ลำนไพลองอาจารย์ที่ปรึกษาร่วม____________________________
When ultrasonic wave encounter rough surfaces, they become scattered, leading to speckle noise in an ultrasound image. The speckle noise occurring can be explained statistically by the Rayleigh distribution:

\[ R_\sigma(r) = \frac{r}{\sigma^2} e^{-\frac{r^2}{2\sigma^2}}, \]

where \( r \geq 0 \) and \( \sigma \) is a parameter.

One mathematical model for reconstructing an observed noisy ultrasound image is the integral equation

\[
E(u) = \beta \iint_\Omega \left( \sqrt{u_x^2 + u_y^2} \right) dA + \iint_\Omega \left( \frac{\tilde{u}_x^2}{u_x^2} + 2 \ln u + F(\tilde{u}) \right) dA,
\]

where \( F(\tilde{u}) \) being a constant depending on \( \tilde{u} \), for coordinate \((x, y)\), \( u(x, y) \) is intensity of desired image, \( \tilde{u}(x, y) \) is intensity of observed image and \( \Omega \) is the image domain.

The Calculus of Variations is the tool used to finding an optimal solution \( u \) of the integral equation. It transforms the integral equation to the differential equation

\[
\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta u^3} (\tilde{u}^2 - u^2) = 0,
\]
where \( u = \tilde{u} \) on \( \partial \Omega \), which is called Euler-Lagrange equation.

The solution \( u \) is expected to be the noiseless image. The gradient descent method is used to find the solution of the Euler-Lagrange equation numerically in the prototype software. The results show that the noise in the ultrasound images and videos is reduced.
ACKNOWLEDGEMENTS

I would like to express my sincere gratitude to my thesis advisor, Asst. Prof. Dr. Jessada Tanthanuch and thesis co-advisor, Dr. Paramate Horkaew, for their support, patient help, providing me with extensive literature background and offering many useful suggestions. Also, I am indebted Dr. Chumrus Sakulpaisarn for his ultrasound videos.

In addition, I would like to acknowledge the personal and professional support received from the faculty of the School of Mathematics, Suranaree University of Technology: Assoc. Prof. Dr. Prapasri Asawakun, Prof. Dr. Sergey Meleshko, Prof. Dr. Pairote Sattayatham, Assoc. Prof. Dr. Nikolay Moshkin, Asst. Prof. Dr. Arjuna Chaiyasena, and Asst. Prof. Dr. Eckart Schulz.

CHAPTER I

INTRODUCTION

Ultrasound images provide clinicians with non-invasive, low cost and real-time images which can help them in diagnosis, planning and therapy. However, the ultrasonic wave encounters rough surfaces which results in scattering and leads to noise which is called speckle noise.

According to the literature review, there are many researches concerned with speckle filters for radar images. For example the filter by Frost et al., the filter by Lee, the filter by Kuan et al. and the homomorphic filter.

Frost et al. describe a filter dealing with multiplicative noise model while the additive noise model is used in the filter by Kuan et al. Moreover, Lee adapted the linear filter to consider the multiplicative noise model, while the homomorphic filter uses the logarithm function to transform the multiplicative noise model to the linear filter. The method of minimum mean square error is used for these filters. See more details of all of these filter in APPENDIX A.

The main disadvantage of the above filters is that we have to know the information of the noise in the computation. Difficulties arise when we work with an ultrasound video because we do not have the speckle noise information.

This problem can be solved by the mathematical model called the variational approach. The representation of the image in several variational models is presented by

\[ \tilde{u}(x, y) = u(x, y) + n(x, y), \]

where \((x, y)\) is the spatial coordinate, \(u(x, y)\) is intensity of the desired image at
coordinate \((x, y)\), \(\tilde{u}(x, y)\) is the intensity of the observed image and \(n(x, y)\) is the intensity of additive noise at coordinate \((x, y)\). The variational approach is used for finding the desired image \(u\) from the obtained image \(\tilde{u}\).

There are studies of digital image denoising models dealing with the variational approach, for example

1. **The ROF model (1992)**

In 1992, Rudin, Osher, and Fatemi presented a mathematical denoising model which is called the ROF model which uses the additive noise model and is based on calculus of variation. The ROF model considers \(u\) as the solution to a problem of calculus of variation which minimizes the functional

\[
F(u) = \iint_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \lambda \iint_{\Omega} (u - \tilde{u})^2 dA,
\]

where \(\Omega \in \mathbb{R}^2\) is the domain of the image functions and \(\lambda\) is a chosen parameter. By calculus of variations, the solution of this problem is obtained when the Euler-Lagrange differential equation is satisfied, i.e.

\[
\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \lambda (u - \tilde{u}) = 0,
\]

where \(\frac{\partial u}{\partial N} = 0\) on \(\partial \Omega\) and \(N\) is the normal vector to the boundary \(\partial \Omega\).

2. **The variational approach for Poisson noise (2007)**

Le, Chatrand and Asaki adapted the ROF model to reduce Poisson noise in the image by minimizing the functional

\[
G(u) = \beta \iint_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \iint_{\Omega} (u - \tilde{u} \ln u) dA.
\]

The Euler-Lagrange differential equation for solving this problem is

\[
\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{1}{\beta u} (u - \tilde{u}) = 0,
\]

where \(\frac{\partial u}{\partial N} = 0\) on \(\partial \Omega\) and \(N\) is the normal vector to the boundary \(\partial \Omega\).
In this thesis, a variational approach adapted from the ROF model is used to construct the model to reduce the speckle noise in the ultrasound image. The model is to minimize the functional

$$E(u) = \beta \iint_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \iint_{\Omega} \left( \frac{\tilde{u}^2}{u^2} + 2 \ln u + F(\tilde{u}) \right) dA,$$

where \( \beta \) is a chosen parameter and \( F(\tilde{u}) \) is a function of \( \tilde{u} \). We show that this minimization problem has a unique solution.

Here, the Euler-Lagrange equation for minimizing \( E(u) \) is

$$\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta u^3} (\tilde{u}^2 - u^2) = 0,$$

where \( u = \tilde{u} \) on \( \partial \Omega \).

The solution of the above problem is approximated by the numerical method called gradient descent method. Furthermore, prototype software for the model implementation is developed. The pattern image and the Lenna image are used to evaluate the proposed model by comparing the correlation coefficient of the noisy images and the reconstructed images to the original ones. It is found that the model can be used to denoise noisy images and ultrasound videos. The description of the results is shown in section 4.4.
CHAPTER II
RAYLEIGH DISTRIBUTION AND SPECKLE NOISE

This chapter presents the mathematical background of speckle noise which concerns with the Rayleigh distribution.

2.1 Rayleigh distribution

The Rayleigh distribution is a continuous probability distribution. It can arise when a two-dimensional vector has elements that are normally distributed random variables, independent and they both have zero mean and equal variance. The vector’s magnitude will then have a Rayleigh distribution.

Definition 2.1. The Rayleigh probability density function is

\[
R_\sigma(r) = \frac{r}{\sigma^2} e^{-\frac{r^2}{2\sigma^2}},
\]

where \(r \geq 0\) and \(\sigma\) is parameter.

2.2 Derivation of the Rayleigh probability density function

Let \(\langle x, y \rangle \in \mathbb{R}^2\) be a two-dimensional vector where \(x\) and \(y\) are normally distributed random variables, independent and both having zero mean and equal variance. By definition of normal distribution, the probability density of the random variable \(x\) is

\[
N_\sigma(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}},
\]
where $\sigma$ is a variance.

Similarly, the probability density of the random variable $y$ is

$$N_\sigma(y) = \frac{1}{\sigma \sqrt{2\pi}} e^{-\frac{y^2}{2\sigma^2}}.$$  

Since $x$ and $y$ are independent then, the probability density function in the rectangular coordinate of $<x, y>$ is

$$\hat{R}(x, y) = N_\sigma(x) N_\sigma(y) = \frac{1}{2\pi \sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}}.$$  

We have the joint distribution in rectangular coordinates as

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \hat{R}(x, y) dx dy = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{1}{2\pi \sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}} dx dy.$$  

By changing to the polar coordinate we let $x = r \cos \theta$ and $y = r \sin \theta$. The corresponding Jacobian is

$$\left| \begin{array}{cc}
\frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} \\
\frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta}
\end{array} \right| = r.$$  

By the theorem of changing variables to polar form (Wade, 1999) and property of distribution, we have

$$\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{1}{2\pi \sigma^2} e^{-\frac{(x^2+y^2)}{2\sigma^2}} dx dy = \int_{0}^{2\pi} \int_{0}^{\infty} \frac{r}{2\pi \sigma^2} e^{-\frac{r^2}{2\sigma^2}} dr d\theta = 1. \quad (2.2)$$  

The marginal density function of $r$ is obtained by integrating $\hat{R}(r, \theta)$ with respect to $\theta$, thus we get

$$\hat{R}(r) = \int_{0}^{2\pi} \frac{r}{2\pi \sigma^2} e^{-\frac{r^2}{2\sigma^2}} d\theta = \frac{r}{\sigma^2} e^{-\frac{r^2}{2\sigma^2}}.$$  

This function is known as the Rayleigh density function and

$$R_\sigma(r) = \begin{cases} 
0 & \text{if } r < 0 \\
\int_{0}^{r} \frac{\tau}{\sigma^2} e^{-\frac{\tau^2}{2\sigma^2}} d\tau & \text{if } r \geq 0
\end{cases}$$
is a Rayleigh distribution.

The notation $R_\sigma(r) = \frac{r}{\sigma^2} e^{-\frac{r^2}{2\sigma^2}}$ is denoted for the Rayleigh density function in this thesis.

### 2.3 Harmonic Waves

#### 2.3.1 One-Dimensional Waves and Harmonic Waves

First, we will describe the mathematical expression for wave motion and the harmonic wave.

**Definition 2.2.** Let $\psi$ be an $n$-dimensional vector, say $\psi = \psi(x_1, x_2, ..., x_n)$. The Laplacian $\nabla^2 \psi$ of $\psi$ is defined by

$$\nabla^2 \psi = \frac{\partial^2 \psi}{\partial x_1^2} + \frac{\partial^2 \psi}{\partial x_2^2} + ... + \frac{\partial^2 \psi}{\partial x_n^2}.$$

Note that we may sometimes replace $x_n$ with variable $t$.

**Definition 2.3.** The differential wave equation which describes propagation of waves with speed $v$ respect to time $t$ is given by

$$\nabla^2 \psi = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2}.$$

In particular, the one-dimensional differential wave equation is given by

$$\frac{\partial^2 \psi}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 \psi}{\partial t^2}.$$

**Definition 2.4.** A function $y = f(x \pm vt)$ is said to be a function of one-dimensional wave which moves along the $x$-axis at speed $v$ relative to coordinate $(x, y)$ if it satisfies the one-dimensional differential wave equation,

$$\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 y}{\partial t^2}. \quad (2.3)$$
Definition 2.5. **Harmonic wave** is a particular wave which involves the sine function

\[ y = A \sin[c(x \pm vt)] \]

or cosine function

\[ y = A \cos[c(x \pm vt)], \]

where \( A \) and \( c \) are constants. Note that \( A \) is called the amplitude of the wave and can be assumed to be nonnegative.

We claim that \( y = A \sin[c(x \pm vt)] \) satisfies the one-dimensional differential wave equation. Since

\[
\frac{\partial^2 y}{\partial x^2} = -Ac^2 \sin[c(x \pm vt)]
\]

and

\[
\frac{\partial^2 y}{\partial t^2} = -Ac^2v^2 \sin[c(x \pm vt)].
\]

This shows that \( y = A \sin[c(x \pm vt)] \) satisfies the one-dimensional differential wave equation, so it is a one-dimensional wave.

Similarly, in the case of \( y = A \cos[c(x \pm vt)] \), we conclude that it is also a one-dimensional wave.

Denote \( \omega = cv \) which is called the *angular frequency*. With these relationships, it is easy to show the equivalence of the following general forms for harmonic waves: \( y = A \sin[cx \pm \omega t] \). Note that we only consider the case of the sine function because the case of the cosine function is similar.

### 2.3.2 Superposition of harmonic Waves of the Same Frequency

It is necessary to deal with situations in which two or more such waves arrive at the same point in space or exist together along the same direction. Several im-
portant cases of the combined effects of two or more harmonic waves are described in this section. The first case deals with the superposition of harmonic waves of different amplitudes and phases but with the same frequency. This leads to an important difference between the irradiance attainable from randomly phased and coherent harmonic waves.

To explain the combined effects of waves, we require the superposition principle*.

By the superposition principle, the superposition of harmonic waves may be expressed in terms of equation

$$ y = y_1 + y_2, $$

where $y_1$ and $y_2$ are the independent waves which exist together in the space.

The time variations of the harmonic waves at the given point can be expressed by

$$ y_1 = A_1 \sin(\omega t + \alpha_1), $$

$$ y_2 = A_2 \sin(\omega t + \alpha_2), $$

where $A_1$, $A_2$ are amplitudes of $y_1$ and $y_2$, $\alpha_1$, $\alpha_2$ are phases of $y_1$ and $y_2$ respectively.

By the superposition principle, the resultant $y_R$ at the point is

$$ y_R = y_1 + y_2 = A_1 \sin(\omega t + \alpha_1) + A_2 \sin(\omega t + \alpha_2). $$

Using the trigonometric identity for sum of two sine functions with different angles and recombining terms,

$$ y_R = (A_1 \cos \alpha_1 + A_2 \cos \alpha_2) \sin \omega t + (A_1 \sin \alpha_1 + A_2 \sin \alpha_2) \cos \omega t. $$

*The superposition principle says that “the resultant displacement is the sum of the separate displacements of the constituent waves”.

Notice that if we set magnitude and phase angle as vectors and add them, a resultant or sum is found with magnitude $A$ and phase $\alpha$. The components of the resultant are

$$A \cos \alpha = A_1 \cos \alpha_1 + A_2 \cos \alpha_2$$

and

$$A \sin \alpha = A_1 \sin \alpha_1 + A_2 \sin \alpha_2.$$ 

The quantities $A$ and $\alpha$ are defined by this technique, hence

$$y_R = A \cos \alpha \sin \omega t + A \sin \alpha \cos \omega t$$
or

$$y_R = A \sin(\omega t + \alpha).$$

We conclude that the resultant wave $y_R$ is another harmonic wave of the same frequency $\omega t$, with amplitude $A$ and phase $\alpha$. The cosine law may be applied to yield an expression for $A$,

$$A^2 = A_1^2 + A_2^2 + 2A_1A_2 \cos(\alpha_2 - \alpha_1)$$

and the phase angle is given by

$$\alpha = \tan^{-1}\left(\frac{A_1 \sin \alpha_1 + A_2 \sin \alpha_2}{A_1 \cos \alpha_1 + A_2 \cos \alpha_2}\right).$$

Using induction, these computation generalize to the superposition of $N$ harmonic waves:

$$y_k = A_k \sin(\omega t + \alpha_k)$$
of amplitude $A_k$ and phase $\alpha_k$. The resultant will be a wave

$$y_R = A \sin(\omega t + \alpha),$$

where

$$A \cos \alpha = A_1 \cos \alpha_1 + A_2 \cos \alpha_2 + \ldots + A_N \cos \alpha_N.$$  \hspace{1cm} (2.4)
\[ A \sin \alpha = A_1 \sin \alpha_1 + A_2 \sin \alpha_2 + \ldots + A_N \sin \alpha_N. \] (2.5)

Thus,

\[ \alpha = \tan^{-1} \left( \frac{\sum_{k=1}^{N} A_k \sin \alpha_k}{\sum_{k=1}^{N} A_k \cos \alpha_k} \right) \]

and by the Pythagorean theorem,

\[ A^2 = \left( \sum_{k=1}^{N} A_k \sin \alpha_k \right)^2 + \left( \sum_{k=1}^{N} A_k \cos \alpha_k \right)^2. \]

The above equation may profitably be cast into a form that looks more like a generalization of the cosine law. Expanding each term, we have

\[ A^2 = \sum_{k=1}^{N} A_k^2 (\sin^2 \alpha_k + \cos^2 \alpha_k) + 2 \sum_{k=1}^{N} \sum_{j>k} A_k A_j (\cos \alpha_k \cos \alpha_j + \sin \alpha_k \sin \alpha_j). \]

Note that the double sum represents all cross products, by the use of notation \( j > k \) the self-product already accounted for in the first term and also avoiding a duplication of the indices.

Using the trigonometric identity of \( \cos(\alpha_i - \alpha_j) \) in the second term, finally

\[ A^2 = \sum_{k=1}^{N} A_k^2 + 2 \sum_{k=1}^{N} \sum_{j>k} A_k A_j \cos(\alpha_k - \alpha_j). \] (2.6)

The pair of equations (2.4) and (2.5) are easily express in exponential form. Each pair \((A_k, \alpha_k)\) uniquely determines a complex number

\[ A_k e^{i \alpha_k} = A_k (\cos \alpha_k + i \sin \alpha_k). \]

Then the resultant wave is expressed by

\[ A e^{i \alpha} = A (\cos \alpha + i \sin \alpha). \]

Observe that by (2.4) and (2.5),

\[ A e^{i \alpha} = A \cos \alpha + i A \sin \alpha \]

\[ = A \cos \alpha + i A \sin \alpha \]

\[ = \sum_{k=1}^{N} A_k \sin \alpha_k + i \sum_{k=1}^{N} A_k \sin \alpha_k \]

\[ = \sum_{k=1}^{N} A_k e^{i \alpha_k}. \]
Summarizing, the sum of $N$ harmonic waves of identical frequency is again a harmonic wave of the same frequency, with amplitude given by $A$ and phase given by $\alpha$.

### 2.3.3 Coherence and Incoherence

Before discussing speckle in the next section, *coherence* and *incoherence* are introduced. The term coherence and incoherence are used to describe the correlation between phases of *monochromatic waves*.

**Definition 2.6.** Let

\[
\begin{align*}
y_1(x) &= A_1 \sin(\omega x + \alpha_1), \\
y_2(x) &= A_2 \sin(\omega x + \alpha_2)
\end{align*}
\]

be harmonic waves with the same frequency $\omega$. The *relative phase* of $y_1$ and $y_2$ is given by $\alpha_1 - \alpha_2$.

**Definition 2.7.** Waves are said to be **coherent** if they have a *constant relative phase*, which also implies that they have the same frequency. In the superposition of coherent waves, individual amplitudes add together. As present in figure 2.1(a) and 2.1(b), waves add constructively or subtract destructively, depending on their relative phase.

**Definition 2.8.** Waves are said to be **incoherent** if they have *random relative phase*, i.e. they are combined with a lot of different phases as shown in figure 2.2

---

†A *monochromatic wave* is represented by a wave function with harmonic time dependence. Amplitude and phase are generally position dependent, however the wave function is a harmonic function of time with the same frequency at all positions.
(a) Figure of wave that combine in phase add up relatively high irradiance (constructive coherent).

(b) Figure of wave that combine $\pi$ radian out of phase cancel out and yield zero irradiance (destructive coherent).

**Figure 2.1** The figures of coherent waves

---

**Figure 2.2** The figure of waves that combine with lots of different phases nearly cancel out and yield very low irradiance (incoherent).

### 2.4 Speckle

**Definition 2.9. Speckle** is a random pattern which has a negative impact on *coherent imaging*, including ultrasound imaging. It is a result of the superposition of many waves, which have different phases (incoherent).

Speckle occurs in an ultrasound image because the ultrasonic wave encounters rough surfaces that result in the scattering of waves, and we can see in figure 2.3, each scattered wave from a rough surface has a different phase which leads to the forming of speckles.
Next, we will use the Rayleigh distribution to describe the speckles from the statistical point of view.

A sum of a very large number $N$ of waves which have random phases is considered. Assume that the $k$-th wave has random amplitude $A_k/\sqrt{N}$ and random phase $\alpha_k$. The resultant wave $a$ with amplitude $|a|$ and phase $\alpha$ is given by

$$a = |a|e^{i\alpha} = \frac{1}{\sqrt{N}} \sum_{k=1}^{N} A_k e^{i\alpha_k},$$

where $i = \sqrt{-1}$.

Let $a_R$ and $a_I$ denote the real and imaginary parts of the resultant, respectively,

$$a_R = \frac{1}{\sqrt{N}} \sum_{k=1}^{N} A_k \cos \alpha_k,$$
$$a_I = \frac{1}{\sqrt{N}} \sum_{k=1}^{N} A_k \sin \alpha_k,$$

where

$$|a| = \sqrt{a_R^2 + a_I^2}.$$

Goodman (2000) showed that $a_R$ and $a_I$ are normally distributed, have zero mean, have the same variance and are independent.

If we consider $|a|$ as a random variable, thus the Rayleigh distribution can be used to describe the speckle statistically and $|a|$ is called a Rayleigh random variable.
Note that the amplitude of the harmonic wave, $|a|$, corresponds to the intensity of the image at each point.
CHAPTER III
CALCULUS OF VARIATIONS AND ROF MODEL

This chapter discusses the calculus of variations which is a mathematical field used for optimization such as the construction of image denoising models. The ROF model, a well-known image denoising model dealing with calculus of variation, is also presented.

3.1 Calculus of Variations

calculus of variations is a field of mathematics that deals with functionals, as opposed to ordinary calculus which deals with functions. Such functionals can be formed as integrals involving an unknown function and its derivatives. The interest is in extremal functions making the functional attain an extremum value. The candidates in the competition for an extremum are functions.

Example 3.1. The problem involves finding the extrema of integrals of the form

\[ I = \int_{\Omega} F(x, y, u, u_x, u_y) dx dy \quad (3.1) \]

over a bounded region \( \Omega \), where \( F \) is uniformly continuous on \( \Omega \).

Assume that \( u \) is the solution, which is continuous, has continuous derivatives up to second order and exists on the boundary of \( \Omega \). We will vary \( u \) by an arbitrary function \( \eta(x, y) \) with \( \eta = 0 \) on the boundary curve of \( \Omega \) and define the function \( u_\epsilon \) by the equation

\[ u_\epsilon(x, y) = u(x, y) + \epsilon \eta(x, y), \]
where \( \epsilon \) is a parameter.

Because of arbitrariness of \( \eta \), \( u_\epsilon \) represents any function with continuous second derivatives on \( \Omega \). Out of all these \( u_\epsilon \), we want to pick the one function that makes \( I \) smallest or largest. Now \( I \) is a function of the parameter \( \epsilon \). When \( \epsilon = 0 \), we have

\[
  u_\epsilon(x, y) = u(x, y),
\]

which is the desired solution. Our problem is to make \( I \) taking its extremum value, when \( \epsilon = 0 \). In other words, we want

\[
  \left. \frac{dI}{d\epsilon} (u + \epsilon \eta) \right|_{\epsilon=0} = 0.
\]

Differentiating equation (3.1) with respect to \( \epsilon \), we get

\[
  \frac{dI}{d\epsilon} (u + \epsilon \eta) \bigg|_{\epsilon=0} = \iint_\Omega \left( F_u \eta + F_{u_x} \eta_x + F_{u_y} \eta_y \right) dxdy
\]

\[
= \iint_\Omega (F_u \eta) dxdy + \iint_\Omega (F_{u_x} \eta_x) dxdy + \iint_\Omega (F_{u_y} \eta_y) dxdy = 0,
\]

which will be transformed by integrating by parts.

Consider \( \iint_\Omega (F_{u_x} \eta_x) dxdy \), we will compute \( \int (F_{u_x} \eta_x) dx \) by integrating by parts. Let \( w = F_{u_x} \), we have \( dw = \left( \frac{\partial}{\partial x} F_{u_x} \right) dx \), \( dv = (\eta_x) dx \) and \( v = \eta \), then

\[
\int (F_{u_x} \eta_x) dx = wv - \int vdw
\]

\[
= F_{u_x} \eta - \int \left( \eta \frac{\partial}{\partial x} F_{u_x} \right) dx.
\]

By Gauss’s integral theorem (Courant, 1924), we obtain

\[
\iint_\Omega (F_{u_x} \eta_x) dxdy = \int_\partial \Omega (F_{u_x} \eta) dy - \iint_\Omega \left( \eta \frac{\partial}{\partial x} F_{u_x} \right) dxdy,
\]

where \( \partial \Omega \) is the boundary curve of \( \Omega \).

Similarly,

\[
\iint_\Omega (F_{u_y} \eta_y) dxdy = \int_\partial \Omega (F_{u_y} \eta) dx - \iint_\Omega \left( \eta \frac{\partial}{\partial y} F_{u_y} \right) dxdy.
\]
Thus, we obtain
\[
\left. \frac{d\mathcal{I}}{dc}(u + \epsilon\eta) \right|_{c=0} = \int_{\Omega} \eta \left( F_u - \frac{\partial}{\partial x} F_{u_x} - \frac{\partial}{\partial y} F_{u_y} \right) \, dx \, dy \\
+ \int_{\Gamma} \eta (F_{u_x}) \, dy + \int_{\Gamma} \eta (F_{u_y}) \, dx = 0.
\]

Since \( \eta = 0 \) on the boundary \( \Gamma \) of \( \Omega \), the second term and the third term on the right side vanish. Hence
\[
\int_{\Omega} \eta \left( F_u - \frac{\partial}{\partial x} F_{u_x} - \frac{\partial}{\partial y} F_{u_y} \right) \, dx \, dy = 0.
\]

By continuity and arbitrariness of \( \eta \) on \( \Omega \), then
\[
F_u - \frac{\partial}{\partial x} F_{u_x} - \frac{\partial}{\partial y} F_{u_y} = 0.
\]

This is equivalent to the equation
\[
\frac{\partial}{\partial x} F_{u_x} + \frac{\partial}{\partial y} F_{u_y} - F_u = 0, \tag{3.2}
\]
which is called Euler-Lagrange differential equation.

There are a lot of works establishing the existence of extrema and characterizing them. In many cases, extremal functions or curves can be expressed as solutions to differential equations. In particular, we will use the Euler-Lagrange differential equation presented in equation (3.2).

### 3.2 The ROF Model

In image processing, it is important to decrease the noise in the image. If we represent the noisy image as a function \( \tilde{u} \) obtained by adding noise \( n \) to a noiseless image \( u \), then \( \tilde{u} \) can be represented by
\[
\tilde{u}(x, y) = u(x, y) + n(x, y), \tag{3.3}
\]
where \( u(x, y) \) is intensity of desired image at coordinate \((x, y)\), \( \tilde{u} \) is intensity of observed image at coordinate \((x, y)\) and \( n(x, y) \) is intensity of additive noise at coordinate \((x, y)\).

Our purpose is to find the desired image \( u \) which is the solution of the corresponding denoising problem.

Rudin, Osher and Fatemi (1992) presented a mathematical denoising model called the ROF model which is based on gradient, the least squares problem and calculus of variation. In particular, calculus of variation leads the ROF model to the Euler-Lagrange differential equation similar to example 3.1.

Before discussing the ROF model, we need to review about the gradient and the least square problem.

### 3.2.1 Gradient

Given a function \( f(x, y) \), the partial derivatives \( f_x \) and \( f_y \) represent the rates of change of \( f \) in directions parallel to the \( x \)-axes and the \( y \)-axes respectively. However, it is also necessary to consider rates of change of \( f(x, y) \) in other directions. This is the reason why we study the gradient.

**Definition 3.1.** Let \( f \) be a function of \( x \) and \( y \). The **gradient** of \( f \) is denoted by \( \nabla f \) and is defined by

\[
\nabla f = < f_x, f_y >
\]

and its magnitude is defined by

\[
\| \nabla f \| = \sqrt{f_x^2 + f_y^2}.
\]

In vector calculus, the gradient is a vector which points in the direction of the greatest rate of increase and whose magnitude is the greatest rate of change. We use the gradient to investigate the directional derivative.
Definition 3.2. Let \( f \) be a function of \( x \) and \( y \). If \( v = <v_1, v_2> \) is a unit vector, then the directional derivative of \( f \) in the direction of \( v \) at \((x, y)\) is denoted by \( D_v f(x, y) \) and is defined by

\[
D_v f(x, y) = \nabla f(x, y) \cdot v.
\]

If \( \theta \) is the angle between \( \nabla f \) and \( v \), then

\[
D_v f = \nabla f \cdot v = \|\nabla f\| \|v\| \cos \theta = \|\nabla f\| \cos \theta.
\]

This equation tells us that the maximum value of \( D_v f(x, y) \) is \( \|\nabla f\| \) and this maximum occurs when \( \theta = 0 \), that is when \( v \) is in the direction of \( \nabla f \). Geometrically, this mean that the surface \( z = f(x, y) \) has its maximum slope at point \((x, y)\) in the direction of the gradient, where the maximum slope is \( \|\nabla f\| \).

3.2.2 The Least Square Problem

A task that occurs in scientific investigation is finding a straight line that fits some set of data points. Typically we have a large number of points \((x_i, y_i)\), where \( i = 1, 2, \ldots, n \), and we have theoretical reason to believe that these points should lie on a straight line. Thus we seek a linear function \( p(x) = a + bx \) such that \( p(x_i) = y_i \), where \( i = 1, 2, \ldots, n \). In fact, the points will deviate from a straight line, thus it is not possible to find a linear function \( p(x) \) that passes through all of them which is the best representation of all data \((x_i, y_i)\). Instead, one settles for a line that fits the points well, in the sense that the errors

\[
|y_i - p(x_i)|,
\]

where \( i = 1, 2, \ldots, n \) are made as small as possible.
Denote $r = \langle y_1 - p(x_1), \ldots, y_n - p(x_n) \rangle$ as the vector of residuals. We can solve our problem by choosing a vector norm $\| \cdot \|$. The solution depends on the choice of norm. If we choose the Euclidean norm \(^*\), we minimizing the quantity

$$\|r\|_2 = \left( \sum_{i=1}^{n} |y_i - p(x_i)|^2 \right)^{\frac{1}{2}}.$$

To minimize $\|r\|_2$ is equivalent to minimize

$$\left( \|r\|_2 \right)^2 = \sum_{i=1}^{n} |y_i - p(x_i)|^2.$$

Thus we are minimizing the sum of the squares of the residuals. For this reason the problem of minimizing $\|r\|_2$ is called the least square problem.

In the continuous case, the discrete points are replaced by continuous data $\{(x, y(x)) | x \in [a, b]\}$. Thus given a function $y$ defined on some bounded interval $[a, b]$, we seek a linear function $\psi$ such that $\psi$ approximates $y$. As norm $\| \cdot \|$ of a continuous function $h$ on $[a, b]$ we choose

$$\|h\|_2 = \left( \int_{a}^{b} |h(x)|^2 dx \right)^{\frac{1}{2}},$$

which is called the $L^2$-norm. Then the summation in the discrete case is substituted by the integral, and the least square problem in the continuous case is to find a continuous function $\psi(x)$ minimizing

$$\int_{a}^{b} |y(x) - \psi(x)|^2 dx.$$

### 3.2.3 Description of the ROF Model

From the relation between a noisy image $\tilde{u}$ and a noiseless image $u$ in equation (3.3), we wish to reconstruct $u$ from $\tilde{u}$. The most conventional method

---

*See the definition of vector norm in Introductory Functional Analysis with Application (Kreyszig, 1988).

\(^*\)Let $x = \langle x_1, \ldots, x_n \rangle \in \mathbb{R}^n$, Euclidian norm on $\mathbb{R}^n$ is the vector norm defined by $\|x\| = \left( \sum_{i=1}^{n} |x_i|^2 \right)^{\frac{1}{2}}$. \(^*\)
involves the least squares with the $L^2$ - norm because this leads to a linear term in the Euler-Lagrange equation.

Rudin et al. (1992) presented the denoising model which applies the solution of the one-dimensional linear integral equation of the first kind. In the two-dimensional case, the problem is to minimize

$$
\iint_{\Omega} (u_{xx} + u_{yy})^2 dxdy + \iint_{\Omega} (u - \tilde{u})^2 dxdy.
$$

The first term is a generalization of the one-dimensional case and the second term is the error term. However the result is disappointing in digital image denoising.

After that, they found that when the $L^1$-norm is applied to the gradient, which is defined by

$$
\iint_{\Omega} \|\nabla u\| dxdy = \iint_{\Omega} \left(\sqrt{u_x^2 + u_y^2}\right) dxdy,
$$

then this $L^1$ approximation looks better than the $L^2$ approximation on a computer screen. This is the reason why Rudin et al. use the $L^1$-norm of the gradient in the ROF model.

**Definition 3.3.** Let $\tilde{u}$ be a function describing the noisy image and $u$ a function describing the noiseless image with respect to $\tilde{u}$. The ROF model considers $u$ as a solution to a problem of calculus of variations, which minimizes the functional

$$
F(u) = \iint_{\Omega} \left(\sqrt{u_x^2 + u_y^2}\right) dxdy + \lambda \iint_{\Omega} (u - \tilde{u})^2 dxdy, \quad (3.4)
$$

where $\Omega \in \mathbb{R}^2$ is the domain of the image functions and $\lambda$ is a chosen parameter.

---

\textsuperscript{†}Let $K(x,y)$ and $g(x)$ be the given bounded functions, the linear integral equations of the first kind is written as $\int_{a}^{b} K(x,y)f(y) dy = g(x)$.

Phillips (1962) showed that finding the solution of this equation is equivalent to minimizing $\int_{a}^{b} (f''(y))^2 dy$. 

---
The first term of equation (3.4) is a regularization term which is the magnitude of $\nabla u$, i.e. it is the maximum rate of change of $u$. By regularization we mean that the gradients of $u$ over $\Omega$ should be small on the average. The second term is the data-fidelity term. In fact, if we minimize this term we can see in equation (3.3) that we find the least square of the noise over the region $\Omega$.

By calculus of variations, the solution of equation (3.4) obtained by the Euler-Lagrange differential equation is satisfied, i.e.

$$\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \lambda (u - \tilde{u}) = 0,$$

where $\frac{\partial u}{\partial N} = 0$ on $\Omega$, here $N$ is the normal vector to the boundary $\Omega$. 
CHAPTER IV
RESULT AND CONCLUSION

The model for speckle denoising in the ultrasound image is presented in this chapter. Rayleigh distribution are used for the description of the speckle noise occurring in this model. The method of calculus of variation leads the model to the Euler-Lagrange equation. The equation is solved numerically by the gradient descent method. Finally, the experimental results to verify the model and theorems are also presented.

4.1 Description of the Proposed Model

Assume that \( \tilde{u} \) is a given noisy ultrasound image defined on \( \Omega \), a bounded open rectangle in \( \mathbb{R}^2 \) with piecewise Lipschitz boundary \( \partial \Omega \). We assume that \( \tilde{u} \) is bounded and positive on \( \Omega \) and \( \tilde{u}_{x,y} \) is the intensity of \( \tilde{u} \) at the location \( (x, y) \). Note that \( \tilde{u} \) is assumed to be noiseless on \( \partial \Omega \).

Recall that the image intensity of an ultrasound image is a Rayleigh random variable, which has a density function:

\[
R_\sigma(r) = \frac{r}{\sigma^2} e^{-\frac{r^2}{2\sigma^2}},
\]

where \( r \geq 0 \) is the image intensity and \( \sigma \) is a parameter.

Let \( U_{x,y} \) be a random variable on the set of noiseless images, which corresponds to noiseless image intensity at point \( (x, y) \) and \( \tilde{U}_{x,y} \) be a random variable on the set of observed images, which corresponds to the observed image intensity.

\*See the definition of Lipschitz boundary in definition 4.5.
at point \((x, y)\). We wish to determine the image \(u\) which is most likely given the observed image \(\tilde{u}\).

From the statistical point of view, we are going to find an image \(u\) which maximizes the conditional probability that the intensity of a noiseless image is the most likely given the intensity of the observed image for all \((x, y)\). We assume that \(\Omega\) is pixelleted by \(\Omega = \{(x, y) | x, y = 0, \ldots, N - 1\}\) and the values of image intensity for each pixel \((x, y)\) are independent, thus the conditional probability mentioned is

\[
\prod_{(x,y) \in \Omega} P \left( U_{x,y} = u_{x,y} | \tilde{U}_{x,y} = \tilde{u}_{x,y} \right),
\]

where \(u_{x,y} = u(x, y)\) and \(\tilde{u}_{x,y} = \tilde{u}\). Bayes’ Rule says that

\[
P \left( U_{x,y} = u_{x,y} | \tilde{U}_{x,y} = \tilde{u}_{x,y} \right) = \frac{P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y} \right) P \left( U_{x,y} = u_{x,y} \right)}{P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} \right)},
\]

where, at point \((x, y)\), \(P \left( U_{x,y} = u_{x,y} | \tilde{U}_{x,y} = \tilde{u}_{x,y} \right)\) is the conditional probability of the intensity of the noiseless image \(u\) on the condition of the intensity of the observed image \(\tilde{u}\), \(P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y} \right)\) is the conditional probability of the intensity of the observed image \(\tilde{u}\) on the condition of the intensity of the noiseless image \(u\), \(P(U_{x,y} = u_{x,y})\) is the probability of intensity of the noiseless image and \(P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} \right)\) is the probability of intensity of the observed image \(\tilde{u}\).

In order to maximizing \(P(U_{x,y} = u_{x,y} | \tilde{U}_{x,y} = \tilde{u}_{x,y})\), we are going to find the noiseless image \(u\) which maximizes

\[
\prod_{(x,y) \in \Omega} P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y} \right) P \left( U_{x,y} = u_{x,y} \right).
\]

For each \((x, y)\), \(\tilde{u}\) is Rayleigh random variable and its probability density is

\[
P \left( \tilde{U}_{x,y} = \tilde{u}_{x,y} \right) = \frac{\tilde{u}_{x,y}}{\sigma^2} e^{-\frac{|\tilde{u}_{x,y}|^2}{2\sigma^2}}.
\]
Recall that the above density function $R_{\sigma}(\tilde{u}_{x,y})$ depends on the parameter $\sigma$. Assume the parameter $\sigma$ of the conditional probability of $\tilde{u}$ on the condition of the noiseless image $u$ is a function of $u$, $\sigma = \sigma(u)$. The conditional probability of the intensity of the observed image $\tilde{u}$ at the point $(x, y)$ is

$$P\left(\tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y}\right) = R_{\sigma(u_{x,y})}(\tilde{u}_{x,y}) = \frac{\tilde{u}_{x,y}}{[\sigma(u_{x,y})]^2} e^{-\frac{[u_{x,y}]^2}{2[\sigma(u_{x,y})]^2}}.$$

Expression (4.1) becomes

$$\prod_{(x,y) \in \Omega} \left(\frac{\tilde{u}_{x,y}}{[\sigma(u_{x,y})]^2} e^{-\frac{[u_{x,y}]^2}{2[\sigma(u_{x,y})]^2}}\right) P(U_{x,y} = u_{x,y}). \tag{4.2}$$

Since the natural logarithm function which is denoted by $\ln(x)$ is an increasing continuous function, the function $-\ln(x)$ is a decreasing continuous function. Hence the minimizing of $-\ln \left( \prod_{(x,y) \in \Omega} P\left(\tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y}\right) P(U_{x,y} = u_{x,y}) \right)$ is equivalent to the maximizing expression (4.1). Therefore, we seek a minimizer of

$$-\ln \left( \prod_{(x,y) \in \Omega} P\left(\tilde{U}_{x,y} = \tilde{u}_{x,y} | U_{x,y} = u_{x,y}\right) \right) - \ln \left( \prod_{(x,y) \in \Omega} P(U_{x,y} = u_{x,y}) \right). \tag{4.3}$$

The expression (4.3) becomes

$$\sum_{x=0}^{N-1} \sum_{y=0}^{N-1} \left( \frac{[\tilde{u}_{x,y}]^2}{2[\sigma(u_{x,y})]^2} + 2 \ln \sigma(u_{x,y}) - \ln \tilde{u}_{x,y} \right) - \ln \left( \prod_{(x,y) \in \Omega} P(U_{x,y} = u_{x,y}) \right).$$

We regard this as a discrete approximation of the functional

$$E(u) = -\ln P(u) + \iint_{\Omega} \left( \frac{\tilde{u}^2}{2[\sigma(u)]^2} + 2 \ln \sigma(u) - \ln \tilde{u} \right) dA, \tag{4.4}$$

where $P(u)$ is the probability that the random variable $U_{x,y}$ is equal to the intensity of the noiseless image $u$ at pixel $(x, y)$ for all $(x, y) \in \Omega$. For the model of a variational approach, Green (2002) presents that $P(u)$ is given by

$$P(u) = e^{-\beta \iint_{\Omega} (\sqrt{u_x^2 + u_y^2}) dA},$$
where $\beta$ is a parameter. Hence, functional $E(u)$ becomes

$$E(u) = \beta \int_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \int_{\Omega} \left( \frac{\tilde{u}^2}{2[\sigma(u)]^2} + 2 \ln \sigma(u) - \ln \tilde{u} \right) dA. \tag{4.5}$$

The Euler-Lagrange equation for minimizing $E(u)$ is

$$\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\sigma'(u)}{\beta[\sigma(u)]^3} \left( \tilde{u}^2 - 2[\sigma(u)]^2 \right) = 0. \tag{4.6}$$

Since the last term of equation (4.6) is a data-fidelity term (Le, 2005), the constraint vanishing of it where $u = \tilde{u}$ is considered:

$$\frac{\sigma'(u)}{\beta[\sigma(u)]^3} \left( \tilde{u}^2 - 2[\sigma(u)]^2 \right) = 0. \tag{4.7}$$

For the sake of the simplicity, function

$$\sigma(u) = \frac{u}{\sqrt{2}},$$

is chosen for satisfying the requirement (4.7). The functional $E(u)$ obtained is

$$E(u) = \beta \int_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \int_{\Omega} \left( \frac{\tilde{u}^2}{u^2} + 2 \ln u - \ln \sqrt{2} - \ln \tilde{u} \right) dA. \tag{4.8}$$

The functional $E$ is defined on the set of functions $u$ which are of bounded variation $\dagger$ on $\Omega$ such that $\frac{1}{u^2}$ and $\ln u$ belong to $L^1(\Omega)$, i.e.

$$\int_{\Omega} \left| \frac{1}{u^2} \right| dA \quad \text{and} \quad \int_{\Omega} |\ln u| dA \quad \text{exist.} \quad \text{(4.8)}$$

Hence, the requirements which we impose on $u$ are

$$u \in C(\Omega), u \in C^2(\Omega) \quad \text{and} \quad u \text{ is positive on } \Omega. \tag{4.9}$$

For the uniqueness of the solution $u$, we require that

$$0 < u < \sqrt{3}\tilde{u}, \tag{4.10}$$

which is explained in section 4.2.

The Euler-Lagrange equation for minimizing $E(u)$ is

$$\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta u^3} (\tilde{u}^2 - u^2) = 0, \tag{4.11}$$

where $u = \tilde{u}$ on $\partial\Omega$.

$\dagger$See the definition of bounded variation in Definition 4.4
4.2 Existence and Uniqueness

Next, we will show existence and uniqueness of the minimizer for model (4.8).

In order to show the existence of the minimizer of our model, the compactness-like of \( L^1 \) in the space of function of bounded variation has to be claimed. Sobolev space and space of bounded variation are presented to satisfy the claim.

**Definition 4.1.** Let \( \Omega \) be a subset of \( \mathbb{R}^n \). A function \( f \) belongs to **Sobolev space** \( W^{1,p}(\Omega) \) if \( f \in L^p(\Omega) \), i.e. \( \|f\|_{L^p} \) is finite and all weak partial derivatives \( \frac{\partial f}{\partial x_i} \) exist and belong to \( L^p(\Omega) \), \( i = 1, 2, ..., n \).

Here the norm of \( L^p(\Omega) \) is defined by

\[
\|f\|_{L^p} = \left( \int_{\Omega} |f|^p \right)^{\frac{1}{p}}
\]

and the norm of \( W^{1,p}(\Omega) \) is defined by

\[
\|f\|_{W^{1,p}(\Omega)} = \left( \int_{\Omega} \|f\|^p + |\nabla f|^p \right)^{\frac{1}{p}}.
\]

**Definition 4.2.** Let \( f : \mathbb{R}^n \to \mathbb{R} \).

i) The **support** of \( f \) is the closure of the set of points where \( f \) is nonzero, i.e.

\[
\text{spt} f = \overline{\{x \in \mathbb{R}^n, f(x) \neq 0\}},
\]

where \( \overline{\{\ldots\}} \) is the closure of the set.

ii) The function \( f \) is said to have **compact support** if \( \text{spt} f \) is a compact set.

**Definition 4.3.** \( C^k(\Omega) \) is the set of functions \( f \) defined on \( \Omega \) whose \( k \)-order derivatives exist and are continuous.
The set of functions \( f \) which belong to \( C^k(\Omega) \) for all \( k \in \mathbb{N} \) is denoted by \( C^\infty(\Omega) \).

Also, set
\[
C^1_c(\Omega) = \{ f \in C(\Omega) : f \text{ has compact support} \}.
\]

**Definition 4.4.** Let \( \Omega \) be an open bounded subset of \( \mathbb{R}^n \). A function \( f \in L^1(\Omega) \) is said to be of **bounded variation** in \( \Omega \), if
\[
\| Df \|(\Omega) = \sup \{ \int_\Omega f \text{div} \varphi \mid \varphi \in C^1_c(\Omega, \mathbb{R}^n), \| \varphi(x) \| \leq 1, \forall x \in \Omega \} < \infty.
\]
Here \( C^1_c(\Omega, \mathbb{R}^n) \) denotes the set of \( \varphi : \Omega \rightarrow \mathbb{R}^n \) which is continuously differentiable vector function and its compact support is contained in \( \Omega \). We set
\[
BV(\Omega) = \{ f \in L^1(\Omega) : \| Df \|(\Omega) < \infty \}.
\]
The norm on \( BV(\Omega) \) is defined by
\[
\| f \|_{BV(\Omega)} \equiv \| Df \|(\Omega) + \| f \|_{L^1(\Omega)}.
\]
\( BV(\Omega) \) becomes a Banach space. \( \| Df \|(\Omega) \) is called the **total variation of \( f \)** on \( \Omega \).

**Remark** If \( f \in C^1(\Omega) \) and \( f \) and its first-order partial derivatives lie in \( L^1(\Omega) \), then
\[
\| Df \|(\Omega) = \int_\Omega \| \nabla f \|.
\]

**Theorem 4.1.** Let \( \{ f_k \} \subset BV(\Omega) \) and suppose that \( f_k \rightarrow f \) in the norm of \( L^1(\Omega) \). Then
\[
1. f \in BV(\Omega).
\]
\[
2. \| Df \|(\Omega) \leq \liminf_{k \rightarrow \infty} \| Df_k \|(\Omega).
\]
Definition 4.5. Let $\Omega$ be an open bounded subset of $\mathbb{R}^n$. We say that $\Omega$ is a bounded open set with Lipschitz boundary if for every $a \in \partial \Omega$ there exist a neighborhood $U \in \mathbb{R}^n$ of $a$ and a bijective map $H : \overline{Q} \to \overline{U}$, where

$$Q = \{a = (a_1, \ldots, a_n) \in \mathbb{R}^n, |a_j| < 1, j = 1, 2, \ldots, n\},$$

$$H \in C(\overline{Q}),$$

$$H^{-1} \in C(\overline{U}),$$

$$H(Q_+) = U \cap \Omega,$$

$$H(Q_0) = U \cap \partial \Omega$$

$$H \in C^{0,1}(\overline{Q}),$$

where $Q_+ = \{a \in Q, a_n > 0\}$, $Q_0 = \{a \in Q, a_n = 0\}$ and $C^{0,1}(\overline{Q})$ is the set of $f \in C(\overline{Q})$ so that

$$\sup_{x \neq y \in K} \left\{ \frac{|f(x) - f(y)|}{\|x - y\|} \right\} < \infty,$$

for every compact set $K \subset \overline{Q}$.

Theorem 4.2. Let $\Omega$ be an open bounded subset of $\mathbb{R}^n$ with Lipschitz boundary. Assume $\{f_k\}$ is a sequence in $BV(\Omega)$ satisfying

$$\|f_k\|_{BV(\Omega)} \leq M, \forall k.$$

Then, there exist a subsequence $\{f_{k_j}\}$ and a function $f \in BV(\Omega)$ such that

$$f_{k_j} \to f$$

in the norm of $L^1(\Omega)$.

Remark This theorem says that subsets of $BV(\Omega)$ which are bounded under $\| \cdot \|_{BV(\Omega)}$ are even compact under the norm of $L^1(\Omega)$. See proof of the theorem in Evans (1992).
Additionally, for the uniqueness of the minimizer of the denoising model, convexity is considered.

**Definition 4.6.** A subset $M$ of a vector space $X$ is said to be convex if $y, z \in M$ implies that the line segment

$$L = \{v = \alpha y + (1 - \alpha)z | 0 \leq \alpha \leq 1\}$$

is a subset of $M$.

**Definition 4.7.** A functional $F$ is said to be convex if its domain $\mathbb{D}(F)$ is a convex set and for every $a, b \in \mathbb{D}(F)$,

$$F(\lambda a + (1 - \lambda)b) \leq \lambda F(a) + (1 - \lambda)F(b),$$

where $0 \leq \lambda \leq 1$. In additional if for every $a, b \in \mathbb{D}(F)$, $a \neq b$,

$$F(\lambda a + (1 - \lambda)b) < \lambda F(a) + (1 - \lambda)F(b),$$

where $0 < \lambda < 1$, then $F$ is said to be a strictly convex.

**Theorem 4.3.** If $F$ in equation (3.1) is strictly convex and the minimizer of the equation (3.1) exists, then the minimizer of (3.1) is unique.

**Proof.** Assume that $u$ and $v$ are two minimizers of equation (3.1) such that $u \neq v$, $m$ denoting the value of the minimizer. Define

$$w = \frac{1}{2} u + \frac{1}{2} v.$$ 

So $w_x = \frac{1}{2} u_x + \frac{1}{2} v_x$ and $w_y = \frac{1}{2} u_y + \frac{1}{2} v_y$.

By strict convexity of $F$ we obtain

$$\frac{1}{2} F(x, y, u, u_x, u_y) + \frac{1}{2} F(x, y, v, v_x, v_y) > F\left(x, y, \frac{1}{2} u + \frac{1}{2} v, \frac{1}{2} u_x + \frac{1}{2} v_x, \frac{1}{2} u_y + \frac{1}{2} v_y\right)$$

$$= F(x, y, w, w_x, w_y)$$
and then
\[ m = \frac{1}{2}I(u) + \frac{1}{2}I(v) > I(w) \geq m. \]

This is a contradiction. Hence, our assumption is false. Because of the arbitrariness of \( u \) and \( v \), we conclude that if the minimizer of the equation (3.1) exists, it is unique.

Lemma 4.4. If \( F : (a, b) \to \mathbb{R} \) is continuously twice differentiable and \( F''(u) > 0 \), for every \( u \in (a, b) \) then, \( F \) is strictly convex.

Proof. The Taylor series expansion of \( F \) about the point \( u_0 \in (a, b) \) is
\[ F(u) = F(u_0) + F'(u_0)(u - u_0) + \frac{1}{2}F''(\bar{u})(u - u_0)^2, \]
where \( \min(u_0, u) < \bar{u} < \max(u_0, u) \).

If \( F''(u) > 0 \), for every \( u \neq u_0 \) then the last term is positive.

Let \( u_0 = \lambda u_1 + (1 - \lambda)u_2 \) where \( 0 < \lambda < 1 \). Then
\[ F(u) > F(u_0) + F'(u_0)(u - (\lambda u_1 + (1 - \lambda)u_2)). \]

For the case \( u = u_1 \),
\[ F(u_1) > F(u_0) + F'(u_0)(1 - \lambda)(u_1 - u_2). \]

This implies that
\[ \lambda F(u_1) > \lambda F(u_0) + \lambda(1 - \lambda)F'(u_0)(u_1 - u_2). \]

In the case \( u = u_2 \),
\[ F(u_2) > F(u_0) + F'(u_0)(\lambda)(u_2 - u_1). \]

This implies that
\[ (1 - \lambda)F(u_2) > (1 - \lambda)F(u_0) - \lambda(1 - \lambda)F'(u_0)(u_1 - u_2). \]
Combine the inequalities, we obtain
\[ \lambda F(u_1) + (1 - \lambda)F(u_2) > F(u_0) = F(\lambda u_1 + (1 - \lambda)u_2) \]
and get the strictly convexity result for arbitrary \( u_1, u_2 \) such that \( u_1 \neq u_2 \).

**Lemma 4.5.** Let \( \Omega \) be an open bounded subset of \( \mathbb{R}^2 \), \( \tilde{u} \) be a continuous positive bounded function on \( \Omega \) and
\[ \hat{W} = \{ u : \overline{\Omega} \to \mathbb{R} | u \text{ satisfies expression (4.9) and inequality (4.10)} \} \]
Let \( \hat{J} : \hat{W} \to C(\overline{\Omega}) \) be defined by
\[ \hat{J}(u) = \frac{\tilde{u}^2}{u^2} + 2 \ln u + F(\tilde{u}), \]
\( F(\tilde{u}) \) being a constant depending on \( \tilde{u} \). Then, \( \hat{J}(u) \) is strictly convex on \( \hat{W} \).

**Proof.** One easily verifies that \( \hat{W} \) is convex. Next for fixed constants \( c > 0 \) and \( c_1 \), consider the function \( F : (0, \sqrt{3c}) \to \mathbb{R} \) given by
\[ F(u) = \frac{c}{u^2} + 2 \ln u + c_1. \]
Since \( F''(u) = 2 \left( \frac{3c - u^2}{u^4} \right) > 0, \forall u \in (0, \sqrt{3c}) \), it follows from lemma 4.4 that \( F \) is strictly convex on \( (0, \sqrt{3c}) \). That is,
\[ F(\lambda u + (1 - \lambda)v) < \lambda F(u) + (1 - \lambda)F(v), \quad (4.12) \]
\( \forall u, v \in (0, \sqrt{3c}) \) and \( 0 < \lambda < 1 \). It follows from inequality (4.12) that for each \( w \in \Omega, c = \tilde{u}^2(w) \) and \( c_1 = F(\tilde{u}(w)), \forall u, v \in \hat{W} \) and \( 0 < \lambda < 1 \),
\[ \hat{J}(\lambda u(w) + (1 - \lambda)v(w)) < \lambda \hat{J}(u(w)) + (1 - \lambda)\hat{J}(v(w)), \]
which proves the lemma.
Remark For the functional

$$J(u) = \int \int_{\Omega} \left( \frac{\tilde{u}^2}{u^2} + 2 \ln u + \mathcal{F}(\tilde{u}) \right) dA,$$  \hspace{1cm} (4.13)$$

if $J(u)$ has a minimizer then theorem 4.3 and lemma 4.5 say $J(u)$ must has a unique minimizer.

**Theorem 4.6.** Let $\Omega$ be an open bounded subset of $\mathbb{R}^2$ with Lipschitz boundary. Given $\tilde{u} \in BV(\Omega)$ satisfying $0 < m \leq \tilde{u}(x,y) \leq M$, almost everywhere $(x,y) \in \Omega$, fix $s$, $1 < s < \sqrt{3}$,

$$W = \{ u \in BV(\Omega) : 0 < m \leq u(x,y) \leq s\tilde{u}(x,y), \text{ almost everywhere } (x,y) \in \Omega \} .$$

Let $E : W \to \mathbb{R}$ be given by

$$E(u) = \|Du\|(\Omega) + J(u),$$

where $J(u)$ is defined as equation (4.13). Then $E$ has a unique minimizer.

**Proof.** 1. **Prove the existence of the minimizer.**

Note first that by choice of $u$, $E(u)$ is defined for all $u \in W$. In fact we have

$$m_0 := \int \int_{\Omega} \left( \frac{m^2}{3M^2} + 2 \ln m + \mathcal{F}(\bar{u}) \right) dA$$

$$\leq \int \int_{\Omega} \left( \frac{\bar{u}^2}{u^2} + 2 \ln u + \mathcal{F}(\bar{u}) \right) dA$$

$$\leq \int \int_{\Omega} \left( \frac{M^2}{m^2} + 2 \ln M + \mathcal{F}(\bar{u}) \right) dA =: M_0.$$  \hspace{1cm} (4.14)$$

In particular, $J(u)$ is bounded below. Since $\|Du\|(\Omega) \geq 0$, then the functional $E(u)$ is bounded below. Thus there exists a sequence $\{u_n\}$ in $W$ minimizing $E$, that is

$$E(u_n) \to b := \inf \{ E(u) : u \in W \}.$$
We need to show that there exists \( u_0 \in W \) such that \( E(u_0) = b \).

Now as \( u_n \) minimizes \( E \), the sequence \( \{E(u_n)\} \) is bounded, hence the sequence \( \{\|Du_n\|(\Omega)\} \) is bounded. Also, \( \{\|u_n\|_{L^1(\Omega)}\} \) is bounded, in fact,

\[
m|\Omega| \leq \|u\|_{L^1(\Omega)} \leq M|\Omega|, \forall u \in W,
\]

where \( |\Omega| \) is an area of \( \Omega \). Hence, \( \{u_n\} \) is a bounded sequence in the norm of \( BV(\Omega) \). Thus by theorem 4.2, there exist \( u_0 \in BV(\Omega) \) and a subsequence \( \{u_{n_k}\} \) such that \( \{u_{n_k}\} \rightarrow u_0 \) in the norm \( \|\cdot\|_{L^1(\Omega)} \).

Since every convergent sequence in \( L^1(\Omega) \) possesses a subsequence converging pointwise almost everywhere, we may assume, replacing \( \{u_{n_k}\} \) by a suitable subsequence, that

\[
u_{n_k}(x, y) \rightarrow u_0(x, y), \text{ almost everywhere } \Omega.
\]

In particular,

\[
0 < m \leq u_0(x, y) \leq s\bar{u}(x, y), \text{ almost everywhere } \Omega
\]

and hence \( u_0 \in W \).

Now by theorem 4.1, and as \( \{u_{n_k}\} \) is bounded in \( BV(\Omega) \),

\[
\|Du_0\|(\Omega) \leq \lim_{k \to \infty} \|Du_{n_k}\|(\Omega). \tag{4.15}
\]

On the other hand, by expression (4.14) we can apply the Dominated Convergence Theorem to obtain that

\[
J(u_0) = \iint_{\Omega} \lim_{k \to \infty} \left( \frac{\tilde{u}^2}{u_{n_k}^2} + 2\ln u_{n_k} + \mathcal{F}(\tilde{u}) \right) dA
= \lim_{k \to \infty} \iint_{\Omega} \left( \frac{\tilde{u}^2}{u_{n_k}^2} + 2\ln u_{n_k} + \mathcal{F}(\tilde{u}) \right) dA
= \lim_{k \to \infty} J(u_{n_k}). \tag{4.16}
\]
Combining expression (4.15) and (4.16) then
\[ E(u_0) = J(u_0) + \|Du_0\|(\Omega) \]
\[ \leq \lim_{k \to \infty} J(u_{n_k}) + \lim_{k \to \infty} \|Du_{n_k}\|(\Omega) \]
\[ = \lim_{k \to \infty} E(u_{n_k}) = b \]
since the sequence \( \{u_n\} \) minimizes \( E \). This proves existence of a minimizer \( u_0 \).

2. Prove the uniqueness of the minimizer.

Observe that \( W \) is a convex set. By convexity of \( \|\nabla u\| \) and by lemma 4.5, it implies uniqueness of the minimizer of \( E(u) \).

4.3 Numerical Scheme

Consider the problem
\[
\frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta u^3} (\tilde{u}^2 - u^2), 
\]
(4.17)
where \( u(x, y, 0) \) is given and \( u = \tilde{u} \) on the boundary \( \partial \Omega \) of \( \Omega \) and \( \Omega \) is a unit rectangle. Here \( u = u(x, y, t) \) is a dependent variable, \( x, y, t \) are independent variables and \( \tilde{u}(x, y) \) is a given function of spatial variables \( x, y \). In order to solve problem (4.17) numerically, the spatial space of domain is considered as a square grid with \( N \) points width and \( N \) points height. The grid point \( (i, j) \) corresponds to location \( (x_i, y_j) \), \( i = 0 \ldots N - 1, j = 0 \ldots N - 1 \), where \( x_i = ih, y_j = jh \) and \( Nh = 1 \).

Denote \( u^n_{ij} = u(x_i, y_j, t_n) \) where \( t_n = n \Delta t, n = 0, 1, 2, \ldots \) and \( \Delta t \) is step size. Let \( u^0_{ij} = \tilde{u}_{ij} \), Rudin (1992) shows that the numerical scheme of problem (4.17) is
\[
u^{n+1}_{ij} = u^n_{ij} + \Delta t \left[ \frac{\Delta x}{h} \left( \frac{\Delta_x u^n_{ij}}{((\Delta_x u^n_{ij})^2 + (m(\Delta^x_{ij} u^n_{ij}, \Delta^y_{ij} u^n_{ij}))^2)^{1/2}} \right) \right] \\
+ \Delta t \left[ \frac{\Delta y}{h} \left( \frac{\Delta_y u^n_{ij}}{((\Delta_y u^n_{ij})^2 + (m(\Delta^x_{ij} u^n_{ij}, \Delta^y_{ij} u^n_{ij}))^2)^{1/2}} \right) \right] \\
+ \Delta t \left[ \frac{2}{\beta(u^n_{ij})^3} ((\tilde{u}_{ij})^2 - (u^n_{ij})^2) \right],
\]
(4.18)
with boundary conditions
\[ u^n_{0j} = \tilde{u}_{0j} \]
\[ u^n_{(N-1)j} = \tilde{u}_{(N-1)j} \]
\[ u^n_{i0} = \tilde{u}_{i0} \]
\[ u^n_{i(N-1)} = \tilde{u}_{i(N-1)} \]
where \( \Delta^x \Theta_{ij} = \pm(\Theta_{(i+1)j} - \Theta_{ij}) \) and similarly for \( \Delta^y \Theta_{ij} \), the step size \( \Delta t \) and \( h \) are chosen for stability such that
\[ \frac{\Delta t}{h} \leq 1, \]
\[ m(a, b) = \left( \frac{\text{sgn}(a) + \text{sgn}(b)}{2} \right) \min(|a|, |b|) \]
and
\[ \text{sgn}(x) = \begin{cases} 
-1 & \text{if } x < 0 \\
0 & \text{if } x = 0 \\
1 & \text{if } x > 0 
\end{cases} \]
Note that if \( u^n_{ij} \) converge as \( n \to \infty \), then \( \frac{u^{n+1}_{ij} - u^n_{ij}}{\Delta t} \to 0 \) as \( n \to \infty \).
Thus, the numerical solution of problem (4.18) will converge to the approximated solution of equation
\[ \frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta u^3} (\tilde{u}^2 - u^2) = 0, \]
where \( u = \tilde{u} \) on \( \partial \Omega \), which is the noiseless image of our model.

### 4.4 Numerical Results

To verify the theoretical part, we use some images in our experiments. The correlation coefficients of the original images and the noisy images are compared with the correlation coefficients of the original images and the reconstructed images.
First, speckle noise with 0.02 variance is added in the original pattern image by MATLAB software version 7.2. Correlation coefficients of the original image and the noisy image is 0.9678 while correlation coefficients of the original image and reconstructed images with respective to the number of iterative loops are shown in table 4.1. They are higher than 0.9678.

**Table 4.1 Correlation coefficients of reconstructed pattern images**

Furthermore, we use the Lenna image which is a well-known image in the field of image processing in our experiment. Speckle noise with 0.02 variance is added in the original image by MATLAB software. Similarly, correlation coefficients are compared and they are shown in table 4.2. The correlation coefficient of the original image and noisy image is 0.9444 while the correlation coefficients of the original image and reconstructed images are all higher.

We found that after enhancing the images by the numerical process, the correlation coefficient of the original image and reconstructed images are closer to 1 than the correlation coefficient of the original image and noisy images. This shows that the original image and the reconstructed images have better relationship and our result is claimed. The results show that the noise can be removed by the numerical process.

Additionally, if the correlation coefficients of the reconstructed images is used to compare the results of models, the proposed model provides better results than the results of ROF model and the model by Le et al.

The output of the prototype software shows that after enhancing the ultrasound image, one obtain a smoother image as presented in figure 4.9(a) and figure 4.9(b) which is 100-loops iterative process reconstructed ultrasound image.

4.5 Conclusion

A new model for speckle reduction of ultrasound images is presented. The model is minimizing the functional

$$E(u) = \beta \int \int_{\Omega} \left( \sqrt{u_x^2 + u_y^2} \right) dA + \int \int_{\Omega} \left( \frac{u^2}{u_x^2 + u_y^2} + 2 \ln u + \mathcal{F}(\tilde{u}) \right) dA,$$

where $\beta$ is a chosen parameter and $\mathcal{F}(\tilde{u})$ is a function of $\tilde{u}$. The model is based on calculus of variations which leads to the Euler-Lagrange differential equation:

$$\frac{\partial}{\partial x} \left( \frac{u_x}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{\partial}{\partial y} \left( \frac{u_y}{\sqrt{u_x^2 + u_y^2}} \right) + \frac{2}{\beta} u^3 (\tilde{u}^2 - u^2) = 0,$$

where $u = \tilde{u}$ on $\partial \Omega$ and approximation of the solution is by gradient descent method. Our technique can reduce the noise better than the ROF model. However, the result of the reconstructed images by our model are almost identical to the one by Le. The constraint is the processing time required. Moreover, because we work with the gray scale 256 bits mode, errors may arise from the rounding function in the software implementation.

APPENDICES
APPENDIX A

SPECKLE FILTERS IN RADAR IMAGING

speckle noise is present not only in ultrasound images, but also in the radar images. There are many researches dealing with speckle filter in the radar images. For example

1. Frost et al. filter (1982)

The speckle noisy image can be represented by the uncorrelated multiplicative model:

\[
\tilde{u}(x, y) = R(x, y) \cdot n(x, y), \quad (A.1)
\]

where \((x, y)\) are the spatial coordinate, \(\tilde{u}(x, y)\) is the observed image, \(n(x, y)\) is the white noise and \(R(x, y)\) is an autoregressive process\(^*\) with an autocorrelation function \(R_R(x, y)\):

\[
R_R(x, y) = \sigma_R^2 e^{-a \| (x, y) \|} + \bar{R}^2,
\]

where \(\bar{R}(x, y)\) is the image local mean, \(\sigma_R^2\) is the image local variance, \(a\) is the autocorrelation parameter and \(\| (x, y) \|\) is the norm of \((x, y)\).

There are several methods used for reducing the speckle noise which follow the above noise model and the method for the minimum mean square error\(^\dagger\)

---

\(^*\) **Autoregressive process** is a model which presents that the observed value \(x_t\) is determined by the values of \(x_{t-1}, \ldots, x_{t-p}\) or the \(p\)-observed values before \(x_t\). The autoregressive process can be written by

\[
x_t = c + \sum_{i=1}^{p} \varphi_i x_{t-i} + \varepsilon_t,
\]

where \(c\) is a constant, \(\varphi_i\) is called autocorrelation parameter and \(\varepsilon_t\) is error of process.

\(^\dagger\)The mean square error of the parameter \(u\) to approximate the parameter \(\hat{u}\) is given by the mean or expected value of \((u - \hat{u})^2\).
Frost presented the MMSE filter \( m(x, y) \) which is given by

\[
m(x, y) = K_2 \alpha e^{-\alpha \| (x, y) \|},
\]

where \( K_2 \) is a constant and

\[
\alpha^2 = a^2 + 2a \cdot \left( \frac{\pi}{\sigma_n} \right)^2 \left( 1 + \left( \frac{\pi}{\sigma_n} \right)^2 \right),
\]

where \( \pi \) is the mean of the noise and \( \sigma_n \) is the variance of the noise.

A simplification of the above filter leads to the loss of the parameter \( a \). The simplifier expression \( \alpha^2 = K \cdot C_u^2 \) is used. Hence the Frost filter is given by

\[
m(x, y) = K_1 e^{-KC_u^2(x_0, y_0) \| (x, y) \|},
\]

where \( K_1 \) is the filter parameter, \( C_u^2(x_0, y_0) \) is computed over an area centered at \((x_0, y_0)\) and \( K_1 \) is a normalizing constant which includes \( \alpha \).

2. Lee filter (1980)

The noisy image can be represented by an additive model also.

\[
\tilde{u}(x, y) = u(x, y) + n(x, y),
\]

where \( \tilde{u} \) is the considered image, \( u \) is a noiseless image, \( n \) is the additive noise.

Then, the linear MMSE filter is given by the following function \( \hat{u}(x, y) \),

\[
\hat{u}(x, y) = \overline{u}(x, y) + (\tilde{u}(x, y) - \overline{u}(x, y)) \left( \frac{\sigma_u^2(x, y)}{\sigma_u^2(x, y) + \sigma_n^2(x, y)} \right),
\]

where \( \overline{u} \) is the mean of \( \tilde{u} \), \( \sigma_u^2 \) and \( \sigma_n^2 \) is the variance of \( u \) and \( n \) respectively.
The Lee filter applies this linear MMSE filter for considering the multiplicative noise. It can be described in the form of weighted sum of the observed image and mean values:

\[
\hat{u}(x, y) = \bar{u}(x, y) \cdot W(x, y) + \bar{u}(x, y) \cdot (1 - W(x, y)), \tag{A.4}
\]

where the weight function \( W \) is given by

\[
W(x, y) = 1 - \frac{C_n^2}{C_u^2(x, y)},
\]

where \( C_n^2 = \frac{\sigma_n^2}{\Pi} \) and \( C_u^2 = \frac{\sigma_u^2}{\bar{u}} \) are the noise and image variation coefficients respectively.

3. **Kuan et al. filter (1985)**

Kuan presented a filter to deal with a linear MMSE filter for considering of the multiplicative noise just as the Lee filter. This filter is written by (A.4) with the weight function

\[
W(x, y) = 1 - \frac{C_n^2}{C_u^2(x, y)}.
\]

4. **Homomorphic Filter**

Arsenals (1984) and Yan and Chen (1986) also used the multiplicative speckle noise model shown in equation (A.1). A logarithmic transformation is performed to obtain the additive noise model by

\[
\ln \tilde{u}(x, y) = \ln R(x, y) + \ln n(x, y).
\]

Then, the linear MMSE filter in equation (A.3) is used for this noise model.
APPENDIX B

PROTOTYPE SOFTWARE

B.1 Prototype Software

The Prototype software is developed for the experiment. It is implemented in the *Pascal language* on *Borland Delphi* version 6. In order to work with the video files, the additional library *Mitov software VideoLab* version 3.1 is installed.

![Figure B.1](image)

*Figure B.1* The figure of prototype software and its components.

As show in figure B.1, the software components are as follows;

1. **Original video displayer**

   The original video is shown on the left displayer.

2. **Reconstructed video displayer**

   The reconstructed video is shown on the right displayer.
3. **Pause button**

The video is paused if this button is clicked.

4. **Resume button**

The paused video is resumed if this button is clicked.

5. **Exit button**

This button is used for the program closing.

6. **Step size text field**

The step size is filled in the text field and then the OK button is used for the activation.

7. **OK button**

This button is used for activating of the step size in text field.

8. **Iterative label**

The number of iterative loops is labeled in this component.

9. **Up button**

When the increasing of the reconstructed iteration loops is required, this button is used.

10. **Down button**

Converse from Up button, if the decreasing of the reconstructed iteration loops is required, this button is used.

### B.2 Source Code

Source code is composed by two classes.
1. Main class.

This part is used for initialization all of the modules, components and variable of the form. This class is the first part working when the program is execute and run.

```pascal
program Project1;

uses
    Forms,
    Unit1 in 'Unit1.pas' {Form1};

begin
    Application.Initialize;
    Application.CreateForm(TForm1, Form1);
    Application.Run;
end.
```

2. Computational class.

The computational part dealing with the numerical scheme include the display part is implemented in this class.

```pascal
unit Unit1;

interface

uses
    Windows, Messages, SysUtils, Variants,
```

CURRICULUM VITAE

FIRST NAME: Watchirawoot   LAST NAME: Seekot

GENDER: Male   NATIONALITY: Thai   DATE OF BIRTH: June 22, 1983

EDUCATION BACKGROUND:

- Bachelor of Science in Computer Science (Second Class Honours),
  May 26, 2002 - March 29, 2006,
  Khonkaen University, Khonkaen, Thailand.

WORK EXPERIENCES:

- Teaching Assistant in Calculus I, II and III, School of Mathematics, Suranaree University of Technology.

- Teaching Assistant in Business Mathematics I and II, School of Management Technology, Suranaree University of Technology.

PUBLICATION:

- Seekot, W. and Tanthamuch, J. (In Press). ULTRASOUND IMAGE ENHANCEMENT BY MEANS OF A VARIATIONAL APPROACH,
  Proceedings of 11th National Graduate Conference, Valaya Alongkorn Rajabhat University.

SCHOLARSHIPS AND AWARDS:

- Scholarship for the promising graduate students, academic year 2006 - 2007, Suranaree University of Technology.

- Good oral presentation award, 11th National Graduate Conference, December 17 - 18, 2008, Valaya Alongkorn Rajabhat University.
