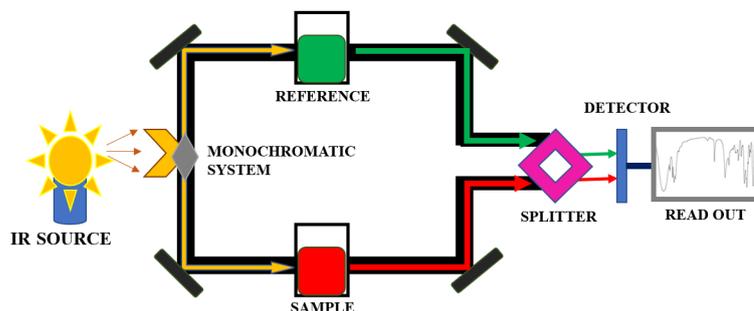

Figure 2.13 Graph of the IR spectrum and molecular vibrations.

2.2.3 Scanning electron microscopy (SEM) and energy-dispersive X-ray (EDX)

Scanning electron microscopy (SEM) is a technique for obtain high resolution images of sample by scanning over the surfaces. The high resolution image generated from black scattering of high-energy electrons emitted. Areas range of emitted approximately 1 cm to 5 microns in width. For modern SEMs can emitted in order of 2 nm. (magnification ranging from 20X to approximately 30,000X, spatial resolution of 50 to 100 nm). Scanning Electron Microscopy (SEM) have significant components of all SEMs include, electron source ("Gun"), electron lenses, sample stage, detectors for all signals of interest, display / data output devices and infrastructure requirements have power supply, vacuum system cooling system, vibration-free floor and room free of ambient magnetic and electric fields followed in figure 2.14. Electrons emission from the gun were accelerated by electric field to 20 kV. Electrons pass both of condenser and objective lenses, and then through a set of scan coils and an aperture. Electrons pass both of condenser and objective lenses, and then through a set of scan coils and an aperture. A scan is concurrently produced on a computer screen. Detects electrons emitted from the specimen, And expand and the signal will be used to create the image.

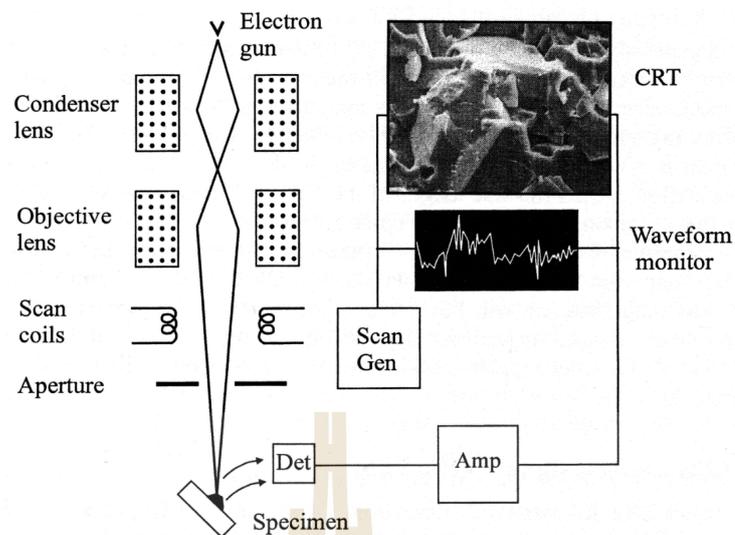

Figure 2.14 Components of the SEM.

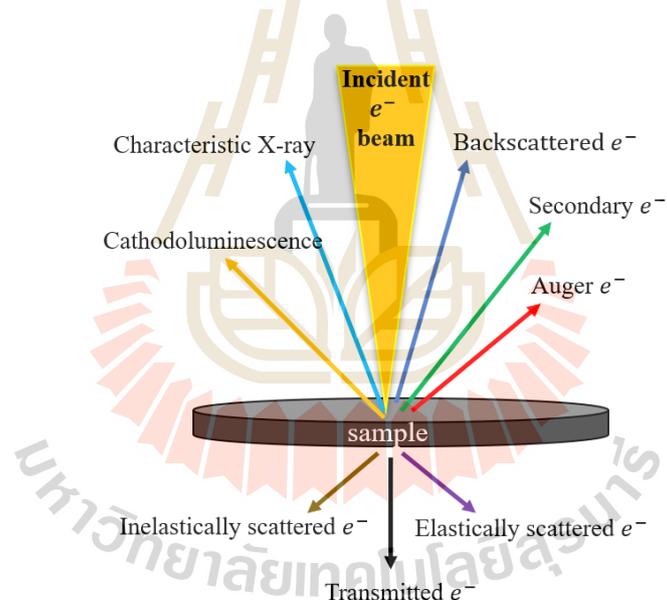

Figure 2.15 Illustration of the electron-matter interaction depicting its different-products.

Energy Dispersive X-ray Spectrometer (EDX) is an analytical technique used for the analysis of the composition or chemical properties of a sample.

2.2.4 Thermogravimetric Analysis (TGA)

Thermogravimetric Analysis (TGA) measures about weight and mass change and the rate of weight change depend on different of temperature, time and conditions. Then this measurements are used to determine the composition of materials and to predict the thermal stability. This technique can identify material loss or weight gain due to absorption/desorption of volatiles, decomposition, oxidation and reduction.

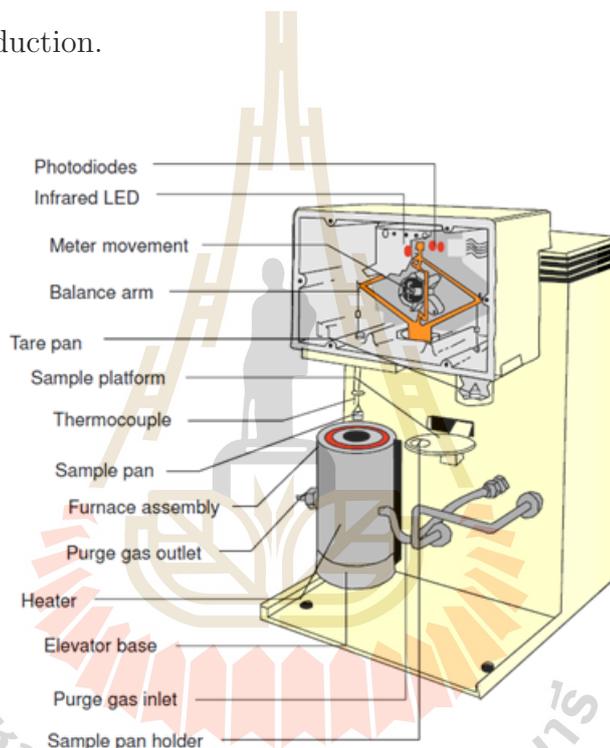

Figure 2.16 Components of the TGA.

Mechanisms of weight change in TGA. The difference weight was result of the consist of decomposition that came from the breaking apart of chemical bonds, evaporation from the loss of volatiles with elevated temperature and reduction from interaction of sample to a reducing atmosphere(hydrogen, ammonia, etc.). And for Weight Gain consist of oxidation from interaction of the sample with an oxidizing atmosphere and absorption. All of these are kinetic processes (i.e. there is a rate at which they occur).

2.2.5 X-ray absorption spectroscopy (XAS)

X-rays are ionizing radiation, can be performed at the synchrotron radiation factory, which produces intense and adjustable X-rays. Then they have energy enough to drive the core level of electrons from atoms. And each core level of each element has a different energy, so if X-ray absorption is in the form of energy, the function spectrum of any atom is similar to the X-ray absorption spectrum. The figure 2.17 shows Mass Attenuation Coefficients for different elements from the lower energy photons of the spectrum. The energy is almost totally absorbed by surrounding tissues, rendering K-edge imaging using iodine contrast agents. The absorption coefficient (μ) depends strongly on X-ray energy (E) and atomic number (Z), the density (ρ) and atomic mass (A) follow in equation 2.3. Absorption coefficient (μ) there was a sudden jump (Absorption edge) which occurs at the energy characteristics of the element.

$$\mu \approx \frac{\rho Z^4}{AE^3} \quad (2.3)$$

From the principle of X-ray radiation as above. X-ray absorption spectroscopy (XAS) is one of the techniques used to use X-ray radiation to determine the local geometric and/or electronic structure of material. The sample can be in a gas-phase solution or a solid. The XAS data is achieved by regulating the photon energy by using a monochromator crystal, to a energy range of core electrons can be excited (0.1–100 keV, 16–16,022 J).

An X-ray is absorbed by an atom when the energy of the X-ray is transferred to a core-level electron (K, L, or M shell) which is ejected from the atom (shown in figure 2.18). The atom is left in an excited state with an empty electronic level (a core hole). Any excess energy from the X-ray is given to the ejected photoelectron. The X-ray absorption spectroscopy measurement the energy dependence of the

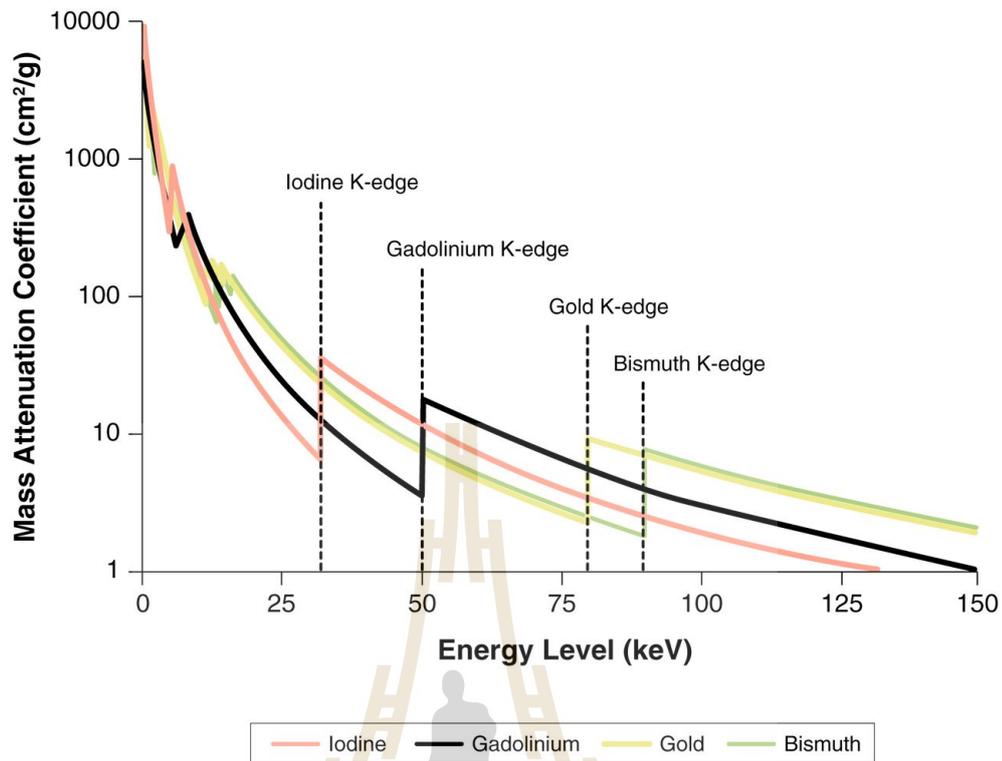

Figure 2.17 Mass Attenuation Coefficients for Iodide, Gadolinium, Gold, and Bismuth at Different Photon Energies (Danad et al., 2015).

X-ray absorption coefficient $\mu(E)$ at and above the absorption edge of selected element And $\mu(E)$ can be measured two ways:

Transmission mode: The absorption is measured directly by measuring what is transmitted through the sample:

$$I = I_0 e^{-\mu(E)t} \quad (2.4)$$

$$\mu(E)t = \ln(I_0/I) \quad (2.5)$$

where I_0 is the intensity of the incoming X-ray beam, I is the intensity of the beam after pass through the sample, and t is the thickness of the sample, is the definition of absorption coefficient, as shown in figure 2.19 and 2.20.

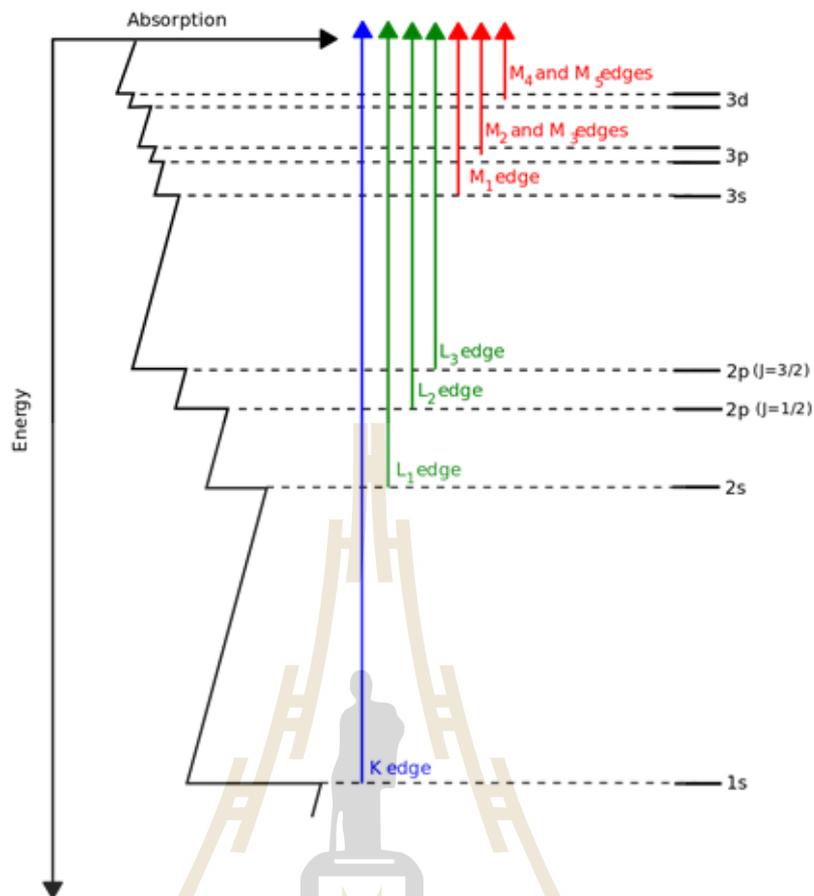

Figure 2.18 Illustrative X-ray absorption spectrum of an transition metal atom.

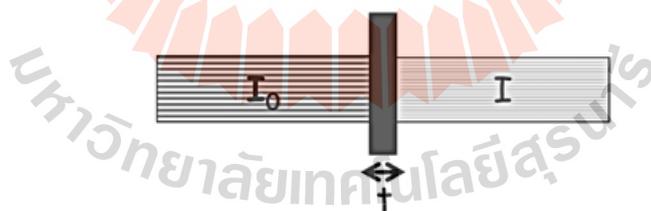

Figure 2.19 Schematic view of X-ray absorption measurement in transmission mode.

Fluorescence mode: We measured in this mode The re-filling the deep core hole is detected. Typically, the fluorescent X-ray is measured:

$$\mu(E) \sim I_F/I_0 \quad (2.6)$$

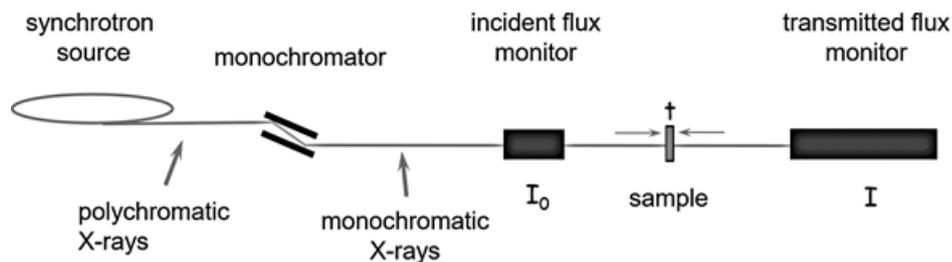

Figure 2.20 The schematic of the Absorption Coefficient μ .

DATA ANALYSIS

The spectrum signal of XAS consist of two techniques;

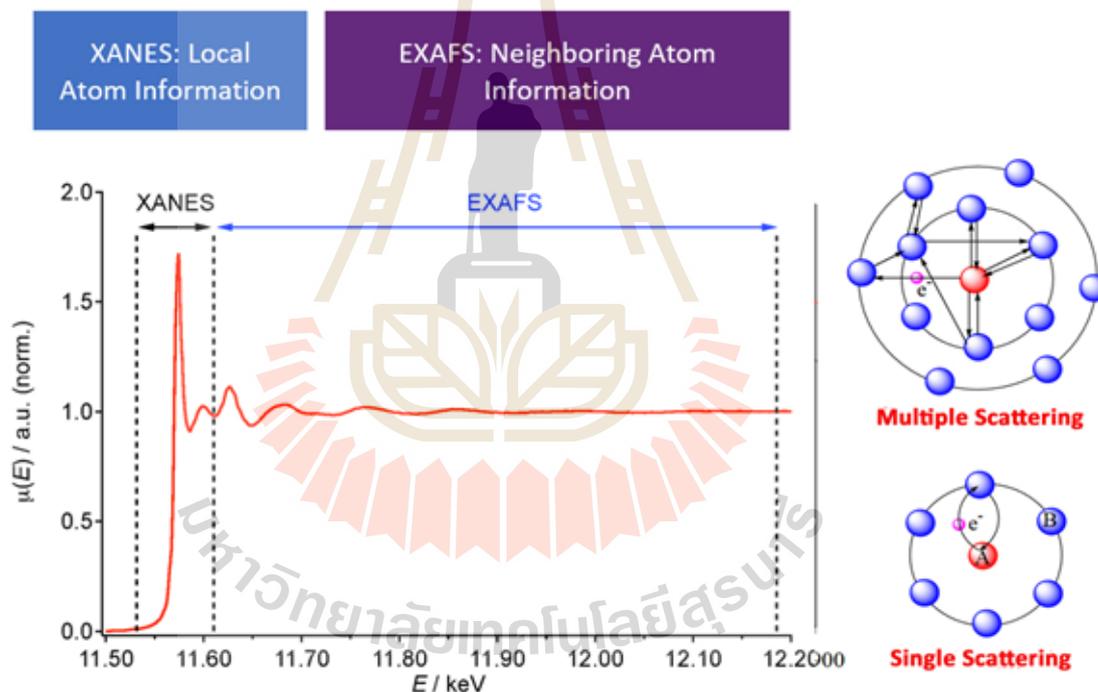

Figure 2.21 Two main regions found on a spectrum generated by XAS data. (Inc, 2018).

1. XANES (X-ray Absorption Near Edge Structure)

XANE is region of X-ray absorption spectrum within 50 eV of the absorption edge. Many edges of many elements show significant edge shifts (binding energy shifts) with oxidation state. And XANES is a strongly sensitive to the

chemistry (formal oxidation state and geometry) of the absorbing atom, it's consisted of the region of;

1.1.Pre-edge region, the transition features caused by electronic transitions to empty bound states. Transition probability controlled by dipolar selection rules. Shown the information of local geometry around absorbing atom. Dependence on oxidation state and bonding characteristics (chemical shift)

1.2.Edge region, defines ionization threshold to continuum states. The position of edge dependence on oxidation states (chemical shift), main edge shifts to higher energy with increased oxidation state. (as much as 5 eV per one-unit change).

1.3.XANES region, the transition feature dominated by multiple-scattering resonances of the photoelectrons ejected at low kinetic energy. Large scattering cross section. It's represents atomic position of neighbors or interatomic distances and bond angles. Multiple scattering dominates but ab initio calculations providing accessible insight (e.g. FEFF8)

2. EXAFS (Extended X-Ray Absorption Fine Structure)

XAS is a type of absorption spectroscopy from a core initial state with a well-defined symmetry therefore the quantum mechanical selection rules select the symmetry of the final states in the continuum which usually are mixture of multiple components. The most intense features are due to electric dipole allowed transitions (i.e. $\Delta l = \pm 1$) to unoccupied final states. For example, the most intense features of a K-edge are due to core transitions from 1s p-like final states, while the most intense features of the L₃-edge are due to 2p d-like final states. XAS methodology can be broadly divided into four experimental categories that can give complementary results to each other: metal K-edge, metal L-edge, ligand K-edge, and EXAFS.

The information of FEFF requires certain information to make its calculation.

Atomic coordinates FEFF performs its calculation on a cluster of atoms and so requires a list of Cartesian coordinates. The absorber does not need to be at (0, 0, 0).

Potential assignments Each atom is assigned a potential index along with its coordinates. This is how FEFF knows what kind of atom is at each position. Typically, each atomic species or each crystallographic position is assigned a potential.

Other parameters FEFF also needs to know which edge is to be computed (i.e., K, LIII, and so on). Another common parameter is RMAX, which limits the radial extent of the calculation. XANES calculations using FEFF8 usually require a few additional parameters.

FEFF calculation program

FEFF is an automated program for ab initio multiple scattering calculations of X-ray Absorption Fine Structure (XAFS), X-ray Absorption Near-Edge Structure (XANES) and various other spectra for clusters of atoms. The code yields scattering amplitudes and phases used in many modern XAFS analysis codes, as well as various other properties. There are steps to do as follows.

1. A FEFF input file
2. Using Atoms to prepare the FEFF input file.
3. Preparing the FEFF input file for non-crystalline materials.
4. Running FEFF
5. FEFF's output files writes several output files:

'misc.dat' General information about the potentials.

'paths.dat' Textual descriptions of all path geometries considered in the calculation.

'files.dat' A list of all path files written by FEFF.

'phase.bin' Binary file containing the data needed to compute the path files

'feffNNNN.dat' The files containing the path data. The 1st path is in 'feff0001.dat', the 2nd in 'feff0002.dat' and so on.

FEFF8 writes several additional files containing partial electronic densities of state as well as other binary data and a file called 'feff.bin' containing all 'feffNNNN.dat' files. Finally the result from FEFF can be calculated the ratio of structure in compound by ATHENA program.

2.2.6 X-ray photoelectron spectroscopy (XPS)

In X-ray photoelectron spectroscopy (XPS) is surface analytical techniques. The principle of XPS is an incident X-ray photon interacts with a core electron in a solid, gases or liquids by the photoelectric effect. The result of incident X-ray is excited electron from the atom to surrounding material. Wherewith these core electrons in an electronic environment is unique, depending on the species of atoms, electrons prefer XPS provides detailed procedures for monitoring the composition

of materials. The required environment for detecting these electrons are composed of an X-ray source, a sample and an electron detector. And high vacuum for increase the free path of electrons and the probability of detection, thus they are need to performed in ultra-high vacuum.

The X-ray energy from source hit on the surface and X-ray photon of energy were incidents. This energy will be absorbed by the binding energy of the atom. After the X-ray hit, The excess energy from the X-ray source used to ejected electron from the atom was detected in an analyzer. We can calculate the binding energy of electron by equation 2.7.

$$E_B = hv - E_k - \phi_{analyser} \quad (2.7)$$

where $\phi_{analyser}$ is the work function of the electron analyser, not the species in question. This means that any detected electrons provide a specific fingerprint of the atomic species in the near surface region. The chemical shifts are the slight variations of binding energy, refer to the chemical environment of atoms in the near surface region to be determined. However, due to varying x-ray absorption probabilities of different states the picture is slightly more complex. This process is shown schematically figure 2.24. A typical XPS spectrum is illustrated below. The spectrum shows a series of sharp peaks corresponding to core states of surface atoms. These peaks are accompanied by inelastic loss tail features, arising from interactions before the electrons emerge from the surface, thus, reducing their energy, This feature in itself can be used to obtain chemical depth profiles of the sample. Increasing the surface specificity of XPS can be achieved by using smaller angles of incidence. Then the XPS is the one of excellent technique for qualitative and quantitative analysis of chemical compound (L. Rosenberger).

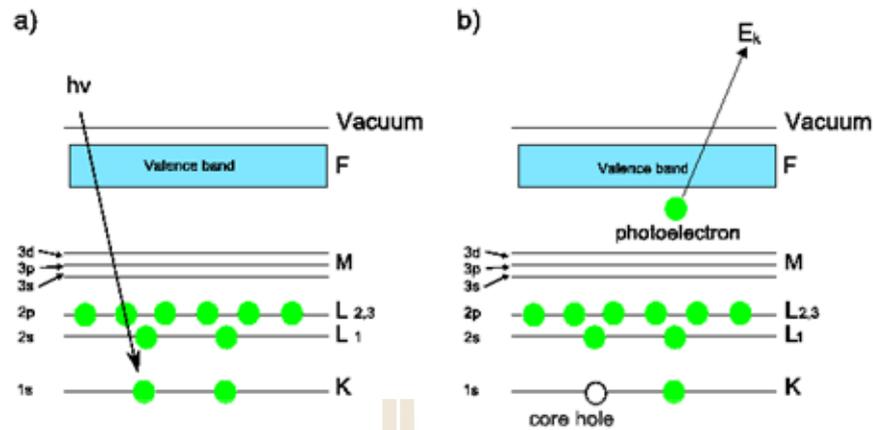

Figure 2.24 Schematic of the photoemission process in XPS. a) Incident photon energy $h\nu$ is absorbed by a core level electron. b) If $h\nu > E_k$ then the electron is emitted, and a core hole is left behind. This core hole may be filled by an electron from a higher state, causing emission of a secondary photon, or an Auger electron.

X-ray photoelectron Spectroscopy (XPS) technique used to study about elemental identification and chemical state of element, Relative composition of the constituents in the surface region. And valence band structure. We can calculate percentage of element by used equation 2.8.

$$\text{Percentage for element } X = \frac{\frac{I_x}{S_x T_x}}{\sum_{i=1}^n \frac{I_i}{S_i T_i}} \times 100 \quad (2.8)$$

where n: number of regions

I: intensity

S: sensitivity factor

T: acquisition time per data point

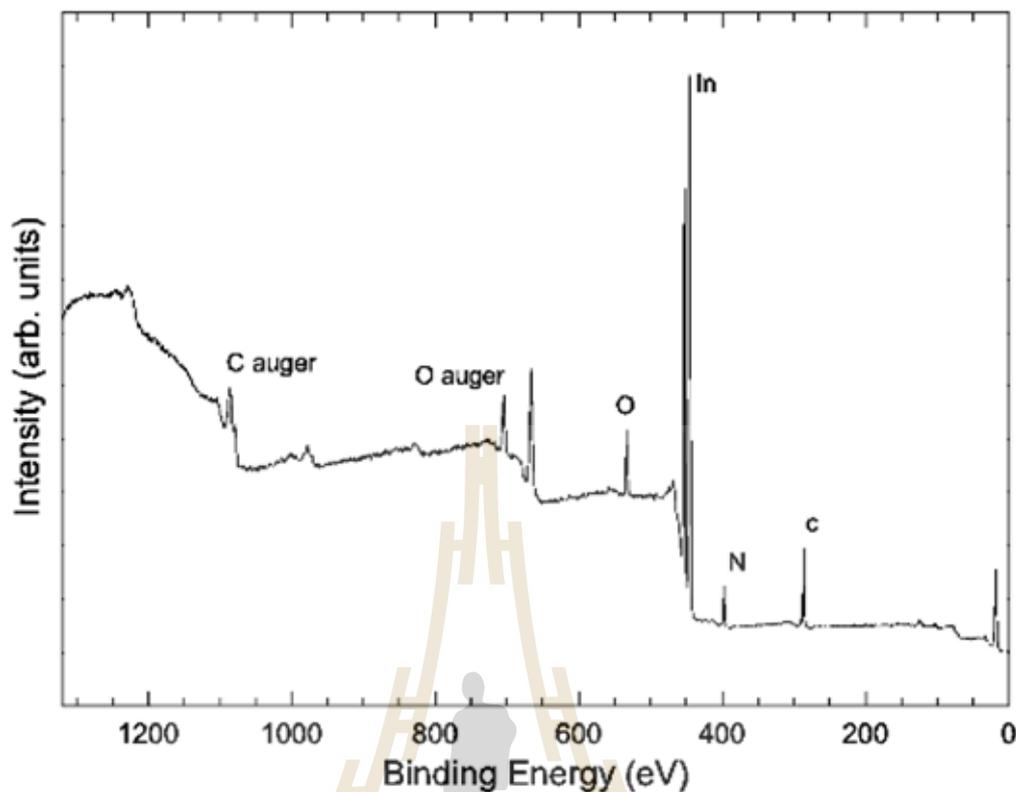

Figure 2.25 A typical XPS spectrum of an as-loaded InN sample, taken with a monochromat 1486.6 eV $Al_k - \alpha$ source. Stepped structure of the background is due to inelastic processes.

2.3 CHARACTERIZATION MEASUREMENT

2.3.1 Basic characterizing of the powder of CH_3NH_3I and $CH_3NH_3PbI_{(3-x)}Cl_x$ perovskite

1. The weight loss of the $CH_3NH_3PbI_{(3-x)}Cl_x$ compound samples is studied by Thermogravimetric/Differential Thermal Analyzer (TG-DTA).
2. The size, morphology, elemental and distribution studied by Scanning electron microscopy (SEM) and Energy Dispersive X-ray (EDX).
3. The structure of the $CH_3NH_3PbI_{(3-x)}Cl_x$ compound samples is evaluated by X-ray Diffraction (XRD) and Infrared Spectroscopy (IR).

Figure 2.26 Bruker D2 PHASER.

X-ray diffraction is a standard technique for material characterization to obtain micro structural information for crystalline and non-crystalline materials. This non-destructive method could provide information's such as crystal structure, lattice parameter, crystal size, composition etc. which are useful for ceramics, metal alloys, semiconductors, polymer, nano-materials research. The X-ray diffraction is a standard technique for material characterization used by Bruker D2 PHASER. X-ray source is Ceramic Cu X-ray tube in 30 kV/ 10 mA.

Figure 2.27 FT-IR Microscope Bruker Tensor 27 with Hyperion 3000.

Bruker “Tensor 27” spectrometer with “Hyperion 3000” FT-IR microscope using a Single element MCT detector, 64*64 elements FPA detector, 20x ATR (Ge crystal) objective, 20x Ref-objective with macro-ATR-stage (600600 m FoV),GIR-objective,16x transmission and reflection objective, “KnowItAll” software package for spectrum analysis, “OPUS” software package.

2.3.2 The oxidation state of various transitions and rare earth metal ions are evaluated by X-ray Absorption Spectroscopy (XAS) and X-ray Photoelectron Spectroscopy (XPS)

1. XPS MEASUREMENTS.

XPS measurements were performed using a PHI5000 Versa probe II (ULVAC-PHI, Japan) equipped with a hemispherical electron energy analyzer at the SUT-NANOTEC-SLRI joint research facility, Synchrotron Light Research Institute (SLRI). A monochromatic Al K X-ray gun (1486.6 eV) was used as the excitation source. The XPS survey scans were collected from 0-1400 eV with pass energy 117.40 eV and energy step 1.0 eV. High resolutions XPS spectra were collected with pass energy 46.95 eV and energy step 0.05 eV for probing elements of interested. The XPS spectra were analyzed by PHI Multipak XPS software. The binding energy of all XPS spectra were calibrated with the C1s peak at 284.8 eV. The Sherly background subtraction and combinations of Gaussian-Lorentzian line shape were applied for peak deconvolution.

2. XAS MEASUREMENTS.

The XAS spectra in this thesis were obtained at the XAS facility (BL-5.2) of Siam Photon Laboratory, Synchrotron Light Research Institute, Nakhon

Ratchasima, Thailand, with the storage ring running at 1.2 GeV and beam current of 70-140 mA during the measurement. XAS measurement was performed in the transition mode using Ge (220) monochromator for I L₃-edge, Pb M₅-edge and the fluorescence mode using InSb(111) monochromator for Cl K-edge XAS spectra. And used Kapton tape and PP plastic poly bag to pack the samples for X-ray transparent.

Preparing powder sample for TM-XAS.

Figure 2.28 FT-IR Microscope Bruker Tensor 27 with Hyperion 3000.

1. Put some sample in a small agate mortar, use pestle to grind the sample into very fine powder.
2. Cut a piece of hard paper or plastic sheet to make a sample frame as shown.
3. Place a piece of thin Kapton (Polyimide) tape on the frame, sticky side up. Kapton tape should be thinner than.
4. Use sample in the mortar, weigh the right amount of the sample that equals the optimal mass, apply the sample over the sticky window area evenly and homogeneously, make sure there is no “pinhole” in the sample area. Cover the sample area with a Kapton tape.

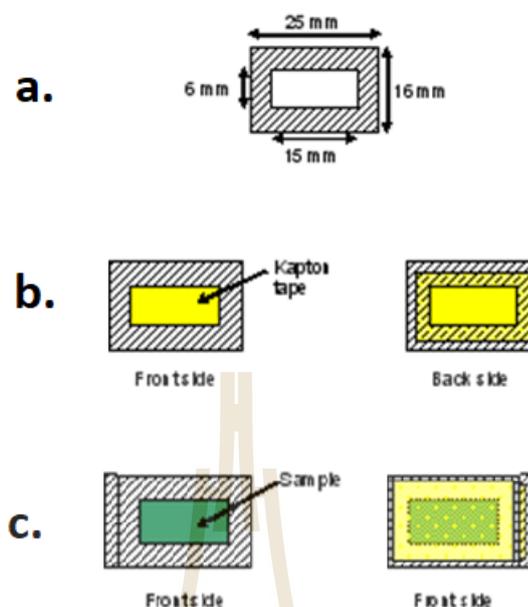

Figure 2.29 schematic to prepared powder sample for TM-XAS.

2.3.3 Population/Samplings/ Location of research

1. Materials used :

- Methylamine solution 40 wt% in H_2O , CH_3NH_2 , Sigma-Aldrich
- Hydriodic acid 57 wt% distilled, 99.999% trace metals basis, HI, Aldrich
- Lead (II) chloride 99.999% trace metals basis, $PbCl_2$, Aldrich
- Acetone 99.999%, Aldrich

2. Location of research :

- Solid state chemistry Laboratory Laboratory, School of Chemistry, Institute of Science, Suranaree University of Technology, Nakhon Ratchasima, Thailand.

- The Center for Scientific and Technological Equipment, SUT.
- Synchrotron Light Research Institute (Public Organization).

3. Instrumentation :

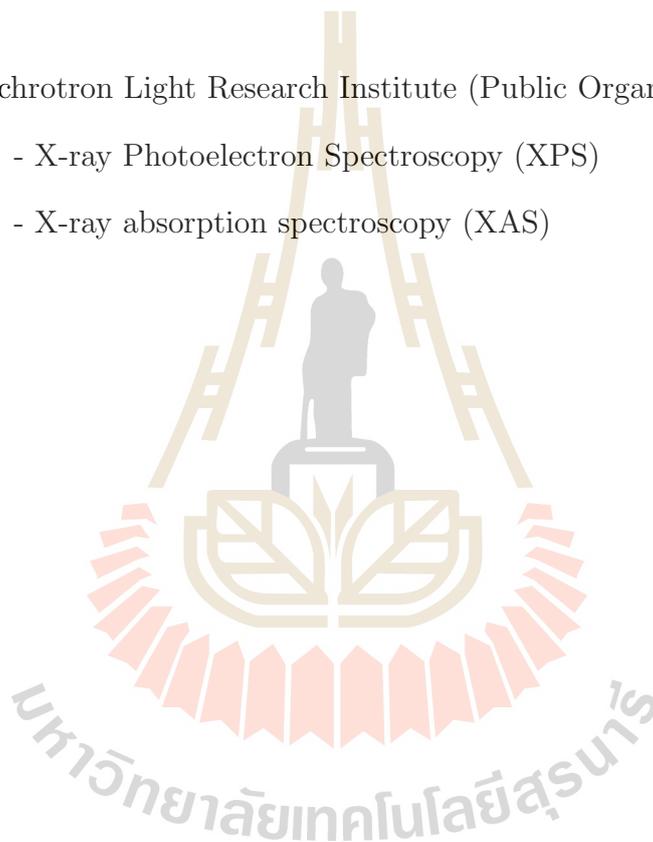

- The Center for Scientific and Technological Equipment, SUT:

- X-ray Diffraction (XRD)
- Thermogravimetric/Differential Thermal Analyzer (TG-DTA)
- Infrared Spectroscopy (IR)
- Scanning electron microscopy (SEM) and Energy Dispersive X-ray

(EDX)

- Synchrotron Light Research Institute (Public Organization):

- X-ray Photoelectron Spectroscopy (XPS)
- X-ray absorption spectroscopy (XAS)

CHAPTER III

STANDARD CHARACTERIZATION

RESULTS AND DISCUSSIONS

The formation of $\text{CH}_3\text{NH}_3\text{I}$, $\text{CH}_3\text{NH}_3\text{PbI}_3$ and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ was confirmed by XRD, IR, XPS and XAS for investigated on the surface and interface electronic structure due to this properties can provide important of information about the physical mechanism of this kind of perovskite, It's help to improve the PCE and stability.

3.1 METHYLAMMONIUM IODIDE

Methylammonium iodide are organic group as a component of perovskite crystalline solar cell. And the iodide is the most commonly used. In this research we changed a solvent for reduced I_2 from Sero-gel in Sol-gel method. And we found a new solvent for reduces I_2 can decreased times to prepared methylammonium iodide powder 4 times from the former solvent. Then first of all, we use X-ray diffraction (XRD) for investigated crystalline of $\text{CH}_3\text{NH}_3\text{I}$ powder, The XRD measurement was performed in ambient condition. The X-ray diffraction patterns were obtained using a Bruker instrument Cu K beam ($\lambda = 1.54 \text{ \AA}$). As shown in the XRD pattern in figure 3.1 shown the pattern of $\text{CH}_3\text{NH}_3\text{I}$ (MAI) dissolved in diethyl ether after that precipitation in N, N-dimethylformamide (DMF), $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar (AC_Ar) and $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone (AC_Air). The typically indexed the peaks of a orthorhombic lattice in all

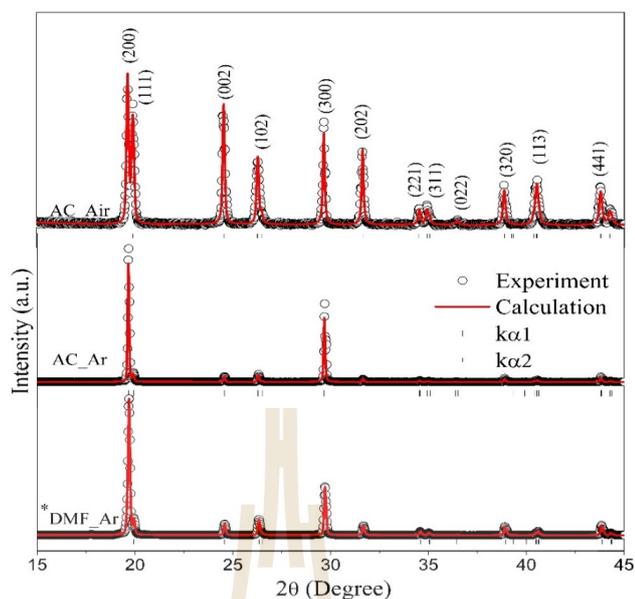

Figure 3.1 X-ray diffraction pattern of $\text{CH}_3\text{NH}_3\text{I}$ powder in different condition and the most obvious pattern of orthorhombic lattice is clearly in $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone (AC_Air).

of samples. The both of $\text{CH}_3\text{NH}_3\text{I}$ (MAI) dissolved in diethyl ether after that precipitation in N,N-dimethylformamide (DMF) and washed by acetone and dry in Ar (Ar) have a similar of intensity of peak. We investigated organic group of $\text{CH}_3\text{NH}_3\text{I}$ from the figure 3.2 shown the Infrared absorption data functional groups of $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar (AC_Ar) and $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone (AC_Air). The absorption cited are associated with stretching and bending vibrations of organic group in $\text{CH}_3\text{NH}_3\text{I}$. The peaks in IR spectrum in the region $1400, 1480, 1700 \text{ cm}^{-1}$ and $2700, 2950, 3100 \text{ cm}^{-1}$ are sharp, strong peak of C-H bending and stretching, in the region $920, 1250 \text{ cm}^{-1}$ are the sharp, strong peak of C-N stretching, in the region 1550 cm^{-1} is the medium, broad peak of N-H bending. And in the region 3500 cm^{-1} is weak, broad peak of O-H stretching absorption of alcohol. But O-H stretching just found in $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone (AC_Air).it came from H_2O due to MAI are sensitive of moisture and in this

position to observe the force vibration between O-H weaker than N-H. then this peak is weak and broad more than the vibration of peak of N-H. and in a long time when we keep the MAI in dry cabinet. we found the $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in air, decompose quickly than $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in 60°C Ar.

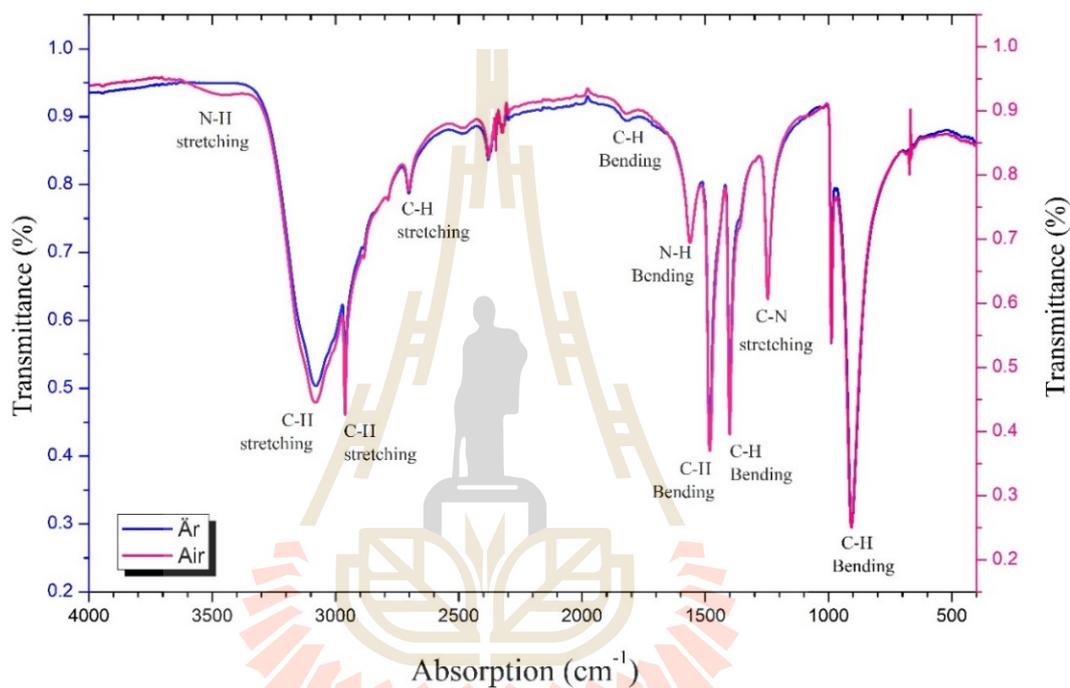

Figure 3.2 The Infrared absorption data functional groups of $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar (AC_Ar) and $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone (AC_Air).

The data of XPS in figure 3.3 shows spectra from a PHI5000 Versa probe II (ULVAC-PHI, Japan) equipped with a hemispherical electron energy analyzer, the excitation source used by a monochromatic Al $K\alpha$ X-ray gun (1486.6 eV). The core level of spectra in C1s to consist of two peaks position follow at table 3.1 and XPS FWHMs at table 3.2. The core level is position 284.93, ~ 286.43 and ~ 285 , ~ 286.55 in MAI_(AC_Ar) and MAI_(AC_Air), respectively. The core level is position ~ 284.93 eV and ~ 285 referred to C-H and C-C bonding. And the core level

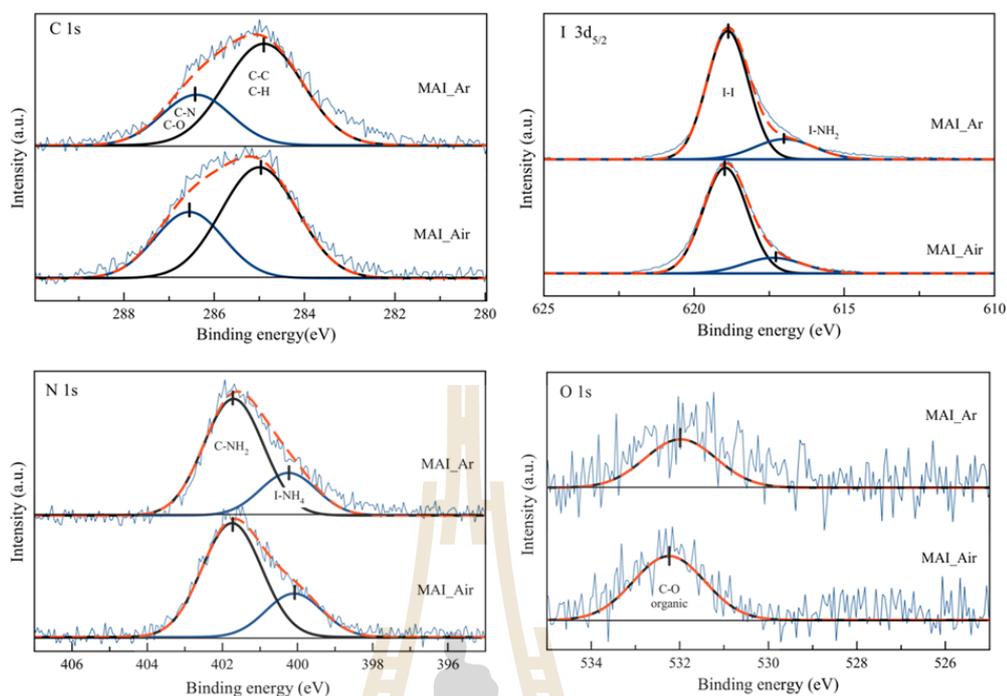

Figure 3.3 The data of XPS of $\text{CH}_3\text{NH}_3\text{I}$ powder.

Table 3.1 XPS core level positions, elemental bonding and percent of element in compound of $\text{CH}_3\text{NH}_3\text{I}$.

Samples	Core level center (eV)						
	C 1s		I 3d5		N 1s		O 1s
	1	2	1	2	1	2	1
MAI_(AC_Ar)	286.43	284.93	618.88	616.99	401.70	400.24	531.98
<i>Bonding</i>	C-C	C-N	I-I	I-NH ₄	I-NH ₄	C-NH ₄	C-O
<i>Percent of elements</i>	54.31		21.16		22.55		1.97
MAI_(AC_Air)	286.55	285	619	617.36	401.74	400.10	532.24
<i>Bonding</i>	C-C	C-N	I-I	I-NH ₄	I-NH ₄	C-NH ₄	C-O
<i>Percent of elements</i>	53.67		20.16		22.95		3.22

is position ~ 286.43 eV and ~ 286.55 eV referred to C-N and C-O bonding. They are overlays due to energy bonding of element is very close (Li et al.,2015).

Table 3.2 XPS FWHMs of element in compound of $\text{CH}_3\text{NH}_3\text{I}$ in different condition to dry.

Samples	Core level center (eV)						
	C 1s		I 3d5		N 1s		O 1s
	1	2	1	2	1	2	1
MAI_(AC_Ar)	1.8	2.04	2	2.33	1.87	1.77	1.89
MAI_(AC_Air)	1.8	2	2	2.33	1.87	1.77	1.9

For the evident of XPS data, the $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar (AC_Ar) we found the peak of carbon for C-H and C-C bonding has a high ratio than $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone after that dry in air (AC_Air). And the $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Air (AC_Air) the peak of C-N and C-O bonding has a high ratio than $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone after that dry in Ar (AC_Ar). That can refer to the compound of $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Air (AC_Air) have a contaminate with Oxygen or moisture than $\text{CH}_3\text{NH}_3\text{I}$ washed by acetone and dry in Ar (AC_Ar). And the ratio of oxygen in AC_Air is more than AC_Ar then $\text{CH}_3\text{NH}_3\text{I}$ (AC_Ar) is lower contaminate than $\text{CH}_3\text{NH}_3\text{I}$ dry in air (AC_Air). The data analysis clearly about the percentage for elemental of $\text{CH}_3\text{NH}_3\text{I}$ can calculated follow equation below and shown the percentage of element in table 3.1.

The XANES analysis of MAI from the figure 3.4 I L_3 -edge spectral feature are sensitive to the local of I. The spectral feature of MAI wash by acetone and dry in air, dry in Ar and recrystallized in DMF shown the local geometry, charge state and orbital occupancy are same. And we used ATHENA program to fitting

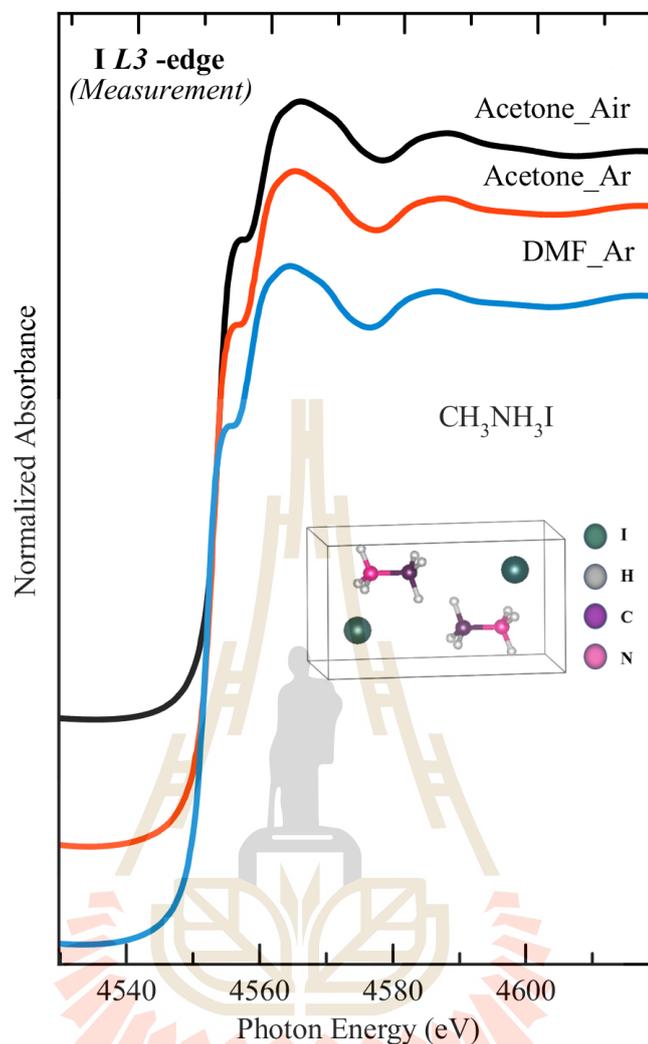

Figure 3.4 Normalized L₃ edge XANES spectra of Iodide for MAI wash by acetone and dry in air, dry in Ar and recrystallized in DMF.

combination standard (DMF) spectra to sample spectra. We found MAI wash by acetone and dry in air (Ace_Air) have constrain the variable weight 0.814 like a standard and MAI wash by acetone and dry in Ar (Ace_Ar) have constrain the variable weight 0.186 like a standard. Then We choose CH₃NH₃I (MAI), It reduced I₂ by Acetone and dry in Ar replace to MAI in DMF for as the precursor of CH₃NH₃PbI₃ because they are stable in H₂O and lower contamination than MAI wash by acetone and dry in air.

3.2 METHYLAMMONIUM LEAD IODIDES

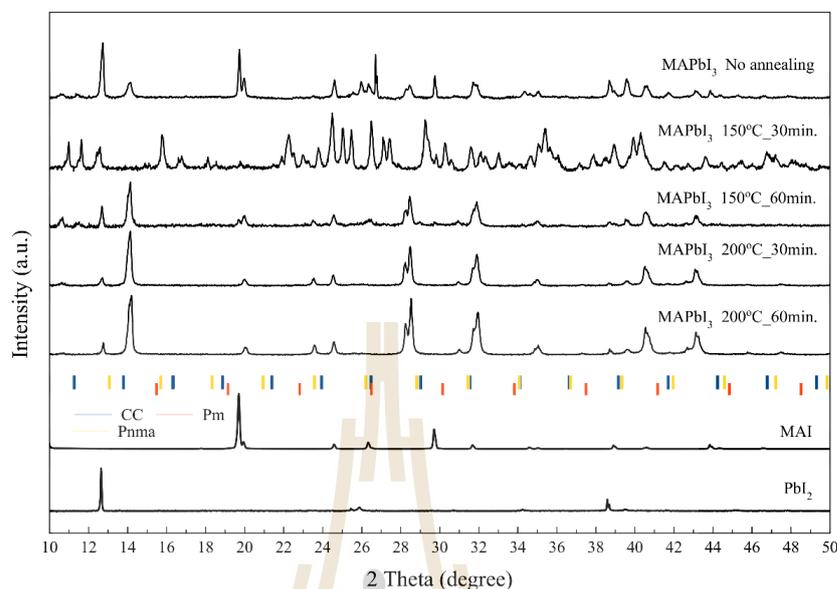

Figure 3.5 X-ray diffraction pattern of $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder.

The first of all we characterized $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder by used XRD. And from the figure 3.5 shown the pattern of X-ray diffraction of perovskite powder made from a 1:1 molar mixture of PbI_2 and MAI in acetone and dry in Ar. Shown the typical peaks at 14.10° , 23.47° , 28.42° , 30.89° correspond to (110), (211), (220), (213) of the tetragonal phase perovskite, respectively. And figure 3.12 shown the spectral feature of I L_3 -edge spectra feature are sensitive to the local of I. The spectral feature of all sample of perovskite is same about oxidation number and shape of molecules. Then the $\text{CH}_3\text{NH}_3\text{I}$ wash by acetone and dry in Ar. Can used to the precursor for synthesis perovskite similar to $\text{CH}_3\text{NH}_3\text{I}$ dissolved in diethyl ether after that precipitation in N, N-dimethylformamide and dry in Ar, which takes longer 4times in a new solution for wash.

We calculated particles size of the $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder surface on annealing at 200°C in 30 minutes and 60 minutes by Image J program. In figure 3.7 we found the particle size of $\text{CH}_3\text{NH}_3\text{PbI}_3$ on annealing at 200°C in 30 minutes has

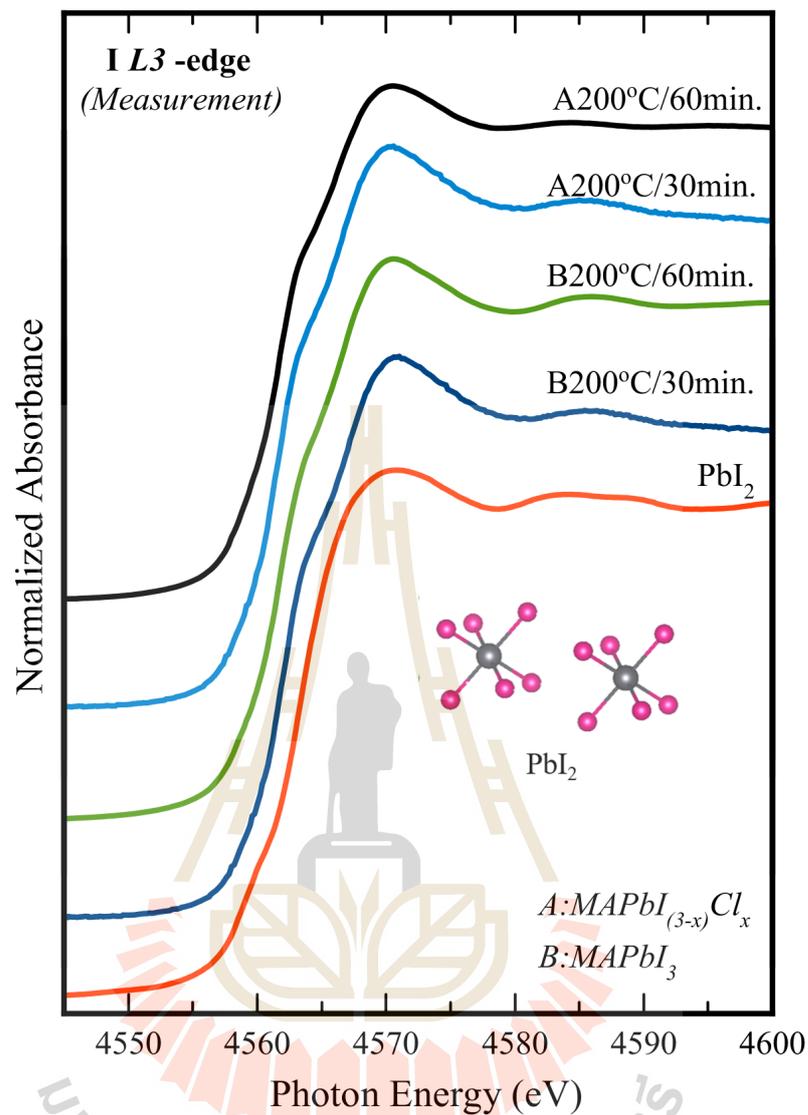

Figure 3.6 Normalized L_3 -edge XANES spectra of Iodide for $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder compared with PbI_2 (precursor).

52.02 nm and $\text{CH}_3\text{NH}_3\text{PbI}_3$ on annealing at 200°C in 60 minutes has 47.80 nm. And on annealing in 60 minutes with similar size more than 30 minutes because more time is available for nucleation and growth of the new recrystallized grains.

The MAI precursors from different solvents were used to synthesis hybrid perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$ powders by solid state method with varying conditions. The characterizations by X-ray Diffraction (XRD), Infrared Spectroscopy (IR), X-

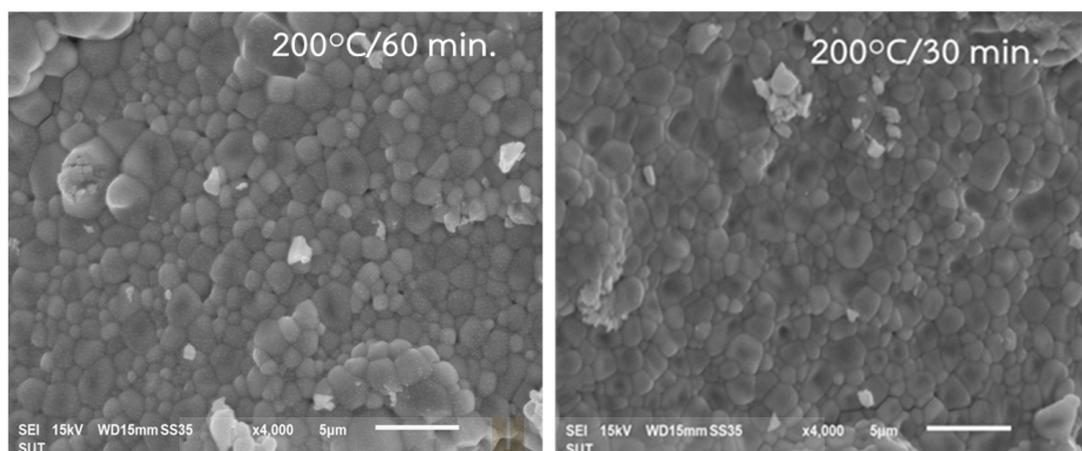

Figure 3.7 SEM image of the $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder surface on annealing at 200°C in 30 minutes and 60 minutes.

ray photoelectron spectroscopy (XPS) and X-ray absorption spectroscopy (XAS) shown that the characteristic quality of hybrid perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$ powders from acetone and DMF are comparable thus confirm the effective of the new preparation route. From the result as I previously mentioned of $\text{CH}_3\text{NH}_3\text{I}$ power precursors from different solvents were used to synthesis hybrid perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$.

3.3 METHYLAMMONIUM LEAD IODIDE CHLORIDE

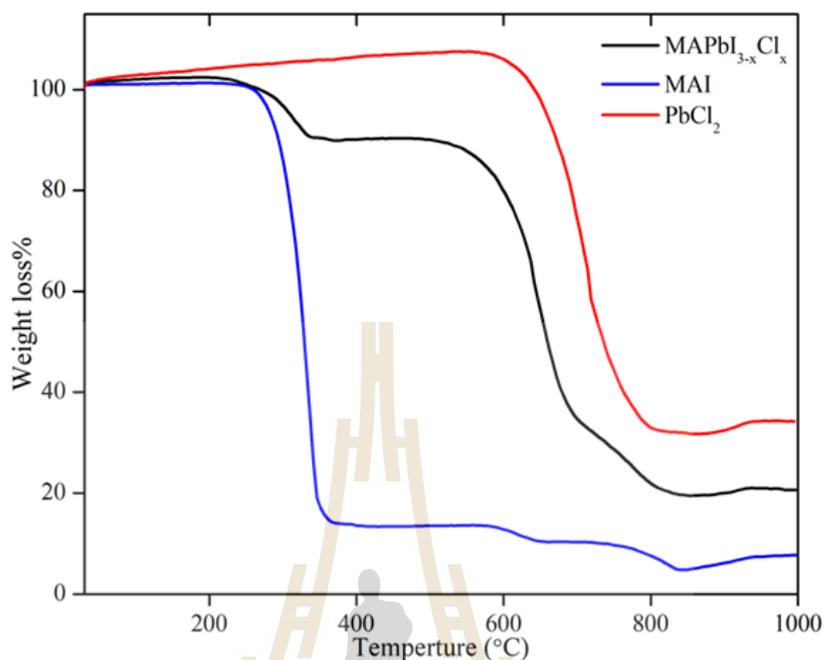

Figure 3.8 TGA curves for $\text{CH}_3\text{NH}_3\text{I}$, PbCl_2 and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powders.

Thermogravimetry analysis (TGA) is usually used in order to determine the suitable temperature to be used for annealing $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powders. From the figure 3.8 when we increase temperature around 250°C organic group (MAI) are loss from 100% weight to 18 % weight, We should not annealing at 250°C the because MAI will be decomposed. Then, we choose rang of temperature to annealing form 100 to 250°C for my experiment.

From the figure 3.9 the pattern of X-ray diffraction shows pattern of XRD from precursor in (MAI: PbCl_2) difference molar of ratio. we found the structure of perovskite is clearly in molar ratio of precursor 1:1. And in precursor MAI: PbCl_2 molar ratio of 2:1 and 3:1 have many of phase so it's impurities more than 1:1. Then we focus only molar ratio of precursor 1:1 for study structure and properties of perovskite.

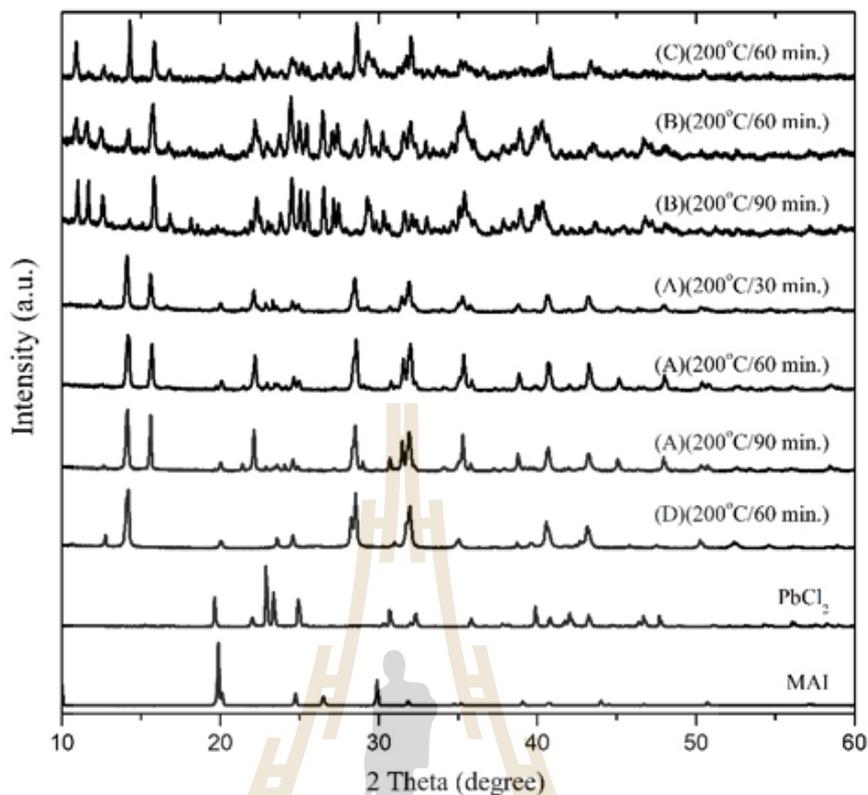

Figure 3.9 Pattern of XRD from precursor (MAI: PbCl₂) in difference molar of ratio 1:1(A), 2:1(B), 3:1(C) and MAPbI₃ (D).

From the figure 3.10 the pattern of X-ray diffraction shows pattern of XRD from precursor in (MAI: PbCl₂) molar of ratio 1:1 in different temperature and time we found the structure of perovskite begin to form a structure at 100°C but it's not all of powder form to perovskite structure and after we annealing at 150°C in 90 min. the structure of perovskite is clearer but has a peak intensity of CH₃NH₃Cl ; MAI higher than phase of perovskite then the crystalline of MAI more than crystalline of perovskite . At 200°C in 30, 60 and 90 min. the intensity of perovskite phase is clearly and higher than MAI. Then we will focus on this point to annealing due to the crystalline phases are mixture about perovskite phase and CH₃NH₃Cl obvious. The symbols *, + and # denote the peaks of CH₃NH₃PbI_(3-x)Cl_x perovskite, PbI₂ and CH₃NH₃Cl, respectively; the unlabeled

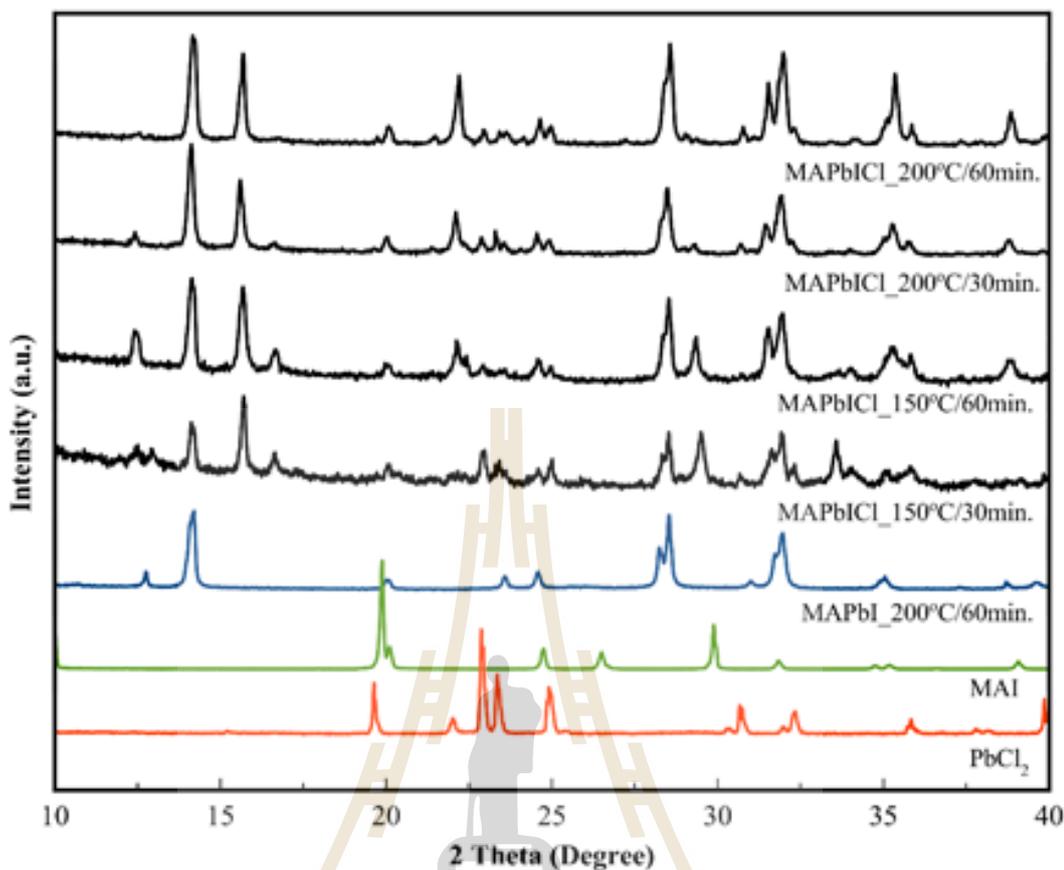

Figure 3.10 The pattern of XRD from precursor molar of ratio 1:1 (MAI: PbCl₂) in different temperatures and times compared with CH₃NH₃PbI₃.

peaks are attributed to the intermediate phase.

From the figure 3.12 shown the peak position of peak perovskite structure (peak in left-hand side) shift to higher theta and CH₃NH₃Cl (peak in right-hand side) has a shape peak, when we increase time to annealing. Shifting of peak is can refer to Cl replace to I in structure of perovskite. But the Cl anion is a different size with I anion then Cl anion is very little possibility that to replace to I anion. We will calculate the possibility of Cl replacement in I by use XAS technique for characterized the local structure of Cl atom and use FEFF program to compare ratio of CH₃NH₃PbI_(3-x)Cl_x perovskite and CH₃NH₃Cl in this material.

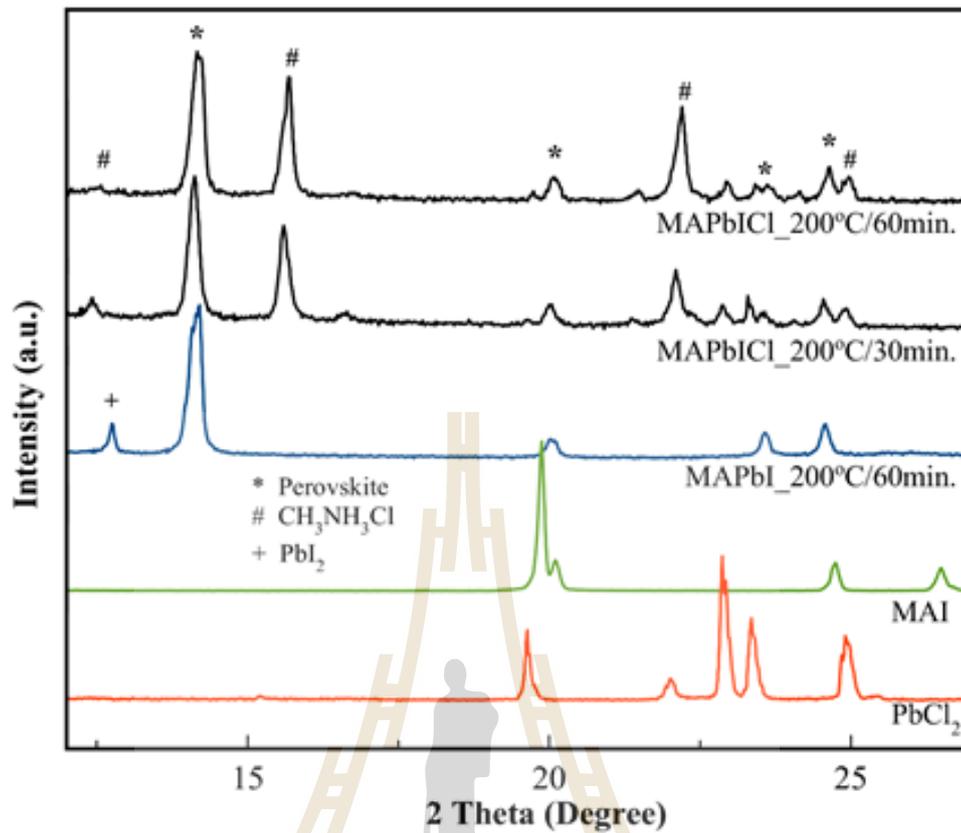

Figure 3.11 The XRD patterns for the molar ratio of precursor MAI and $PbCl_2$ is 1:1(A) annealed for 30 and 60 mins at $200^\circ C$ compared with $CH_3NH_3PbI_3$.

The possible chemical reactions involved in the perovskite formation process from precursor ($MAI: PbCl_2$) molar of ratio 3:1 (1) may involve several intermediate steps. Firstly, since the amount of CH_3NH_3I in molar is 3 times that

$200^\circ\text{C}/60$ min.	2.00	2.00	1.40	1.40	1.40	1.40	1.30	1.42

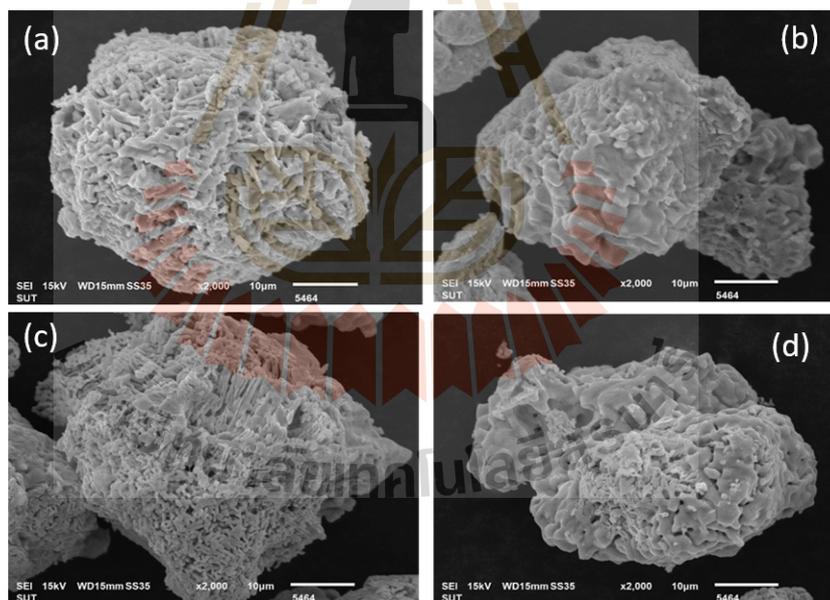

Figure 3.15 SEM image of the $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder surface on annealing at (a) 150°C in 30 minutes (b) 150°C in 60 minutes (c) 200°C in 30 minutes and (d) 200°C in 60 minutes.

The SEM image of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder in figure 3.15 shows the surface of powder not homogenous and has porous all of samples. There is a possibility that it is caused by organic salt of $\text{CH}_3\text{NH}_3\text{Cl}$ that sticks on the skin. And we measured EDX for find present of element in surface the ratio of Pb and Cl are increasing when we increase temperature and I, N and C decreasing when we increase times to annealing (figure 3.16). And shows Spectrum of energy dispersive of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder on annealing at 200°C in different times.

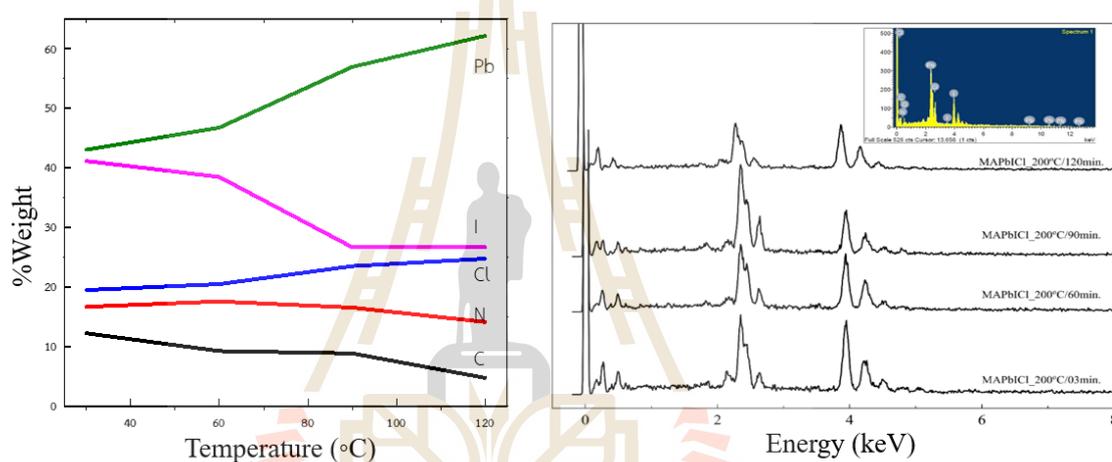

Figure 3.16 EDX trend and Spectrum of energy dispersive of the $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder surface on annealing at 200°C in different times.

The spectrum pattern of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ and $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder annealing at 200°C show in figure 3.17. The shape of spectra line is almost like to same in all of sample (difference of white line a little bit from PbI_2 precursor due to in $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ and $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder have atom of MAI). That means atom of Iodide interact with Pb has a same of lattice structure (octahedral) for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ and $\text{CH}_3\text{NH}_3\text{PbI}_3$ powder. And for normalized M_5 edge XANES spectra of Lead. The spectra feature of XANE are same of precursor because both of PbCl_2 and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ are same of lattice structure (octahe-

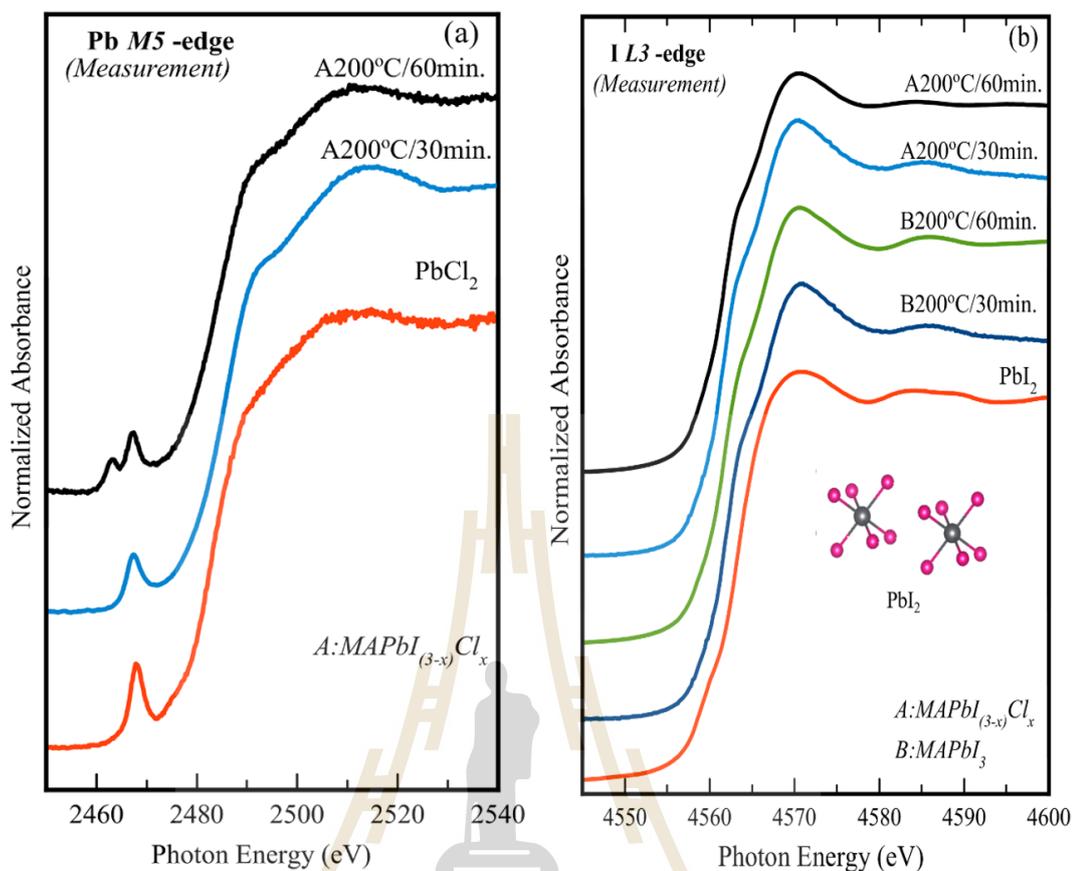

Figure 3.17 (a) Normalized L_3 edge XANES spectra of Iodide (b) Normalized M_5 edge XANES spectra of Lead for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder.

dral). It possible that PbCl_2 is result of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ decomposed or PbCl_2 is a excess reagent. The pre-edge region spectra of Lead in $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder annealing at 200°C for 60 minutes have two peak because in this condition, there are structural will be changes from octahedral structure to another type.

At the normalized K edge XANES spectra of Chloride. The feature of spectra is not similar in white line curve indicated to a neighbor atom not same. So, we will calculate the position of Cl in this powder. Although Cl is smaller atom than Lead and energy for XAS measured are nearly. Then we will be measured in fluorescent mode. The data of XAS can calculated by use spectra in rang of XANE. From the figure 3.18 shown the linear combination fit we found the

different of structure of Chloride and now we doing to calculation the ratio of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ perovskite and $\text{CH}_3\text{NH}_3\text{Cl}$ in this material by using FEFF calculation. And from the pattern of XRD in figure 3.16 shown the secondary phase of MACl , PbCl_2 or $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$. Then we will use this structure of all to calculated in FEFF XANE.

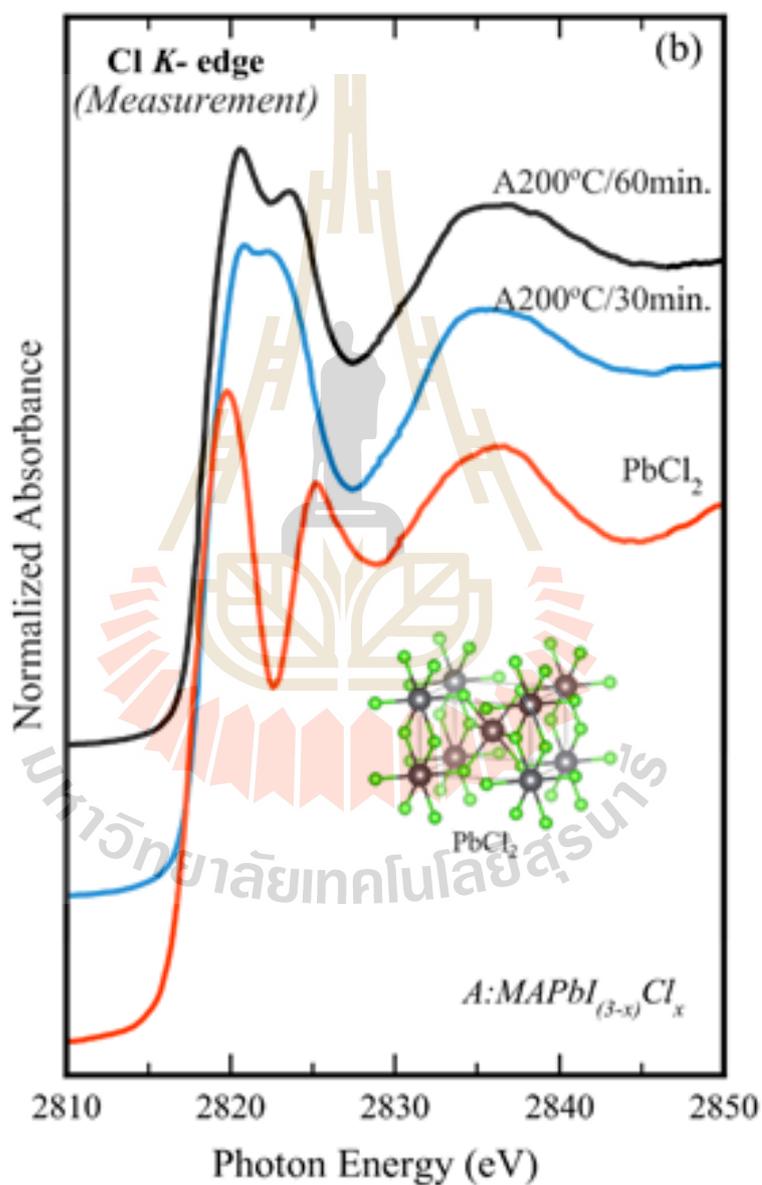

Figure 3.18 Normalized K edge XANES spectra of Chloride for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder annealing at 200°C.

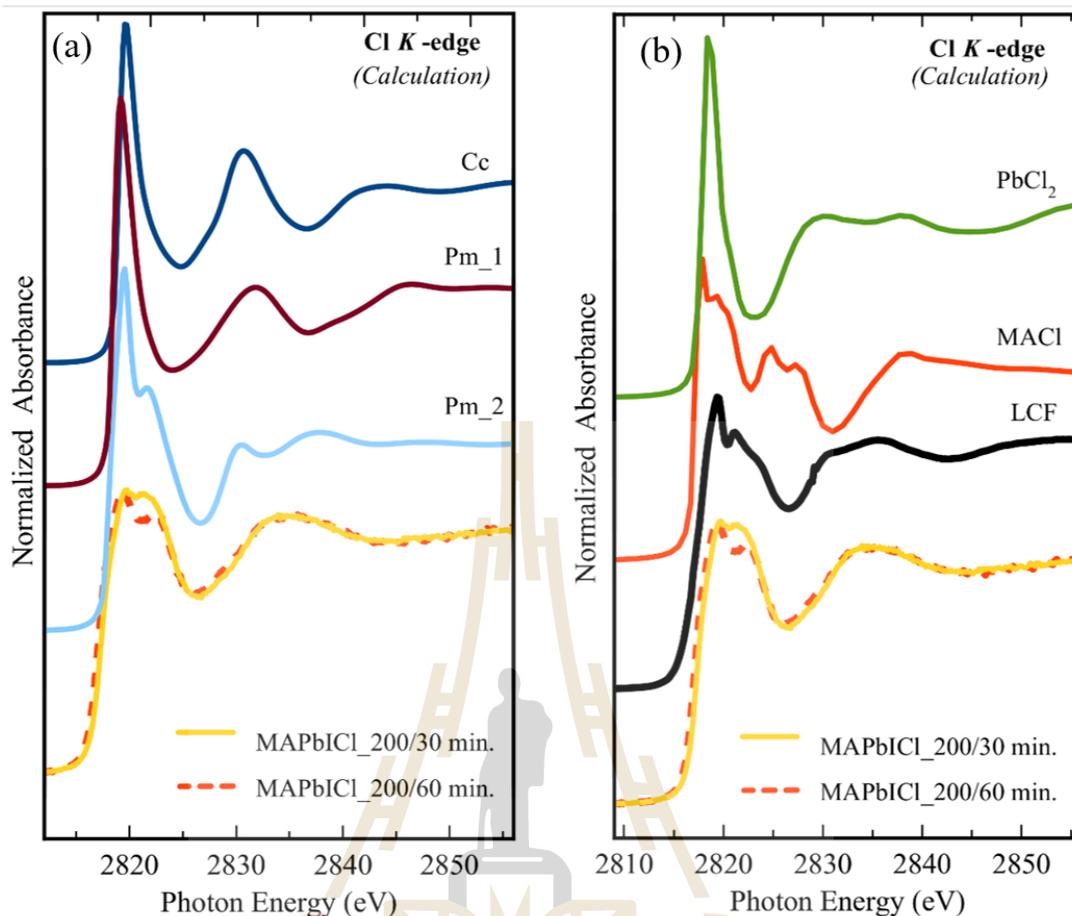

Figure 3.19 (a) Comparison of normalized K edge XANES spectra of Chloride for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder annealing at 200°C with a structure of perovskite for FEFF XANE calculation. (b) Linear combination fit of normalized K edge XANES spectra of Chloride for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder annealing at 200°C with PbCl_2 , MACl from the calculation.

The figure 3.19(a) shows the possibility of perovskite structure and we choose this structure for FEFF XANE calculation. We compared normalized K edge XANES spectra of Chloride for $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powder annealing at 200°C with the structure of perovskite by FEFF XANE calculation. And calculate the ratio of impossible structure in table 3.6 from linear combination fit in ATHENA program. The information from table 3.6 is just a trend of perovskite

structure because we used a data base of XRD of structure from the material project. We calculated XANES spectra of Chloride in linear combination fit in the range of -10 to 60 from edge step in figure 3.19(b). The result of a measurement is followed by possible chemical reactions involved in the perovskite formation process from precursor (MAI: PbCl₂) molar of ratio 3:1 (Pan et al., 2016) shows in table 3.6

Table 3.6 The data from linear combination fitting of CH₃NH₃PbI_(3-x)Cl_x in spectra of Chloride with structure of perovskite for FEFF XANE calculation.

Structure type	Time and temperature to annealing	
	30 min./200°C	60 min./200°C
Pm ₁	38.0	35.1
Pm ₂	61.8	59.6
Cc	17.6	20.1
PbCl ₂ Calculation	52.1	53.2
MACl Calculation	47.9	46.8

The data from table 3.7 represent to the constrain ratio of Cl in structure of PbCl₂ increasing when we increase time to annealing and for MACl decreased when increase time to annealing due to MACl can evaporate in lower temperature than PbCl₂ and in figure 3.19 the shape of peak indicate about possibility of Cl formation in MACl and PbCl₂.

Table 3.7 The data from linear combination fitting of $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ in normalized K edge XANES spectra of Chloride with PbCl_2 and MACl from calculation.

CHAPTER IV

STANDARD CHARACTERIZATION

RESULTS AND DISCUSSIONS

The $\text{CH}_3\text{NH}_3\text{I}$ power precursors from different solvents were used to synthesis hybrid perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$ powders by solid state method with varying conditions. From the result of characterization comparable between $\text{CH}_3\text{NH}_3\text{I}$ power washed by acetone and dry in Ar and $\text{CH}_3\text{NH}_3\text{I}$ dissolved in diethyl ether after that precipitation in N, N-dimethylformamide (DMF) shown that the quality of hybride perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$ powders thus confirm the effective of the new preparation route and found that the synthesis time for MAI synthesis can be shorten by four times from dimethylformamide (DMF) to acetone. From the result of XRD and XAS, After that we synthesized $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ from difference ratio of precursor, vary times and temperature and characterized materials. From the result of XRD and XAS. we found Cl can't be substituted for I in the X side structure of perovskite (ABX_3) by solid state methods.

Abstract

The emerging of perovskite solar cell has attracted many interests in the synthesis and characterization of hybrid perovskite materials related to methylammonium iodide (MAI) due to various promising properties. In this work, we found a faster way to synthesize hybrid perovskite $\text{CH}_3\text{NH}_3\text{PbI}_3$ and $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ ($x = 0, 1, 2$) powders from a different solvent in the preparation process of MAI precursor. In addition, it was found that in $\text{CH}_3\text{NH}_3\text{PbI}_{(3-x)}\text{Cl}_x$ powders, as characterized by XRD and XAS, with a solid-state method employed Cl atoms cannot directly substitute for I in the perovskite (ABX_3) structure.

Abstract

Time-resolved X-ray absorption spectroscopy (TRXAS) beamline (BL2.2) was constructed to utilize a synchrotron radiation produced by a 1.2 T bending magnet from a 1.2 GeV storage ring at the Synchrotron Light Research Institute (SLRI), Thailand. The main optical component of the TRXAS beamline is an energy dispersive monochromator (EDM) which was donated by the University of Bonn, Germany. Using the energy-dispersive scheme with a position-sensitive detector, the beam size at the sample position can be small and have a fast detection speed in the XAS spectrum. At BL2.2, XAS measurement can be performed in the transmission mode using a 1024-pixel position-sensitive detector (PSD) and x-ray scintillator. Currently, the maximum measurable x-ray energy has been extended to 12 keV for the Pt L₃-edge EXAS measurement. Due to the advantages of the energy-dispersive setup, this beamline has focused on *in-situ* XAS experiments. In this review, the researchers summarize the developments of experimental tools to characterize catalysts, Li-ion batteries, and thin film using TRXAS to determine their electronic properties and structure under applied conditions.
