กิตติพงศ์ ไชยนอก : การสังเคราะห์และศึกษาโครงสร้างของสารประกอบนาโนรูปผสม อินทรีย์-อนินทรีย์ (SYNTHESIS AND STRUCTURAL STUDIES OF HYBRID ORGANIC-INORGANIC NANOCOMPOSITES) อาจารย์ที่ปรึกษา :

รองศาสตราจารย์ ดร. เค็นเนท เจ. แฮลเลอร์, 407 หน้า.
วิทยานิพนธ์นี้ นำเสนอเกี่ยวกับการสังเคราะห์และศึกษาโครงสร้างผลึกเชิงเดี่ยวของสาร ประกอบนาโนรูปผสมอินทรีย์-อนินทรีย์ โดยส่วนที่หนึ่งของวิทยานิพนธ์กล่าวถึง การใช้หลักการ วิศวกรรมผลึกและเคมีซูปราโมเลคูลาร์ เพื่อสังเคราะห์โครงสร้างใหม่ของวัสดุรูปผสมจำพวกสาร ประกอบโคออร์ดิเนชันโพลิเมอร์ที่มีหมู่ไซยาโน สารประกอบเชิงซ้อนไซยาโน และลิแกนด์ของ ออร์กาโนไซยาโนอยู่ในโครงสร้างผลึก พร้อมทั้งอธิบายความสัมพันธ์ระหว่างโครงสร้างและสม บัติแม่เหล็กของสารประกอบดังกล่าว

พบว่าเมื่อใช้สารประกอบเชิงซ้อนเตตระไซยาโนเฟอร์เรตของ $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4}\right]$ เป็นสารตั้งต้น โดยที่ L คือ ลิแกนด์ไบเดนเทต ได้สังเคราะห์สารประกอบจำพวกเฟอร์โรแมกเนติคที่มีโครงสร้าง แบบสองมิติลักษณะคล้ายลูกฟูกของ $\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Mn}\right] \cdot \mathrm{MeOH}$ และโครงสร้างแบบท่อนาโน หนึ่งมิติของ $\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ รวมทั้งสารประกอบจำพวกแอนไทเฟอร์โรแมกเนติค ประกอบด้วยสารประกอบที่มีโครงสร้างคล้ายสี่เหลี่ยมจัตุรัสของ $\left[\mathrm{Fe}(1,10-\mathrm{phen})(\mathrm{CN})_{4} \mathrm{Cu}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ $\cdot 5 \mathrm{H}_{2} \mathrm{O}$ และ $\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Cu}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}$ และสารประกอบที่มีโครงสร้างแบบหนึ่งมิติลักษณะ คล้ายโซ่ฟันปลาของ $\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right] \cdot \operatorname{solvent}$ ขณะที่โมเลกุลเป็นเส้นตรงของสารประ กอบเชิงซ้อนไดไซยาโนอาร์เจนเตท $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$ถูกใช้เป็นบริดจิงลิแกนด์ที่ยาวกว่าเพื่อแทนที่หมู่ ไซยาไนด์ของสารประกอบเชิงซ้อน $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4}\right]$ ข้างต้น ได้สังเคราะห์สารประกอบซูปราโมเลคู ลาร์ใหม่ของ $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ และ $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathrm{Mn}\left(2,2^{\prime} \text {-bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ ซึ่ง แสดงสมบัติแม่เหล็กชนิดแอนไทเฟอร์โรแมกเนติค และสารประกอบโคออร์ดิเนชันโพลิเมอร์ใหม่ ที่มีโครงสร้างแบบหนึ่งมิติคล้ายบันไดของ $\left[\mathrm{Ag}_{4}(\mathrm{CN})_{7}\left\{\mathrm{Cd}\left(2,2^{\prime}-\mathrm{bipy}\right)\right\}_{2}\right]\left[\mathrm{ClO}_{4}\right]$ และโครงสร้างแบบ สามมิติของ $\left[\left\{\operatorname{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Cd}\left(2,2^{\prime}-\mathrm{bipy}\right)\right]$ นอกจากนี้ยังพบว่าเมื่อใช้สารประกอบเชิงซ้อนทรงสี่ เหลี่ยมจัตุรัสแบนราบของเตตระไซยาโนนิกเกิลเลต $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ เป็นลิแกนด์ ได้สังเคราะห์สาร ประกอบใหม่ที่มีโครงผลึกร่างตาข่ายแบบสามมิติของ $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ และ $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right]$ $\cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeOH}$ ซึ่งทั้งสองสารประกอบนี้แสดงสมบัติแม่เหล็กชนิดเดียวกันคือ แอนไทเฟอร์โรแมก เนติค ขณะที่ลิแกนด์ออร์กาโนไดไนไตร์ของ ACCN และ AIBN ถูกใช้เพื่อเป็นบริดจิงลิแกนด์ใน การศึกษาการเกิดโครงผลึกร่างตาข่ายแบบสามมิติของสารประกอบเหล็ก (II) โคออร์ดิเนชันโพลิ เมอร์ของ $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]\left[\mathrm{InCl}_{4}\right]_{2}\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]\left[\mathrm{FeCl}_{4}\right]_{2}\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]\left[\mathrm{InCl}_{4}\right]_{2}$ และ $\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]\left[\mathrm{FeCl}_{4}\right]_{2}$ พบว่าโครงสร้างผลึกของสารประกอบดังกล่าว มีลักษณะคล้ายกับโครงผลึกร่างตาข่ายแบบสามมิติ

ของแอลฟา-พอโลเนียม โดยที่ผลึกของสารประกอบ AIBN อยู่ในระบบที่มีสมมาตรสูงของหมู่ปริ ภูมิ $R \overline{3}$ และแสดงการเปลี่ยนแปลงสมบัติทางแม่เหล็กเนื่องจากผลของอุณหภูมิ โดยเกิดการแทรน ซิชันชนิดไม่สมบูรณ์แบบ "ครึ่ง" สปิน-ครอสส์โอเวอร์ ส่วนสารประกอบ ACCN พบว่าผลึกอยู่ใน ระบบสมมาตรที่ต่ำกว่าสารประกอบ AIBN ซึ่งอยู่ในหมู่ปริภูมิ $P \overline{1}$ และไม่แสดงการเกิดแทรนซิ ชันแบบสปิน-ครอสส์โอเวอร์ นอกจากนี้ยังได้ศึกษาและอธิบายการเกิดโครงสร้างซูปราโมเลคูลาร์ ใหม่ของสารประกอบโคออร์ดิเนชันโพลิเมอร์ซิลเวอร์ (I) ไอออนและลิแกนด์ bmtz $\mathrm{H}_{2} \mathrm{bmtz}$ และ bptz อีกด้วย

ส่วนที่สองของวิทยานิพนธ์นี้ กล่าวถึงการสังเคราะห์โครงสร้างผลึกใหม่ของวัสดูรูปผสม โลหะออกไซด์เพื่อเปรียบเทียบกับวัสดุจำพวกซีโอไลต์ สารประกอบใหม่ทั้งห้าของโลหะแทรนซิ ชันเวนาเดตซึ่งถูกดัดแปลงด้วยสารอินทรีย์ สามารถสังเคราะห์ได้ด้วยวิธีไฮโดร/โซลโวเทอร์มัล โดยสารประกอบที่มีสารอินทรีย์ทำหน้าที่เหมือนเป็นเทมเพลทในโครงสร้างผลึก พบในโครงสร้าง แบบสามมิติของ $[\mathrm{ImH}]\left[\mathrm{Mn}_{3}(\mathrm{OH})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right]$ ขณะที่สารประกอบของ $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ เมื่อ M คือ แมงกานีส โคบอล์ต หรือ นิกเกิล และสารประกอบของ $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO}) \mathrm{V}_{2} \mathrm{O}_{6}\right]$ มีโครงสร้างแบบ ชั้นสองมิติ และพบว่าสารประกอบ $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ เกิดการเปลี่ยนวัฏภาคแบบออร์เดอร์-ดิสออร์ เดอร์ของหมู่ปริภูมิเนื่องด้วยผลของอุณหภูมิ โดยเกิดขึ้นระหว่างหมู่ปริภูมิที่ดิสออร์เดอร์ของ $P 4_{2} / n$ ณ อุณหภูมิ 295 เคลวิล และหมู่ปริภูมิที่ออร์เดอร์ของ $I 4_{1} / a$ (แมงกานีส และ โคบอล์ต) หรือ $P 2 / n$ (นิกเกิล) ณ อุณหภูมิ 100 เคลวิล สำหรับสารประกอบ $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO}) \mathrm{V}_{2} \mathrm{O}_{6}\right]$ การถูกแทนที่ ณ ตำแหน่งอิคอทอเรีลหนึ่งตำแหน่งของหมู่อิมิดาโซลบนรูปทรงออกตะฮีดรัลที่บิดเบี้ยวของแมงกา นีส(II) ด้วยโมเลกุลของไดเมทิลซัลฟอกไซด์ ทำให้โครงสร้างผลึกเสียสมมาตร ส่งผลให้เกิดการ เปลี่ยนหมู่ปริภูมิจาก $P 4_{2} / n$ ในสารประกอบ $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ ไปสู่หมู่ปริภูมิที่มีสมมาตรต่ำกว่าของ $P 2_{1} / n$ ณ อุณหภูมิ 295 เคลวิล อย่างไรก็ตามโครงผลึกร่างตาข่ายออกไซด์ของโลหะในสารประกอบ $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO}) \mathrm{V}_{2} \mathrm{O}_{6}\right]$ ยังคงมีลักษณะคล้ายๆ กับที่พบในสารประกอบของ $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$

KITTIPONG CHAINOK : SYNTHESIS AND STRUCTURAL STUDIES
OF HYBRID ORGANIC-INORGANIC NANOCOMPOSITES. THESIS
ADVISOR: ASSOC. PROF. KENNETH J. HALLER, Ph.D. 407 PP.

COORDINATION POLYMERS/CRYSTAL ENGINEERING/HYBRID ORGANICINORGANIC/MAGNETIC PROPERTIES/SUPRAMOLECULAR/VANADATES

This thesis focuses on the single crystal growth and solid state structural studies of new hybrid organic-inorganic nanocomposites. The first part of this thesis deals with a rational synthetic strategy using the principles of crystal engineering and supramolecular chemistry for the construction of new hybrid coordination polymers containing cyano, metallocyano and organocyano bridging groups, and correlations between their structural and magnetic properties are described.

The use of tetracyanoferrate complexes of the type $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4}\right]$ as building blocks, where L is a bidentate ligand, two new ferromagnetic compounds with either a 2-D corrugated sheet structure, $\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Mn}\right] \cdot \mathrm{MeOH}$ or a 1-D nanotubelike structure, $\left[\mathrm{Fe}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$, three antiferromagnetic compounds containing molecular square structures, $\left[\mathrm{Fe}(1,10-\mathrm{phen})(\mathrm{CN})_{4} \mathrm{Cu}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 5 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Cu}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}$, and 1-D zigzag chains $\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right]$ -solvent were synthesized. The linear $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$was used as a longer bridging ligand to replace the CN groups of the $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]$ building block. Two new supramolecular structures, $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathrm{Mn}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ with display a weak antiferromagnetic behavior, and two new coordination polymers 1-D ladder-chains $\left[\mathrm{Ag}_{4}(\mathrm{CN})_{7}\left\{\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right\}_{2}\right]\left[\mathrm{ClO}_{4}\right]$ and triple interpenetrated 3-D $\left[\left\{\operatorname{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Cd}\left(2,2^{\prime}\right.\right.$-bipy $\left.)\right]$ were synthesized. Two new antiferromagnetic compounds composed of 3-D cyanide-bridged homometallic networks of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeOH}$ were synthe-
sized by using the square planar ligand complex $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$.
The 2-connecting organodinitrile ligands ACCN and AIBN were used as bridging ligands for investigations of self-assembly processes in the construction of novel $\mathrm{Fe}(\mathrm{II})$ coordination polymer compounds: $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]\left[\mathrm{InCl}_{4}\right]_{2}$, $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]$ $\left[\mathrm{FeCl}_{4}\right]_{2},\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]\left[\operatorname{InCl}_{4}\right]_{2}$, and $\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]\left[\mathrm{FeCl}_{4}\right]_{2}$. The crystal structures consisted of 3-D $\alpha$-Po like nets. The AIBN compounds crystallize in a highly symmetrical $R \overline{3}$ phase, and are display an interesting incomplete "half" spincrossover (SCO). The ACCN compounds crystallize in a lower symmetrical $P \overline{1}$ phase, and no SCO transitions are observed. In addition, novel supramolecular architectures of $\mathrm{Ag}(\mathrm{I})$ coordination polymers formed with the multimodal ligands of bmtz, $\mathrm{H}_{2} \mathrm{bmtz}$, and bptz are also described.

The second aim of this thesis is to explore new metal oxide solid materials as analogues of zeolites. Five new organically modified transition metal vanadate compounds were hydro/solvothermally synthesized. The organic "templating" effect is well illustrated by the 3-D solid $[\mathrm{ImH}]\left[\mathrm{Mn}_{3}(\mathrm{OH})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right]$. Isostructural compounds of formula $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$, where M is $\mathrm{Mn}, \mathrm{Co}, \mathrm{Ni}$, and $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO})\right.$ $\left.\mathrm{V}_{2} \mathrm{O}_{6}\right]$ have 2-D layer structure. Isostructural species $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ are display an interesting order-disorder crystallographic phase transition between the $P 4_{2} / n$ at 295 K and $I 4_{1} / a(\mathrm{Mn}$ and Co$)$ or $P 2 / n(\mathrm{Ni})$ space groups at 100 K . For compound $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO}) \mathrm{V}_{2} \mathrm{O}_{6}\right]$, the replacement of one equatorial imidazole on $\mathrm{Mn}(\mathrm{II})$ with a covalently coordinated DMSO results in a loss of symmetry from the parent $P 4_{2} / n$ structure in isostructural compounds, lowering the space group to $P 2_{1} / n$ at 295 K , but the topology of bimetallic oxide framework is otherwise similar.

## ACKNOWLEDGEMENTS

Although I am indeed the sole author of this thesis, I am by no means the sole contributor. So many people have contributed to my thesis, to my education and to my life, and it is now my great pleasure to take this opportunity to thank them.

Firstly, I would like to gratefully thank my principal advisor, Assoc. Prof. Dr. Kenneth J. Haller for the unique opportunity to accomplish both M.Sc. and Ph.D degrees with him, his patience and knowledge whilst allowing me the room to work in my own way, and for offering several precious opportunities to attend and to make presentations in national and international academic conferences. I appreciate his manner of scientific thinking and his assistance in writing reports (i.e. grant proposals and scholarship applications).

Secondly, very special thanks are due to my co-supervisors at Monash University, Prof. Dr. Keith S. Murray and Assoc. Prof. Dr. Stuart R. Batten. I don't believe there are enough appropriate words to adequately thank them for the great support they have given to me. I am impressed by their scholarly performance, modesty and prudence, kindness and generosity, generous financial support, encouragement, discussion, sound advice, good teaching, good company, lots of good ideas, intensive proof reading of this thesis and friendship. These have been invaluable on both an academic and a personal level. I have learnt a lot from them. I will forever be proud for having worked under their guidance.

I am also very grateful to my co-supervisor at Research School of Chemistry, The Australian National University, Prof. Dr. A. David Rae, for his encouragement,
sound advice and good teaching me some nonroutine crystallography and proof reading many drafts of manuscript. Thanks to his least squares refinement program, RAELS. To Annas Rae (his wife), thanks for her help in taking care of me, when I was in Canberra and Sydney. I would like to thank Prof. Dr. Ray L. Withers, Dr. Lasse Norén and Dr. Yun Liu for organizing the solid state group at the Research School of Chemistry. I also thank Dr. Binh Nguyen for friendship and support.

I extend my warm and sincere thanks to Prof. Dr. Ian D. Williams for his continuous support of my work on vanadate project, encouragement and constant guidance during the course of my research at Hong Kong University of Science nd Technology.

I would like to thank Dr. Suzanne Neville and Dr. Craig Forsyth (Monash University), Dr. Anthony Willis (ANU), and Dr. Herman Sung (HKUST), for help in collecting the data of single crystal X-ray, good sound advice and good teaching. I have learnt a lot from them.

To Dr. Boujemaa Moubaraki, thank you for your help with the SQUID magnetic measurements, useful discussion, good sound advice and good teaching, and friendship throughout the duration of the project in Monash University. I would also like to thank Assoc. Prof. Dr. John D. Cashion (Physics, Monash University) for help with Mössbauer spectra measurement, sound advice and good teaching.

I am very grateful to the Australian Government Department of Education, Science and Training (DEST) for providing financial support for undertaking research at Monash University and The Australian National University under the 2006 Endeavour Asia Award and the 2007 Endeavour Research Fellowship.

I would like to thanks the International Union of Crystallography for a

Bursary Award to support my attendance at XX Congress (IUCr2005) in Florence, Italy. I would also like to thanks the Society of Crystallographers in Australia and New Zealand for financial support of my attendance at SCANZ 2007 ConferenceCrystal XXV, Hunter Valley, New South Wales, Australia.

I would like to thank the Liverpool Materials and Chemistry Group Portfolio Partnership for financial support to attend the summer school and workshops on Porous Materials, University California, Santa Barbara. USA. Also, thanks to Suranaree University of Technology for financial support of my attendance at the $31^{\text {st }}$ and $34^{\text {th }}$ STT conferences and the $6^{\text {th }}$ NSGR, Thailand.

My best regards I sincerely give to who were my Australian Government of DEST advisors during the period of undertaking research in Australia, Ms. Cynthia Grant (Endeavour Project Manager), Ms. Mary Dykes (Endeavour Case Manager), Mr. Denise Miles (Endeavour Project Co-ordinator), for their suggestions, encouragement and friendship.

I am profoundly grateful to the official referees of this thesis, Assoc. Prof. Dr. Malee Tangsathitkulchai (chairperson), Assoc. Prof. Dr. Adrian E. Flood, Assoc. Prof. Dr. Albert Schulte and Asst. Prof. Dr. Korakot Nawakhun, for their constructive criticism, valuable suggestions and sparing their precious time for examining my thesis.

To former and current Haller group members: Dr. Auphatham Phothikanith, Dr. Preeyaporn Pookrod, Dr. Weenawan Somphon, Angkana Kiatpichitpong, Angkana Chatkon, Winya Dungkaew, Nongnaphat Khosavithikul, Samroeng Krachodnok, Saiphon Chanpaka, Ratchadaporn Puntharod, Kasada Sala, Pushpakumara Herath, Orrasa In-noi, Oratai Saisa-ard, Jittima Thisuwan, and Saifon

Kohnhorst, I would like to thank for their constant encouragement and helping me get through the difficult times.

Many thanks to former and current Murray and Batten group members: Dr. Boujemaa Moubaraki, Dr. Suzanne Neville, Dr. Jinzhen Lu, Dr. David Turner, Dr. Stuart Langley, Dr. Martin Duriska, Caspar Schneider, Tamsyn Ross, Ponco Prananto, and Anthony Chesman, for the very nice co-operation. It has always been a pleasure time to do experiments and discuss work together with them.

To former and current Williams members, especially to Dr. Fanny Shek, Dr. Alex Au-Yeung, and Pokka Pang, for their help and suggestions with the laboratory work in hydrothermal synthesis and friendship.

To Anchalee Suttikomala, thank you very much for support and time in sharing our faith. Also, to my dear brother, Winya Dungkaew and his girlfriend, Kamolwan Wichai, thanks for their constant encouragement and support during my Ph.D. candidature, especially at difficult moments.

I am indebted to my many student colleagues for providing a stimulating and fun environment in which to learn and grow. I wish to thank my best friend as an undergraduate (especially to Supakit Satkeaw) and my best friend as a graduate student (especially to Suparat Waranon, Sirinuch Loiha, Pongthanawat Khemtong, Surachai Artkla, Sittichai Kulawong, and Pairin Suwannasri) for all the emotional support, camaraderie, entertainment and caring they provided.

Last, but by no means least, I am deeply indebted to my parents, my brothers, and sisters for their support, patience and love, and I thank everyone for good chemistry and bad chemistry; you cannot create and develop without both.

## LIST OF TABLES

Tables Page
1.1 The van der Waals Radii used for observing hydrogen bonds ..... 14
1.2 Classification and properties of hydrogen bonds ..... 19
1.3 Some selected examples of possible prototypes ..... 29
1.4 Comparison of calculated spin-only magnetic moments with experimental data for some octahedral complexes ..... 37
1.5 Summary of different types of magnetic behavior ..... 42
1.6 Experimental methods for monitoring the SCO in $\mathrm{Fe}(\mathrm{II})$ compounds ..... 46
1.7 Selected examples and applications of inorganic oxides ..... 64
2.1 Summary of crystallographic data for the compounds $\mathbf{2 a}-\mathbf{2 f}$ ..... 99
2.2 Selected bond lengths and angles for 2a ..... 100
2.3 Selected bond lengths and angles for 2b ..... 101
2.4 Selected bond lengths and angles for 2c and 2d ..... 102
2.5 Selected bond lengths and angles for $\mathbf{2 e}$ ..... 103
2.6 Hydrogen bond geometries for $\mathbf{2 a}$ and $\mathbf{2 b}$ ..... 109
2.7 Geometrical parameters of $\pi-\pi$ interactions for $\mathbf{2 a}$ and $\mathbf{2 b}$ ..... 110
2.8 Anion- $\pi$ interactions for $2 \mathbf{2 a}$ and $\mathbf{2 b}$ ..... 110
2.9 Intra- and intermolecular interactions for 2c and 2d ..... 119
2.10 Geometrical parameters of $\pi-\pi$ interactions for $\mathbf{2 c}$ ..... 119
2.11 Hydrogen bond geometries for $\mathbf{2 e}$ and $\mathbf{2 f}$ ..... 127
2.12 Geometrical parameters of $\pi-\pi$ interactions for $\mathbf{2 e}$ and $\mathbf{2 f}$ ..... 128
2.13 Anion- $\pi$ interactions for $2 \mathbf{e}$ and $\mathbf{2 f}$ ..... 129

## LIST OF TABLES (Continued)

Page3.1 Summary of crystallographic data for 3a-3c and 3e ..... 147
3.2 Selected bond lengths and angles for 3a ..... 148
3.3 Selected bond lengths and angles for $\mathbf{3 b}$ ..... 150
3.4 Selected bond lengths and angles for 3c ..... 151
3.5 Selected bond lengths and angles for $3 \mathbf{e}$ ..... 152
3.6 Vibrational frequencies of the
cyanide ligand in the present study ..... 156
3.7 Hydrogen bond geometries for 3a ..... 163
3.8 Geometrical parameters of $\pi-\pi$ interactions in 3a ..... 163
3.9 Hydrogen bond geometries for 3c ..... 176
3.10 Geometrical parameters of $\pi-\pi$ interactions in 3c ..... 177
4.1 Summary of crystallographic data for the compounds $\mathbf{4 a}-\mathbf{4 d}$ ..... 209
4.2 Selected bond lengths and angles for $\mathbf{4 a}$ and $\mathbf{4 b}$ ..... 210
4.3 Selected bond lengths and angles for $\mathbf{4 c}$ ..... 211
4.4 Selected bond lengths and angles for $4 d$ ..... 212
4.5 Hydrogen bond geometries for $\mathbf{4 a}$ and $\mathbf{4 b}$ ..... 213
4.6 Geometrical parameters of $\pi-\pi$ interactions in $\mathbf{4 a}-\mathbf{4 d}$ ..... 214
5.1 Summary of crystallographic data for the compounds $\mathbf{5 a}$ and $\mathbf{5 b}$ ..... 250
5.2 Selected bond lengths and angles for $\mathbf{5 a}$ and $\mathbf{5 b}$ ..... 251
5.3 Hydrogen bond geometries for $\mathbf{5 a}$ and $\mathbf{5 b}$ ..... 252
5.4 Vibrational frequencies for compounds $\mathbf{5 a}$ and $\mathbf{5 b}$ ..... 269
6.1 Summary of crystallographic data for the compounds $\mathbf{6 a - 6 b}$ ..... 287

## LIST OF TABLES (Continued)

Tables Page
6.2 Summary of crystallographic data for the compounds $\mathbf{6 c - 6 e}$ ..... 288
6.3 Selected bond lengths and angles for $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]^{2+}$ cations in $\mathbf{6 a}$ and $\mathbf{6 b}$ at selected temperatures ..... 289
6.4 Selected bond lengths and angles for $\left[\mathrm{Fe}(\mathrm{AIBN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{2+}$ cations of $\left[\mathrm{Fe}(\mathrm{AIBN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left[\mathrm{FeCl}_{4}\right]_{2}, 6 \mathrm{c}$ at 123 K ..... 290
6.5 Hydrogen bond geometries
for $\left[\mathrm{Fe}(\mathrm{AIBN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left[\mathrm{FeCl}_{4}\right], \mathbf{6 c}$ ..... 290
6.6 Selected bond lengths and angles for $\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]^{2+}$ cations in $\mathbf{6 d}$ and $\mathbf{6 e}$ at selected temperatures ..... 291
6.7 Mössbauer data for $\left[\operatorname{Fe}(\mathrm{AIBN})_{3}\right]\left[\mathrm{MCl}_{4}\right]_{2}, \mathrm{M}=\operatorname{In}(\mathbf{6 a}), \mathrm{Fe}(\mathbf{6 b})$ ..... 319
7.1 Summary of crystallographic data for the compounds 7a and 7e ..... 337
7.2 Summary of crystallographic data
for the compound $\mathbf{7 b}$ at selected temperatures ..... 338
7.3 Summary of crystallographic data for the compound $\mathbf{7 c}$ at selected temperatures ..... 339
7.4 Summary of crystallographic data for the compound $7 \mathbf{d}$ at 100 and 295 K ..... 340
7.5 Refinement statistics for the compounds $\mathbf{7 b}-7 \mathbf{d}$ at selected temperatures ..... 341
7.6 Selected bond lengths for 7a ..... 346
7.7 Largest principal libration values for the imidazoles
of the low temperature phase ..... 363

## LIST OF TABLES (Continued)

## Tables

Page
7.8 Largest principal libration values
for the imidazoles of the high temperature phase364
7.9 Departure from equivalence of pseudo symmetry related imidazoles for the low temperature phase ..... 364
7.10 Departure from equivalence of pseudo symmetry related imidazoles for the high temperature phase ..... 364
7.11 Selected bond lengths of $7 \mathbf{b}$ and $7 \mathbf{c}$ at 100 K ..... 367
7.12 Selected bond lengths of $7 \mathbf{d}$ at 100 K ..... 368
7.13 Hydrogen bond geometries
for $7 \mathbf{b}$ and $7 \mathbf{c}$ at 100 and 295 K ..... 369
7.14 Hydrogen bond geometries for $7 \mathbf{d}$ at 100 and 295 K ..... 370
7.14 Hydrogen bond geometries for $\mathbf{7 e}$ ..... 373

## LIST OF FIGURES

Figures Page
1.1 Occurrence of the term hybrids organic-inorganic in titles of papers published between 1995 and 2007 ..... 2
1.2 Self-assembly of the circular helicate $\left[\left(\mathrm{Fe}_{5} \mathrm{~L}_{5}\right) \mathrm{Cl}\right]^{9+}$ from five tris-bpy ligand ..... 4
1.3 Guest inclusion/removal in $\left[\mathrm{Fe}_{2}(\text { azpy })_{4}(\mathrm{NCS})_{4}\right]$ •(guest) ..... 6
1.4 Self-assembly of nanosize coordination cages ..... 8
1.5 (a) Ball-wires-sticks and (b) space-filling representations of the hexameric coordination capsule ..... 9
1.6 View of the hexagonal packing of tubules composed of $p$-sulfonatocalix-[4]arene with intercalated pyridine $N$-oxide ..... 10
1.7 (a) Ball-stick and (b) space filling model showing ion-dipole interactions in the cesium complex of [18]crown-6 ..... 12
1.8 Hydrogen bond geometry and partial charges ..... 14
1.9 Structures of common hydrogen bond types ..... 15
1.10 View of honeycomb hydrogen bonds sheets in $\left[\mathrm{Ni}(\mathrm{Hbim})_{3}\right]^{-}$building block ..... 16
1.11 Schematic representation of (a) attractive and
(b) repulsion of secondary hydrogen bonds interactions ..... 17
1.12 (a) Ball-stick and (b) space filling representations of the enforced self-assembly of molecules of pyrido[4,3-dpyrimidine] into a hexamer ..... 18

## LIST OF FIGURES (Continued)

Figures Page
1.13 Cation $-\pi$ interactions between benzene and a potassium cation ..... 20
1.14 (a) Ball-stick and (b) space-filling representations, showing anion $-\pi$ interactions in $\left[\left\{\mathrm{Ni}_{5}(\mathrm{bptz})_{5} \subset\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{10}\right\} \mathrm{SbF}_{6}\right]\left(\mathrm{SbF}_{6}\right)_{9}$ ..... 21
1.15 Schematic representations of aromatic-aromatic interactions ..... 22
$1.16 \pi-\pi$ interactions between sym-triphenethynyl- benzene and sym-tris(perfluorophenethynyl)benzene ..... 24
1.17 Some of the simplest infinite 3-D nets ..... 28
1.18 Coordination polymers compounds formed by the 4,4'-bipy bridging ligand with difference metal centers ..... 31
1.19 2-D representation of spin ..... 40
1.20 Schematic illustration of the magnetization, $M$, as a function of applied magnetic field, $H$ ..... 41
1.21 Schematic illustration of an Fe (II) SCO complex ..... 44
1.22 Various types of SCO transition ..... 45
1.23 Typical temperature evolution of
(a) Mössbauer, (b) infrared, and (c) electronic d-d visible spectra for a SCO system of Fe (II) ..... 47
1.24 (a) Coordination environment of $\mathrm{Fe}(\mathrm{II})$ ions and (b) a schematic presentation of the 3-D
$\alpha$-Po like network in $\left[\left\{\mathrm{Fe}(\mathrm{pbtz})_{3}\right\}\left(\mathrm{ClO}_{4}\right)_{2}\right] \cdot 2 \mathrm{EtOH}$ ..... 49
1.25 A schematic presentation of the 3-D cubic network in Prussian blue ..... 51

## LIST OF FIGURES (Continued)

## Figures

Page
1.26 Perspective view of a
fragment of the 4,2-ribbon like chain in $\left[\left\{\mathrm{Fe}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right\}_{2}\left\{\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right\}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{M}=\mathrm{Co}$ and Cu ........................... 54
1.27 (a) Side and (b) top views of
a CNT-like coordination hexagonal tube structure in $\left[\mathrm{Ru}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$........................................... 57
1.28 Perspective view of the structure of cyanide-bridged bimetallic, 3-D Hofmann-like networks in $\left[\mathrm{Pt}(\mathrm{CN})_{4} \mathrm{Fe}(\mathrm{pyz})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$................................ 59
1.29 (a) A fragment in $\left[\mathrm{Fe}(3-\mathrm{I}-\mathrm{py})_{2}\left\{\mathrm{Au}(\mathrm{CN})_{2}\right\}_{2}\right] \cdot 0.5(3-\mathrm{I}-\mathrm{py})$
(b) packing with emphasizing the aurophilic interactions .............................. 61
1.30 Metamorphosis of the vanadium coordination polyhedra ............................... 65
1.31 Polyhedral and ball-stick
representations in $\left[\mathrm{H}_{2} \mathrm{en}\right]\left[\mathrm{Mn}_{3}\left(\mathrm{~V}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$.............................................. 67
2.1 (a) Thermal ellipsoid plot of a fragment and (b)
coordination environments of the metal centres of 2a ................................. 105
2.2 (a) Packing diagram for $\mathbf{2 a}$ viewed down showing anion $\cdots \pi$ and $\mathrm{Ag} \cdots \pi$ interactions and (b) the shortest contacts between perchlorate anions and the pyrimidine or tetrazine rings and Ag ions .......... 106

2.3 Space-filling representations for 2a project

Slightly onto $a b$ plane showing ef $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions ..... 108
2.4 Packing diagram for 2a showing weak $\pi \cdots \pi$ interactions ..... 109

## LIST OF FIGURES (Continued)

Figures Page
2.5 Thermal ellipsoid plot of a fragment of $\mathbf{2 b}$ ..... 111
2.6 1-D chain propagating along the $a$ axis in $\mathbf{2 b}$ ..... 112
2.7 The shortest contacts in 2b ..... 113
2.8 Packing in $\mathbf{2 b}$ along the $a$ axis showing the $\pi-\pi$ stacking between pyrimidine rings ..... 114
2.9 Perspective view of $\mathbf{2 b}$ along the $a$ axis ..... 115
2.10 Thermal ellipsoid plot of a fragment of 2c ..... 116
2.11 1-D chain propagating along the $c$ axis in 2c ..... 118
2.12 Packing diagram in 2c view along the $b$ axis showing the $\pi-\pi$ interactions ..... 118
2.13 Thermal ellipsoid plot of a fragment of 2d ..... 120
2.14 View crystal structures of $\mathbf{2 d}$ along the (a) $c$ and (b) $b$ axis ..... 122
2.15 Thermal ellipsoid plot of a fragment of $\mathbf{2 e}$ ..... 123
2.16 Unit cell packing diagram showing different orientation of 1-D chains in $\mathbf{2 e}$ ..... 125
2.17 View of $\pi \cdots \pi$ interactions in $\mathbf{2 e}$ ..... 126
2.18 View of anion $\cdots \pi$ interactions in $\mathbf{2 e}$ ..... 126
2.19 The structure of $\mathbf{2 f}$ ..... 130
2.20 (a) Wires-sticks and (b) space-filling representations
showing 2-D sheet in $\mathbf{2 f}$ linked by $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds ..... 131
3.1 Thermal ellipsoid plot of a fragment in 3a ..... 158

## LIST OF FIGURES (Continued)

## Figures

Page
3.2 A projection along the $a$ axis showing the 2-D corrugated sheets in $\mathbf{3 a}$160
3.3 Schematic view of the 2-D corrugated sheets of the bimetallic skeleton in 3a ..... 161
3.4 Packing diagram of 3a viewed along along the $c$ axis the $c$ axis showing $\pi \cdots \pi$ stacking between the 2-D corrugated sheets ..... 162
3.5 Ball and strict representation of the asymmetric unit in $\mathbf{3 b}$ ..... 164
3.6 Views of (a) side, (b) top views of 1-D tubular structure, (c) $\mathrm{Fe}_{3} \mathrm{Mn}_{3}$ hexanuclear arrangement, and (d) schematic view of the tube topology in 3b ..... 166
3.7 Views of (a) packing of the three and (b) single 1-D tubes in 3b ..... 167
3.8 (a) Stick and (b) space filling representations representation of seven 1-D tubes in top view of $\mathbf{3 b}$ ..... 168
3.9 Ball and stick representation of the asymmetric unit in 3c ..... 170
3.10 Views of 1-D tube like structure in 3c ..... 173
3.11 View of 1-D chain linked via $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds in 3c along the $a$ axis ..... 174
3.12 2-D sheet generated through a combination of self- complementary $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds and $\pi-\pi$ stacking ..... 175
3.13 Ball and stick representation showing the atom connectivity and coordination environment in 3d ..... 178

## LIST OF FIGURES (Continued)

## Figures

Page
3.14 Thermal ellipsoid plot at
the $50 \%$ probability level of 3e containing
coordination environments of metals centre shown .................................... 179
3.15 View of the 1-D zigzag chains in 3e running parallel to the $b$ axis ..... 181
3.16 Stacking of four consecutive $\mathrm{Fe}-\mathrm{Ni}$ bimetallic chains of $3 \mathbf{e}$ along the $c$ axis ..... 182
3.17 Plot of magnetic moment in fields of $0.01,0.1$, and 1 T for $\mathbf{3 a}$ ..... 184
3.18 The DC magnetization isotherms ( $0-5 \mathrm{~T}$ ) for 3a ..... 186
3.19 Plot of magnetic moment in fields of $0.01,0.1$, and 1 T for $\mathbf{3 b}$ ..... 187
3.20 The DC magnetization isotherms ( $0-5 \mathrm{~T}$ ) for $\mathbf{3 b}$ ..... 188
3.21 Temperature dependence ( $4-35 \mathrm{~K}$ ) of FCM and ZFCM for $\mathbf{3 b}$ ..... 189
3.22 Plot of magnetic moment, per [CuFe] for $\mathbf{3 c} \mathbf{- 3 d}$, and per [ NiFe ] for $\mathbf{3 e}$ ..... 191
4.1 Perspective view of $\mathbf{4 a}$ with the atom-numbering scheme ..... 217
4.2 Packing diagram of 4a view along the $c$ axis ..... 218
4.3 Views of supramolecular interactions in 4a ..... 219
4.4 Crystal packing in 4a along the $c$ axis ..... 220
4.5 Histogram plot of distribution of $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts between two $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ fragments obtained from the CSD ..... 221
4.6 Part of the crystal structure of $\mathbf{4 a}$ ..... 222
4.7 Perspective view of $\mathbf{4 b}$ with the atom-numbering scheme ..... 223
4.8 The 2-D sheet in $\mathbf{4 b}$ ..... 225

## LIST OF FIGURES (Continued)

Figures Page
4.9 Perspective view of $\mathbf{4 c}$ with the atom-numbering scheme ..... 226
4.10 View of 1-D ladder like chain in 4c ..... 227
4.11 (a) Ball and stick and (b) space-filling representation showing two ladder chains in $\mathbf{4 c}$ viewed along the $b$ axis ..... 228
4.12 The 2-D sheet in $\mathbf{4 c}$ ..... 230
4.13 Crystal packing in 4c along the $a$ axis ..... 230
4.14 Perspective view of $\mathbf{4 d}$ with the atom numbering scheme ..... 231
4.15 The 2-D sheet with the $(6,3)$ topology in 4c ..... 232
4.16 Schematic view of the 3-D 4-connected network with $4^{2} .6^{3} .8$ topology for $\mathbf{4 d}$ ..... 233
4.17 (a) Wires/sticks and (b) space filling representations of single 3-D framework with 1-D channels in 4d ..... 234
4.18 (a) Ball and stick and (b) space-filling representations of the interpenetrating nets of $\mathbf{4 d}$ ..... 235
4.19 Views of a fragment of the alternating nets in $\mathbf{4 d}$ showing
(a) the $\mathrm{Ag} \cdots \mathrm{Ag}$ argentophilic and (b) $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ interactions ..... 236
4.20 Plot of magnetic moment in field of 1 T for $\mathbf{4 b}$ ..... 237
5.1 View of $\mathbf{5 a}$ with the atom numbering scheme ..... 254
5.2 The 2-D sheet motif in 5a ..... 256
5.3 Projection of the 3-D network structure of 5a ..... 257
5.4 The detailed view of the hydrogen bonds in the 5a ..... 258
5.5 Perspective view of part of the structure in $\mathbf{5 b}$ ..... 260

## LIST OF FIGURES (Continued)

Figures Page
5.6 View of 1-D of a square shaped $[\mathrm{Ni}-\mathrm{Ni}]$ core in $\mathbf{5 b}$ ..... 261
5.7 Perspective view of column structure in $\mathbf{5 b}$ ..... 262
5.8 Perspective view of the cell packing in $\mathbf{5 b}$ ..... 262
5.9 The detailed view of the hydrogen bonds in $\mathbf{5 b}$ ..... 263
5.10 Schematic views of the 3-D
4-connected network for (a) $\mathbf{5 a}$ and (b) 5b ..... 264
5.11 Temperature dependent magnetic behaviours of (a) $\mathbf{5 a}$ and (b) $\mathbf{5 b}$ ..... 266
5.12 ATR-FTIR spectra of $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}, \mathbf{5 a}$, and $\mathbf{5 b}$ ..... 268
5.13 TGA (red) and DTA (blue) profiles for 5a ..... 270
5.14 TGA (red) and DTA (blue) profiles for $\mathbf{5 b}$ ..... 271
6.1 View showing asymmetric unit with the atom numbering in $\mathbf{6 a}$ ..... 295
6.2 Comparison of $\mathrm{Fe}-\mathrm{N}$ bond lengths in $\mathbf{6 a}$ and $\mathbf{6 b}$ at 103 and 233 K ..... 297
6.3 Schematic representation for comparison of distorted octahedral geometry around Fe (II) centres in (a) $\mathbf{6 a}$ and (b) $\mathbf{6 b}$ ..... 299
6.4 Views of AIBN ligands in (a) $\mathbf{6 a}$ and (b) $\mathbf{6 b}$ ..... 301
6.5 (a) Views of the 3-D net in the structure of $\mathbf{6 a}$ at 103 K .
(b) Schematic presentation of the $\alpha$-Po related net in 6a ..... 303
6.6 View showing the asymmetric unit with the atom numbering in $\mathbf{6 c}$ ..... 305
6.7 View of 2-D $(4,4)$ sheets in $\mathbf{6 c}$ along the $b$ axis ..... 306
6.8 View slightly offset from the $b$ axis showing the the 2-D layered structure in $\mathbf{6 c}$ ..... 307

## LIST OF ABBREVIATIONS

| $\AA$ | Angstrom |
| :---: | :---: |
| $\Delta J$ | anisotropic in $J$ |
| H | applied field |
| $N$ | Avogadro's number |
| $\theta$ | Bragg angle or scattering angle |
| $\mu_{\mathrm{B}}$ or B.M. | Bohr Magneton |
| $k$ | Boltzmann constant |
| Oe | centimeter-gram-second electromagnetic |
|  | unit of magnetic intensity |
| $C_{g}$ | centroids of ring |
| $\Delta \delta$ | change of difference in $\delta$ |
| $z$ | charge on an ionic species |
| $H_{\text {C }}$ | critical fields |
| $\Delta$ | (i) crystal field splitting parameter |
|  | (ii) spectra width |
| C | Curie constant |
| $T_{\text {C }}$ | Curie temperature |
| ${ }^{\circ} \mathrm{C}$ | degrees celsius |
| $\chi_{\text {dia }}$ | diamagnetic susceptibility |
| $\mu_{\text {eff }}$ | effective magnetic moment |
| $\rho$ | electron density |

## LIST OF ABBREVIATIONS

| $\chi_{\mathrm{g}}$ | gram molar susceptibility |
| :---: | :---: |
| -H $\cdots$ | hydrogen bond interaction |
| $\Gamma$ | half-width at half-height |
| d[ - ] | interatomic bond distance for normal bonded atoms |
| $\mathrm{d}[\cdots]$ | interatomic bond distance involving a noncovalent atom |
| $\angle[-]$ | interplanar dihedral angle |
| $\angle[--]$ | interatomic angle for normal bonded atoms |
| $\angle[-\cdots]$ | interatomic angle involving a noncovalent interaction |
| $\angle[---]$ | interatomic torsional angle |
| $\delta$ | isomer shift (IS) |
| $U[$ ] | isotropic atomic displacement parameter for the indicated atom |
| ... | noncovalent interaction or nonbonded interatomic separation |
| - | primarily covalent interaction or coordination interaction |
| $\mu$ | linear absorption coefficient |
| $\mu_{\text {o }}$ | magnetic constant, permeability of a vacuum |
| B | magnetic flux density |
| $\chi$ | magnetic susceptibility |
| Mg | Milligram |
| mm | millimeter |
| M | molar magnetization |
| $\chi_{\mathrm{M}}$ | molar susceptibility |
| nm | nanometer |

## LIST OF ABBREVIATIONS

| $T_{\mathrm{N}}$ | Néel temperature |
| :---: | :---: |
| Z | number of formula units in the unit cell or |
|  | atomic number of an atom |
| $n$ | number of unpaired spins |
| $\Delta E_{Q}$ | quadrupole splitting (QS) |
| $J$ | rotation quantum number |
| Ms | saturation magnetization |
| $H^{2}$ | second order field effects (Zeeman) |
| $\lambda$ | spin orbit coupling constant |
| T | Teslar |
| $T$ | temperature |
| $S$ | total spin |
| $\bar{\lambda}$ | wavelength of x-radiation |
| $v$ | wavenumbers |
| wt \% | weight percent |
| $\Theta$ | Weiss constant |
| $\alpha, \beta, \gamma$ | unit cell angles |
| $a, b, c$ | unit cell dimensions |
| 1-D | one-dimensional |
| 1,10-phen | 1,10-phenathroline |
| 2-D | two-dimensional |
| 2,2'-bipy | 2,2'-bipyridine |

## LIST OF ABBREVIATIONS

| 3-D | three-dimensional |
| :--- | :--- |
| 4AE | fourfold aryl embrace |
| 4,4'-bipy | 4,4'-bipyridine |
| AC | alternating current |
| ACCN | $1,1^{\prime}$-azobiscyclohexanecarbonitrile |
| AIBN | 2,2'-azobisisobutyronitrile |
| ampy | aminomethylpyridine |
| Anal | Analysis |
| ANU | The Australian National University |
| ATR-FTIR | Attenuated Total Reflection Fourier Transform Infrared |
| azpy | trans-4,4-azopyridine |
| B.C. | Before Christ |
| bmtz | 3,6-bis(2'-pyrimidyl)-1,2,4,5-tetrazine |
| bppn | bis(2'-pyridyl)-1,2-pyridazine |
| bpm | bis(1-pyrazolyl)methane |
| bptz | 3,6 -bis(2-pyridyl)-1,2,4,5-tetrazine |
| bpym | $2,2^{\prime}$-bipyrimidine |
| btr | tris(4,4'-bis-1,2,4-triazole) |
| btzb | 1,4 -bis(tetrazol-1-yl)butane-N4,N4' |
| btzpol | 1,3 -bis(tetrazol-1-yl)-2-propanol |
| calcd | calculated |
| cddt | 2-chloro-4,6-bis(dipyrid-2-ylamino)-1,3,5-triazine |
| Compact Disk Read Only Memory |  |

| pmd | pyrimidine |
| pn | 1,2-diaminopropane |
| PXRD | powder X-ray diffraction |
| py | pyridine |
| pyz | pyrazine |
| reme | rris(4-carboxylato-2,3,5,6-tetrachlorophenyl)methane |

## LIST OF ABBREVIATIONS

| SCMs | single chain magnets |
| :---: | :---: |
| SCO | spin-crossover |
| SEM | scanning electron microscope |
| SHELXL-97 | least squares structure refinement program |
| SHELXS-97 | least squares structure solution program |
| S.I. | International System of Units |
| SIR97 | direct methods structure solution software |
| SMMs | single-molecule magnets |
| SQUID | Superconducting Quantum Interference Devices |
| SUT | Suranaree University of Technology |
| tacn | 1,4,7-triazacyclononane |
| $\mathrm{tcm}^{-}$ | tricyanomethanide |
| tet | tetrahedron |
| TGA | Thermogravimetric Analysis |
| TIP | temperature independent susceptibility |
| tn | 1,3-diaminopropane |
| tpa | tris(2-pyridylmethyl)amine |
| tptz | 2,4,6-tri(2-pyridyl)-s-triazine |
| tren | tris(2-aminoethyl)amine |
| trine | triethylenetetraamine |
| $w R_{2}$ | weighted crystallographic discrepancy index |
| ZFCM | zero-field- cooled magnetization |
| ZFS | zero-field splitting |

## CHAPTER I

## A GENERAL INTRODUCTION

In the last decade, there has been much interest in nanotechnology because of its broad applications across many fields of science and engineering. Creation of localized scientific community networks dedicated to identification, development, and commercialization of inventions from nanotechnology remains important to the overall success of any region attempting to benefit from the tremendous economic potential of nanotechnology. Porous materials have attracted the attention of chemists, physicists, and materials scientists due to their interest in the creation of nanometer sized spaces and the novel phenomena that occur in them.

Hybrid organic-inorganic materials are an important subclass of porous materials that usually possess open-framework structures, and are of great contemporary interest in materials science and chemical research, Figure 1.1. They are currently one of the hot topics in the development of nanoscience and nanotechnology (Rao et al., 2007). These hybrid materials are very attractive because properties of organic materials (eg. optical, electrical, and magnetic functionality, porosity, and hydrophobicity) are combined with those of inorganic materials (eg. rigidity, high surface area, thermal stability, and mechanical stability). The hybrid concept has made accessible an immense new area of materials science with extraordinary implications for the development of multifunctional advance materials such as optical materials, magnetic materials, electrical materials, solid electrolytes,
chemical sensors, catalysts, separation membranes, and gas storage materials (Rao et al., 2004; 2007).

Figure 1.1 Occurrence of the term "hybrids organic-inorganic" in titles of papers published between 1995 and 2007 (SciFinder Scholar search: July, 2008).

A precise definition of hybrid organic-inorganic framework materials has been given by Cheetham et al. (2004) as "compounds that contain both inorganic and organic moieties as integral parts of a network with infinite bonding connectivity in at least 1-D". Such materials can be conveniently divided into two categories, firstly, called "coordination polymers", which are defined as extended arrays composed of
metal atoms or clusters bridged by polyfunctional organic molecules (Batten, 2001; 2004), and secondly, "hybrid metal oxides", which contain infinite metal-oxygen -metal (M-O-M) arrays as a part of their structures (Cheetham et al., 1998). For other materials, where the organic part is located within the pores and does not bond to the framework except through van der Waals, coulombic, or hydrogen bond interactions, the term "organically templated porous solids" is used.

### 1.1 Supramolecular Chemistry

Supramolecular chemistry has its roots in nature, and is one of the most popular and fastest growing areas of experimental science. It combines knowledge from chemistry, biology, and physics while utilizing the most modern research technology (Lehn, 1990; Steed and Atwood, 2000). One precise definition of supramolecular chemistry has been given by Jean-Marie Lehn, who received a Nobel Prize for his pioneering work on supramolecular chemistry in 1987, as "chemistry of the intermolecular bond, covering the structures and functions of the entities formed by association of two or more chemical species" (Lehn, 1988). An example of a supramolecular assembly reported by Lehn and co-workers is shown in Figure 1.2. More extended definitions, including the nature of the interactions have been recently offered; "the study of systems involving aggregates of molecules or ions held together by non-covalent interactions, such as electrostatic interactions, hydrogen bonding, dispersion interactions and solvophobic effects" (Steed et al., 2007).

More recently, using concepts in the area of supramolecular chemistry based on size and shape of materials, supramolecular chemistry can be split into two broad categories: (i) host-guest chemistry and (ii) self-assembly (Steed et al., 2007).

Figure 1.2 Self-assembly of the circular helicate $\left[\left(\mathrm{Fe}_{5} \mathrm{~L}_{5}\right) \mathrm{Cl}\right]^{9+}$ from five tris-bpy ligand strands L and five equivalents of $\mathrm{FeCl}_{2}$. Drawn from coordinates from CSD, after Hasenknopf et al., 1996.

### 1.1.1 Supramolecular Host-Guest Chemistry

The definition of host-guest is very broad. In supramolecular chemistry, according to the statement by Steed et al. (2007), the term of "host" is used when one molecule is significantly larger than another molecule, whereas the smaller molecule is the "guest" and the large host molecules are capable of enclosing the smaller guest molecules via noncovalent interactions. A representative example of supramolecular solid state host-guest chemistry is the guest-dependent spinc crossover (SCO) in the nanoporous molecular framework material of $\left[\mathrm{Fe}_{2}(\text { azpy })_{4}(\mathrm{NCS})_{4}\right] \cdot$ (guest), azpy $=$
trans-4,4-azopyridine, Figure 1.3. In this structure, pore size and thermal behavior of the material depend on the presence of small molecules (low molecular weight alcohols) in the lattice. Such complexes are referred to as host-guest complexes, where the lattice provides the "host" and the small, sorbed molecules are the "guests". The most striking feature of the material is the change in the magnetic and optical properties. SCO behavior was successfully controlled by both guest removal and sorption. In the presence of guest molecules, $50 \%$ of the high-spin (HS) Fe(II) atoms became low-spin (LS) below 50 K . However, in the absence of guest, no SCO occurred (Halder et al., 2002). More recent reviews of supramolecular solid state host-guest chemistry are available (Beatty, 2003; Wan et al., 2006; Dalgarno et al., 2008).

### 1.1.2 Self-Assembly

When there is no significant difference in size, and no species is acting as a host for another, the joining of two or more species is termed "self-assembly". Steed et al. (2007) has given the generic definition broadened over time to incorporate many aspects of biochemistry and nanotechnology as "the spontaneous and reversible association of molecular species to form larger, more complex supramolecular entities according to the intrinsic information contained in the components". This process is usually spontaneous but may be influenced by solvation or templation effects or in the case of solids by the nucleation and crystallisation processes. Many examples of self-assembly process are metal-ligand complexes. Fujita and co-workers has reacted pyridyl or pyrimidyl functionalised planar or near planar ligands with cisprotected Pd in order to synthesize a substantial series of metal-organic cages (Umemoto et al., 2001; Chand et al., 2002; Tominaga et al., 2004; Sato et al., 2006;

Figure 1.3 Guest inclusion/removal in $\left[\mathrm{Fe}_{2}(\text { azpy })_{4}(\mathrm{NCS})_{4}\right] \cdot$ (guest). Drawn from coordinates from CSD, after Halder et al., 2002.

Suzuki et al., 2007; Yoshizawa et al., 2007). An impressive example from their works uses V-shaped ligands of 1,3-bis(4-pyridyl)-5-benzyl ester ethyl ester which bind with naked palladium centers to afford finite spherical coordination cages that have a diameter of $c a .3 \mathrm{~nm}$, Figure 1.4a (Tominaga et al., 2004). In related work, Stang and co-workers have used $\operatorname{Pt}\left(\mathrm{PMe}_{3}\right)_{2}(\mathrm{OTf})_{2}$ as a V -shaped metallic building unit reacted with triangular shaped 1,3,5-tris(4-pyridyl-trans-ethenyl)benzene in a 3:2 ratio to build discrete supramolecular architectures of $c a .1-1.5 \mathrm{~nm}$ of size, Figure 1.4 b (Schweiger et al., 2005). Similarly, Dalcanale and co-workers synthesized nano cages formed by picolyl-bridged cavitands, preorga-nized for cage self-assembly via coordination to Pt metal precursors, and its structure was determined using synchrotron radiation at low temperature, Figure 1.4c (Pinalli et al., 2004).

Self-assembled metallo-supramolecular capsules are of contemporary great interest research due to their potential application in the fields of sensors and catalysis (Dalgaro et al., 2008). Strategies developed in their construction have mainly relied on self-assembly or arranging molecules through metal-ligand interactions or the use of hydrogen bonds (Prins et al., 2001; Steed 2001; Cho et al., 2002; McKinlay et al., 2005). Atwood and co-workers reported interesting nano capsules composed of a large neutral discrete pseudo-spherical coordination complexes assembled from 6 pyrogallol[4]arene ligands and $24 \mathrm{Cu}(\mathrm{II})$ metal ions, Figure 1.5. Amazingly, this coordination capsule is structurally analogous to its hydrogen bonded counterpart. The result shows the robust ability of pyrogallol[4]arene molecules to self-assemble into large hexameric cage structures from either hydrogen-bonding or metal-ligand coordination processes (McKinlay et al., 2005).

Figure 1.4 Self-assembly of nanosize coordination cages. Drawn from coordinates from CSD, after (a) Tominaga et al., 2004, (b) Schweiger et al., 2005, and (c) Pinalli et al., 2004.

Figure 1.5 (a) Ball-wires-sticks and (b) space-filling representations of the hexameric coordination capsule showing the metal-directed self-assembly of part of 6 pyrogallol[4]arenes and $24 \mathrm{Cu}(\mathrm{II})$ ions. Drawn from coordinates from CSD, after McKinlay et al., 2005.

Another example is a molecular tubular assembly which was also discovered by Atwood and co-workers (Orr et al., 1999). In this structure, the authors successfully react amphiphilic polyhedron-shaped $p$-sulfonatocalix[4]arene pyridine $N$-oxide ligands with lanthanide ions to afford spherical and helical tubular structures. The tube is $c a .1 .5 \mathrm{~nm}$ in diameter. These tubular assemblies are arranged in a hexagonal array as shown in Figure 1.6. A related system has been obtained in the present work and described in Chapter III.

Weak, noncovalent interactions between molecules control many biological functions (Jeffrey and Saenger, 1991; Desiraju and Steiner, 1999). In chemistry,
noncovalent interactions are now exploited for the synthesis in solution of large supramolecular aggregates. The aim of these syntheses is not only the creation of a particular structure, but also the introduction of specific chemical functions in these supramolecules.

Figure 1.6 View of the hexagonal packing of tubules composed of $p$-sulfonatocalix-
[4] arene with intercalated pyridine $N$-oxide. Drawn from coordinates from CSD, after Orr et al., 1999.

### 1.1.3 Supramolecular Interactions

The phrase "supramolecular interactions" throughout this thesis is intended to should be assumed to mean noncovalent interactions, unless specified otherwise. Covalent bonds are a common type of bonding formed as a result of the sharing of one or more pairs of bonding electrons, i.e. formed by overlapping of partially
occupied orbital of interacting atoms. In contrast, the formation of noncovalent interactions does not involve the sharing of pairs of electrons, because the attraction comes from the electrical properties of the building blocks (Muller-Dethlefs and Hobza, 2000). Covalent bonds are generally shorter than $2 \AA$, while noncovalent interactions function within a range of several angstroms. Covalent interactions range between ca. $150 \mathrm{~kJ} \mathrm{~mol}^{-1}$ to $450 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for single bonds, and are considerably stronger than noncovalent interactions, which can range from $2 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for dispersion interactions to $300 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for ion-ion interactions (Steed et al., 2007). Noncovalent interactions lead to the formation of a molecular cluster while covalent interactions lead to the formation of a classical molecule. The noncovalent interactions involved in supramolecular entities may be a combination of several types of interaction as follows.

Ion-ion interactions (200-300 $\mathrm{kJ} \mathrm{mol}^{-1}$ ) are attractive interactions between a positive ion and a negative ion or repulsion between two ions of the same charge. This supramolecular ion-ion interaction is non-directional in nature which means that the interaction can occur in any orientation, and is comparable with covalent interactions. An example of a supramolecular ion-ion interaction can be seen in the crystal structure of sodium chloride (Klewe and Pedersen, 1974).

Ion-dipole interactions $\left(40-210 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ are the electrostatic attractions between ions and dipoles (the separation of charge in a bond or a molecule with a positively charged end and a negatively charged end) of molecules. An example of a ion-dipole interaction is the alkali metal Cs cation interacting with polar [18]crown-6, Figure 1.7, in the structure of $\mathrm{Cs}_{2}([18] \text { crown }-6)_{3}\left[\mathrm{Ni}(\mathrm{dmit})_{2}\right]_{2}$, dmit $=2$-thioxo-1,3-dithiole-4,5-dithiolate (Akutagawa et al., 2005). Other examples of this interaction are
a series of the alkali metals (i.e. $\mathrm{Li}, \mathrm{Na}, \mathrm{K}, \mathrm{Rb}$, and Cs ) with marcrocyclic crown ether molecules reviewed by Steed (2001).

(a)

(b)

Figure 1.7 (a) Ball-stick and (b) space filling model showing ion-dipole interactions in the cesium complex of [18]crown-6. Drawn from coordinates from CSD, after Akutagawa et al., 2005.

Dipole-dipole interactions ( $5-50 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ) are intermolecular or intramolecular interactions between molecules or groups of atoms having permanent electric dipole moments. The strength of the interaction depends on the distance, strength of the dipoles, and relative orientation of the dipoles. The term also applies to intramolecular interactions between bonds having permanent dipole moments. Allen and co-workers reported the investigation of geometries and attractive energies of dipole-dipole carbonyl-carbonyl interactions by using crystallographic data and $a b$ initio molecular-orbital calculations (Allen et al., 1998). Three common interaction motifs are observed in crystal structures: (i) a slightly sheared antiparallel motif interactions, $22.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$, (ii) a perpendicular motif, $20 \mathrm{~kJ} \mathrm{~mol}^{-1}$, and (iii) a highly sheared parallel motif, $7.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$. These energies are comparable to those of
medium-strength hydrogen bonds. An example of these interactions is antiparallel carbonyl-carbonyl interaction between the positive polarity carbon atom and the negative polarity oxygen atom of adjacent carbonyl groups in pyridine-3,5dicarboxylic acid (Cowan et al., 2005).

Hydrogen bond interactions ( $4-120 \mathrm{~kJ} \mathrm{~mol}{ }^{-1}$ ) are bonding interactions between acidic hydrogen atoms and negatively charged or negatively polarized atoms with (or without) lone-pairs as depicted in Figure 1.8a. They are described by the formula $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ (where D represents the donor atom that is bonded to the acidic hydrogen atom, and A represents the acceptor atom to which the acidic hydrogen atom is bonded). Hydrogen bonds are widely exploited in molecular crystal engineering (Desiraju, 1996; 2002; 2003), have been used extensively in molecular recognition applications (Hosseini, 2003), and are especially important because they best combine both strength and directionality (Jeffrey, 1997; Scheiner, 1997; Braga and Grepioni, 2001).

The most commonly used criteria for identification of a strong hydrogen bond, are the interatomic distances $\mathrm{H} \cdots \mathrm{A}$ and $\mathrm{D} \cdots \mathrm{A}$, and the angle $(\theta)$, illustrated in Figure 1.8b. If the distance between the hydrogen and acceptor atoms is significantly shorter than the sum of van der Waals radii, and if $\theta$ is close to $180^{\circ}$, a hydrogen bond is usually present. Several studies have shown the angular dependence of $\theta$ to be related to the strength of the hydrogen bond (Bernstein et al., 1994). Stronger hydrogen bonds tend to show a shorter $\mathrm{H} \cdots \mathrm{A}$ distance, correlated with an elongated $\mathrm{D}-\mathrm{H}$ bond and a $\theta$ between $170-180^{\circ}$. In cases where the acceptor is a carbonyl $(\mathrm{C}=\mathrm{O})$, the $\phi$ angle is most frequently between $110^{\circ}$ and $130^{\circ}$, corresponding to the regions of the lone electron pairs (Braga et al., 1994). Irrespective of the criteria listed
above, it has become widely accepted that there is a hydrogen bond interaction whenever the $\mathrm{H} \cdots \mathrm{A}$ and/or the $\mathrm{D} \cdots \mathrm{A}$ distances are less than the sum of the van der Waals radii. Accordingly, a list of van der Waals radii, such as that in Table 1.1 for some common atoms, with comparison between Pauling (1945), Bondi (1964), and Rowland and Taylor (1996) radii is an essential tool for observing hydrogen bonds.

(a)

(b)

Figure 1.8 Hydrogen bond geometry and partial charges. (a) Donor and acceptor atoms and (b) angular dependence in a primary hydrogen bonds interactions.

Table 1.1 The van der Waals radii (in $\AA$ ) used for observing hydrogen bonds.

Linear

Figure 1.9 Structures of common hydrogen bond types. Redrawn after Lutz, 2003.

The structure and strength of hydrogen bonds in inorganic solids has recently been examined by Lutz (2003). He remarked that they depend on several factors, including the various $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ motifs possible, the inherent hydrogen bond donor strength of the acid hydrogen atom, the inherent acceptor capability of the respective acceptor groups, collective phenomena (cooperative, competitive, and synergetic effects), and structural features, such as the number of acceptors eg. two-center, threecenter (bifurcated), etc. hydrogen bonds, and the hydrogen bond angles $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ (linear or bent) and $\mathrm{H} \cdots \mathrm{A}-\mathrm{R}$. As already mentioned, the nature and strength of hydrogen bonds strongly depends on both the hydrogen-bond donors and acceptors involved and the structural arrangement of the hydrogen bonds. Therefore, the
structural arrangement including geometry, coordination, and configuration is essential for understanding hydrogen bonding. Figure 1.9 illustrates the structures of several common hydrogen bond types. A simple example of hydrogen bonds exhibiting directional properties are the 2-D honeycomb networks based upon $\left[\mathrm{Ni}(\mathrm{Hbim})_{3}\right]^{-}$building blocks (Hbim = biimidazolium) linked by $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds in an $R_{2}^{2}(10)$ synthon (Tadokoro et al., 1999), as shown in Figure 1.10.

Figure 1.10 View of honeycomb hydrogen bonds sheets in $\left[\mathrm{Ni}(\mathrm{Hbim})_{3}\right]^{-}$building block. Drawn from coordinates from CSD, after Tadokoro et al., 1999.

(a)

(b)

Figure 1.11 Schematic representation of (a) attractive and (b) repulsion of secondary hydrogen bonds interactions. Redrawn after Steed et al., 2007.

The above example contains "primary hydrogen bond interactions" in which the hydrogen bonds are formed by a directional interaction between the donor and the acceptor groups. However, there are also "secondary hydrogen bond interactions" possible between neighboring groups, as illustrated in Figure 1.11. In these interactions stabilization arises from electrostatic attractions between positively and negatively polarized atoms in adjacent hydrogen bonds. Destabilization is likewise possible as a result of electrostatic repulsion between two positively or negatively polarized atoms. These hydrogen bonds have structural role in proteins and other biomolecules such as in the double helix of DNA (Bikadi et al., 2007). Mascal and co-workers (1996) have synthesized a DNA-base hybrid designed to function exclusively as the corner piece of a hexagon. The combination of the A-A-D sequence of cytosine and the complementary $\mathrm{D}-\mathrm{D}-\mathrm{A}$ sequence of guanine at an angle of $120^{\circ}$ to each other in pyrido[4,3-dpyrimidine], leads to the assembly of independent hexagonal aggregates in the solid state, Figure 1.12. This is a beautiful example of the communication of programmed, hydrogen bonding information.

The importance of weak hydrogen bonds has been established, and is recognized to be of importance in crystal engineering (Desiraju, 2007), as well as found to play important roles in the physical, chemical, and biological properties of a variety of substances (Desiraju and Steiner, 1999; Panigrahi and Desiraju, 2007). The $\mathrm{C}-\mathrm{H} \cdots \pi$ interaction is a weak hydrogen-bond occurring between soft acids and soft bases (Nishio et al., 1998). Examples of this interaction can be found in when $\mathrm{C}-\mathrm{H}$ bonds point directly towards the $\pi$-cloud of the benzene rings or $\mathrm{C} \equiv \mathrm{C}$ groups. Many examples of these interactions are available in reviews articles (Andrews et al., 1999; Lewiński et al., 2005).

(a)

(b)

Figure 1.12 (a) Ball-stick and (b) space filling representations of the enforced selfassembly of molecules of pyrido[4,3-dpyrimidine] into a hexamer. Drawn from coordinates from CSD, after Mascal et al., 1996.

The geometry of a hydrogen bond and the type of donor and acceptor groups determine the strength, length, and nature of the interactions. From these criteria, hydrogen bonds have been classified into three different types: (i) weak or doublewell hydrogen bonds, (ii) moderate or low barrier hydrogen bonds, and (iii) very strong or single-well hydrogen bonds (Prins et al., 2001). Classification and properties of hydrogen bonds adapted from Table 1 in The Weak Hydrogen Bond in Structural Chemistry and Biology by Desiraju and Steiner (1999) and Table 1.2 in Core Concepts in Supramolecular Chemistry and Nanochemistry by Steed, Turner, and Wallace (2007), are listed in Table 1.2.

Table 1.2 Classification and properties of hydrogen bonds.

| Interaction/property | Strong | Moderate | Weak |
| :--- | :--- | :--- | :--- |
| D-H $\cdots \mathrm{A}$ | Mainly covalent | Mainly electrostatic | Electrostatic |
| Bond energy $\left(\mathrm{kJ} \mathrm{mol}^{-1}\right)$ | $60-120$ | $16-60$ | $<12$ |
| Bond length $(\AA)$ | $\mathrm{D}-\mathrm{H} \approx \mathrm{H} \cdots \mathrm{A}$ | $\mathrm{D}-\mathrm{H}<\mathrm{H} \cdots \mathrm{A}$ | $\mathrm{D}-\mathrm{H} \ll \mathrm{H} \cdots \mathrm{A}$ |
| Lightening of $\mathrm{D}-\mathrm{H}(\AA)$ | $0.05-0.2$ | $0.01-0.05$ | $\leq 0.01$ |
| $\mathrm{H} \cdots \mathrm{A}(\AA)$ | $1.2-1.5$ | $1.5-2.2$ | $2.2-3.2$ |
| $\mathrm{D} \cdots \mathrm{A}(\AA)$ | $2.2-2.5$ | $2.5-3.2$ | $3.2-4.0$ |
| Bonds shorter than $\mathrm{H} \cdots \mathrm{A}$ <br> vdW separation $(\%)$ | 100 | Almost 100 | $30-80$ |
| $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ angle $\left({ }^{\circ}\right)$ | $175-180$ | $130-180$ | $90-150$ |
| Effect on crystal packing | Strong | Distinctive | Variable |
| Utilized in crystal <br> engineering | Unknown | Useful | Partly useful |
| Covalency | Pronounced | Weak | Vanishing |
| Electrostatic contribution | Significant | Dominant | Moderate |
| Examples | $[\mathrm{F} \cdots \mathrm{H} \cdots \mathrm{F}]^{-}$ | Acids | $\mathrm{C}-\mathrm{H} \cdots \mathrm{A}$ |
|  | $[\mathrm{F} \cdots \mathrm{H} \cdots \mathrm{N}]^{+}$ | Alcohols | $\mathrm{D}-\mathrm{H} \cdots \pi$ |
|  | $[\mathrm{F}-\mathrm{OH} \cdots \mathrm{O}=\mathrm{P}]$ | DNA/RNA |  |

Cation $-\boldsymbol{\pi}$ interactions ( $4-120 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ) are a noncovalent molecular interaction between the face of an electron-rich $\pi$ system, a quadrupole $e g$. benzene, ethylene, with an adjacent cation, a monopole eg. $\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}$(Mecozzi et al., 1996; Ma and Dougherty, 1997; Gokel et al., 2002), Figure 1.13. Cation $-\pi$ interaction energies are of the same order of magnitude of hydrogen bonds, and play an important role in molecular recognition (Dougherty, 1996). Numerous examples of cation $-\pi$ interactions in many organic and biochemical systems have been recently reported (Meyer et al., 2003).

Figure 1.13 Cation $-\pi$ interactions between benzene and a potassium cation.

Anion- $\boldsymbol{\pi}$ interactions are binding interactions between an electron-rich molecule and a $\pi$-acidic heteroaromatic ring (Quiñonero et al., 2002; Mooibroek et al., 2008). Such interactions are opposite to cation $-\pi$ interaction and significantly fewer examples of anion $-\pi$ interactions are known to date. However examples are increasingly reported in the recent literature of both experimental and theoretical investigations (Hoog et al., 2004; Mascal et al., 2007; Quiñonero et al., 2007; Zhou et al., 2007). The anion $-\pi$ effect is advantageously exploited in chemical sensors for specific anions (Francis et al., 2004). An illustrative example of this category has
been recently reported by Dunbar and co-workers. As shown in Figure 1.14, this structure displays $\left[\mathrm{SbF}_{6}\right]^{-}$anions encapsulated inside cavities formed by five 1,2,4,5tetrazine rings of 3,6-bis(2-pyridyl)-1,2,4,5-tetrazine (bptz) ligands. The [ $\left.\mathrm{SbF}_{6}\right]^{-}$ centroid distances are between 3.275 and $3.517 \AA$, which are indicative of strong anion $-\pi$ interactions (Campos-Fernandez et al., 2005). In a subsequent recent paper, Dunbar and co-workers have also used same ligand (bptz) and a related one, 3,6-bis(2'-pyridyl)-1,2-pyridazine (bppn) with the AgX salts $\left(\mathrm{X}^{-}=\left[\mathrm{BF}_{4}\right]^{-}\right.$, $\left[\mathrm{AsF}_{6}\right]^{-}$, $\left[\mathrm{PF}_{6}\right]^{-}$, and $\left[\mathrm{SbF}_{6}\right]^{-}$) to further explore of anion $-\pi$ interactions (Schottel et al., 2006). From the systems studied, the authors concluded that anion $-\pi$ interactions play an important role in the outcome of self-assembly reactions.

Figure 1.14 (a) Ball-stick and (b) space-filling representations, showing anion $-\pi$ interactions in $\left[\left\{\mathrm{Ni}_{5}(\mathrm{bptz})_{5} \subset\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{10}\right\} \mathrm{SbF}_{6}\right]\left(\mathrm{SbF}_{6}\right)_{9}$. Drawn from coordinates from CSD, after Campos-Fernandez et al., 2005.
$\boldsymbol{\pi}-\boldsymbol{\pi}$ interactions $\left(0-50 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ are weak electrostatic interactions that occur between aromatic moieties which can interact in different physical arrangements: face-to-face stacked arrangement (offset, slipped, or parallel displaced), and edge-toface or point-to-face, T-shaped conformations. These orientations come from $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions between positively charged hydrogen atoms (the $\mathrm{C}-\mathrm{H}$ bond generally having a small dipole moment) and a negatively charged $\pi$-cloud of the aromatic system. The perfect facial alignment of an eclipsed face-to-face orientation is unlikely because all the electrostatic interactions would be repulsive between the two negatively charged $\pi$-systems of the aromatic rings and between the positive ends of the C-H dipoles (Hunter and Sanders, 1990). The distance between the aromatic faces in a $\pi-\pi$ interaction is $c a .3 .3-3.8 \AA$ (Janiak, 2000). Types of aromatic-aromatic interactions are illustrated in Figure 1.15.

Figure 1.15 Schematic representations of aromatic-aromatic interactions.

A representative example is provided in the stacking of $1,3,5-\operatorname{tris}($ phenethynyl)benzene and 1,3,5-tris(perfluorophenethynyl)benzene in the solid state as shown in Figure 1.16. While the form slipped stacks with their terminal aryl rings twisted with respect to the plane of the central ring when crystallized separately, the 1:1 heterocomplex is essentially planar with markedly less slippage. These results provide excellent evidence for the structural control attainable when using the phenylperfluorophenyl synthon (Ponzini et al., 2000).

Metallophilic interactions, in this thesis, refer to (i) argentophilic $\left(\mathrm{Ag}^{\mathrm{I}} \cdots \mathrm{Ag}^{\mathrm{I}}\right)$, (ii) aurophilic $\left(\mathrm{Au}^{\mathrm{I}} \cdots \mathrm{Au}^{\mathrm{I}}\right)$, and (iii) cuprophilic $\left(\mathrm{Cu}^{\mathrm{I}} \cdots \mathrm{Cu}^{\mathrm{I}}\right)$ interactions. These interactions are useful tools for constructing supramolecular structures in the solid state (Fu et al., 2004; Mohr et al., 2004; Chu et al., 2005). The strengths of the argentophilic interactions are within the range of typical hydrogen bonds. Compared with aurophilic interactions ( $25-50 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ), argentophilic interactions are weaker but stronger than the related cuprophilic interactions (up to $16 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). Theoretical studies on dimeric models of linear two-coordinate complexes indicate that metallophilicity decreases as $\mathrm{Au}^{\mathrm{I}}>\mathrm{Ag}^{\mathrm{I}}>\mathrm{Cu}^{\mathrm{I}}$ (Magnko et al., 2002). Representative examples of argentophilic interactions can be found in a recent review by Young and Hanton (2008).
van der Waals interactions $\left(<5 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ are dispersion forces of relatively weak intermolecular interactions of two components, i.e. the London interactions and the exchange and repulsion interactions (Scheider, 2004). These interactions are nondirectional, and do not feature highly in supramolecular design but they are important in the formation of inclusion compounds (Steed et al., 2007).

Hydrophobic effects are the properties of those non-polar molecules that tend to form intermolecular aggregates in aqueous medium and analogous intramolecular interactions (Blokzijl and Engberts, 1993; Chandler, 2005). These interactions are of importance in many chemical and/or biological disciplines, including the chemistry of in vivo processes, enzyme-substrate interactions, the assembly of lipids in biomembranes, surfactant aggregation, and kinetic solvent effects in water-rich solutions (Pratt and Pohorille, 2002). Atwood and co-workers have described a simple model system that exemplifies proton transfer in a largely hydrophobic environment of calix[4]arene anion, $\mathrm{NH}_{4}$ cation and molecule of $\mathrm{NH}_{3}$. They show that the overriding preference for the ammonium cation is to associate directly with the deprotonated phenolic oxygen atom. This suggests that electrostatic interactions may play a key role in the stabilization of intermediate species in the initial stages of complex multistep proton-transfer processes such as those found in biological systems. This represents one example of such effects that occurred in supramolecular systems (Atwood et al., 2002).

Noncovalent interactions play an important role in chemistry and especially in biology. Due to the presence of a great number of cation $-\pi$ and $\pi-\pi$ interactions in biological systems, this effect is important and helps us understand some biological processes where the interplay between both interactions exist. Today, it also should be taken into account in the supramolecular chemistry of the crystal engineering field, the design of new solids with desired physical and chemical properties.

### 1.2. Crystal Engineering of Coordination Polymers

Single crystals are the most orderly manifestations of any state of matters, and are also the perfect example of a supramolecular assembly (Desiraju, 2003). The term "crystal engineering" was defined by G. R. Desiraju in 1989 as "the understanding of intermolecular interactions in the context of crystal packing and the utilization of such understanding in the design of new solids with desired physical and chemical properties" (Desiraju, 1989). Crystal engineering and design of solid-state architectures has become an area of recent increasing interest. (Batten and Robson, 1998; Moulton and Zaworotko, 2001; Hollingsworth, 2002; Yaghi et al., 2003; Kitagawa et al., 2004; Sieklucka et al., 2005; Khuong et al., 2006; Glaser, 2007).

Metal ligand compounds formed via coordination bonds that extend infinitely into 1-D to 3-D, are called "coordination polymers" (Batten, 2001; 2004). The crystal engineering of coordination polymers has received considerable attention in recent years since the first steps were taken with the seminal reports of Prof. Richard Robson, University of Melbourne, in eigthteen years ago (Robson and Hoskins, 1990). Presently, this field is an attractive area of research owing to the inherent stability of coordination bonds and also to the versatility of coordination modes of transition metal atoms. The predictable formation of coordination networks in order to design the entire crystal lattice have often been proposed or supported for the targeted synthesis of new materials (Ockwig et al., 2005; Champness, 2006).

### 1.2.1 Topology

One conceptual approach to building framework structures or topologies is based on the idea of a net (consisting of a collection of points or nodes). According to Wells (Wells, 1977), one notation for describing the topologies of coordination
networks in terms of the connectivity of the nodes has the general symbol $(n, p)$, where $n$ is the number of nodes in the smallest closed circuits in the net, and $p$ is the number of connections to neighboring nodes that radiate from any center or node. A more complete notation of Schläfli symbols is also described (Batten and Robson, 1998).

The topology of 3-D networks can be described in similar manners. Some 3-D structures have recently been reported to have the following topologies: boracite, $\mathrm{CdSO}_{4}, \mathrm{CaB}_{6}, \mathrm{NbO}$, perovskite, $\mathrm{Pt}_{3} \mathrm{O}_{4}, \mathrm{PtS}$, rutile, $\mathrm{SrSi}_{2}$, and tungsten bronze (Batten and Robson, 1998; Robson, 2000; Delgado-Friedrichs et al., 2005). The simplest infinite 3-D nets are depicted in Figure 1.17, and listed in Table 1.3.

### 1.2.2 Synthetic Strategies

The most significant goals in the field of crystal engineering are to tailor the chemical and/or physical properties of crystalline solids through crystal design at the molecular level (Seddon and Zaworotko, 1999; Braga and Crepioni, 2007). Two different design philosophies have been employed: (i) to use coordination bonds and (ii) to use highly directional hydrogen bonds and/or other weak electrostatic interactions as a very powerful and versatile strategy in material synthesis and/or controlling self assembly in supramolecular systems.

In theory, through the careful choice of metal ions, ligands and framework motifs can be rational synthesized to realize a certain desired framework. For example, if a tetrahedral node is employed, most commonly a tetrahedrally coordinating transition metal cation eg. $\mathrm{Cu}(\mathrm{I})$, then by far the most commonly observed structure is the diamond net (Hoskins and Robson, 1990). However, in fact, there are several factors such as metal to ligand ratios, metal coordination modes and
the presence of anions and guest molecules, which affects the formation of the expected polymeric or discrete supramolecular aggregates.

Figure 1.17 Some of the simplest infinite 3-D nets. (a) the 6 -connected in $\alpha$-Po net (or NaCl ), (b) the (3,6)-connected in rutile net and (c) the 4-connected in diamond net.

Table 1.3 Some selected examples of possible prototypes.

| Center A | Center B | Ratio | Prototype |
| :--- | :--- | :--- | :--- |
| Octahedral | - | - | $\alpha$-Po |
| Octahedral | Trigonal | $1: 2$ | Rutile $\left(\mathrm{TiO}_{2}\right), \alpha-\mathrm{PbO}_{2}$ |
| Tetrahedral | - | - | Diamond |
|  | - | - | Lonsdalite |
| Tetrahedral | Square Planar | $1: 1$ | PtS |
| Tetrahedral | Trigonal | $3: 4$ | $\mathrm{Ge}_{3} \mathrm{~N}_{4}$ |
| Square Planar | - | - | NbO |
| Square Planar | Trigonal | $3: 4$ | $\mathrm{Na}_{\mathbf{x}} \mathrm{Pt}_{3} \mathrm{O}_{4}$ |
| Trigonal | - | - | $\mathrm{ThSi}_{2}$ |

(Batten, 1995)

The preferred coordination number and geometry of the metal ion is one of important factors influencing the formation of a coordination network. Divalent and trivalent first-row transition metals have well known coordination preferences that often depend upon the identity of the ligand environment. For example, $\mathrm{Cr}^{\text {III }}$ is always octahedral, while $\mathrm{Mn}^{\mathrm{II}}$ is typically octahedrally coordinated by oxygen. $\mathrm{Co}^{\mathrm{II}}$ is more versatile and ranges from tetrahedral through pentacoordinated to octahedral, while $\mathrm{Ni}^{\mathrm{II}}$ is usually octahedral when surrounded by oxygen, but may be square planar in nitrogen environments. Isolated $\mathrm{Cu}^{\mathrm{II}}$ is relatively inflexible, and is constrained by its need to accommodate the Jahn-Teller distortion that is characteristic of $\mathrm{d}^{9}$ ions. $\mathrm{Zn}^{\text {II }}$, which has been widely used in studies on hybrid frameworks, is very versatile and behaves somewhat like $\mathrm{Co}^{\mathrm{II}}$.

For example, the rigid rod-like bidentate ligand of 4,4'-bipyridine (4,4'-bipy) reacts with different transition metal cations to yield very different final products depending on the metal centers. Yaghi and $\operatorname{Li}$ (1996) have shown how the $4,4^{\prime}$-bipy
ligand reacts with $\mathrm{AgNO}_{3}$ under mild hydrothermal condition to form extended 1-D chains, Figure 1.18a. Interestingly, adjacent chains are cross-linked in an almost perpendicular fashion by argentophilic ( $\mathrm{Ag} \cdots \mathrm{Ag}$ ) interactions leading to a 3-D open network. Recently, Pedireddi and co-workers have used the 4,4'-bipy ligand with $\mathrm{Cu}(\mathrm{I})$ centers in the presence of an ionic liquid of 1-ethyl-3-methylimidazolium tetrafluoroborate to synthesize a diamondoid network, Figure 1.18b, in which each copper has tetrahedral geometry (Pedireddi et al., 2006). In contrast, the product obtained from a hydrothermal reaction was found to be a polymer containing trigonal metal ions (MacGillivray et al., 1994). Subramanian and Zaworotko (1995) have found that the 2-D square grid networks formed by the 4,4'-bipy ligand with $\mathrm{Zn}(\mathrm{II})$ can be linked with $\left[\mathrm{SiF}_{6}\right]^{-}$counter ions in order to form a 3-D network with large channels, Figure 1.8c.

The role of the anions in the systems is clearly very important. Bu and coworkers have reported that the reactions of various $\mathrm{Cu}(\mathrm{II})$ salts with 2,5-bis(3-pyridyl)-1,3,4-oxadiazole in $\mathrm{CH}_{3} \mathrm{CN} / \mathrm{H}_{2} \mathrm{O}$ medium affords different complexes depending on the nature of the copper salt's counter ion (Du et al., 2003). Similarly, recently studies by Dong and co-workers (Dong et al., 2007) focused on temperature and anion-dependent synthesis of metal-organic frameworks. The authors have used a flexible ethylene glycol ether-bridging tetradentate ligand with bidirectional coordination donors of $\mathrm{AgX}\left(\mathrm{X}=\mathrm{BF}_{4}^{-}\right.$or $\left.\mathrm{SbF}_{6}\right)$ to synthesize four Ag coordination polymers. Recently, it has been demonstrated that a pentamer can also be templated by counter anion such as bromide or iodide (García et al., 2004).

The influence of different ancillary solvent ligands such as $\mathrm{CH}_{3} \mathrm{CN}, \mathrm{CH}_{3} \mathrm{OH}$, and $\mathrm{H}_{2} \mathrm{O}$ on the crystallization process is also one of factors affecting the formation of
the final network structure (Lee et al., 2004; Dong et al., 2006). For example, Wang and co-workers examined the solvent effects on the network structure formed. The authors used a flexible ligand dpap $2 \mathrm{H}_{2} \mathrm{O}$ (dpap $=2,6-\left(N, N^{\prime}\right.$-di(4-pyridyl)amino) pyridine) with 2 equivalents of $\mathrm{Cu}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in various solvents $\left(\mathrm{CH}_{3} \mathrm{CN}\right.$, $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CHCl}_{3}$ and $\mathrm{CH}_{3} \mathrm{OH}$ ), and obtained five coordination polymers in which the structures are influenced by the nature of the solvent (Wang et al., 2007).

Drawn from coordinates from CSD.

Many challenges in crystal engineering are still on the angstrom scale, but it may be extended to a controlled formation of nano-structured systems and even into the mesoscopic range, where optoelectronics and photonics open up new horizons for organic solids. Metal-organic frameworks (MOFs), a class of nanoporous coordination polymers, are of significant contemporary interest due to scientific interest in the creation of nanometer-sized spaces and their potential applications in molecular sieves, gas storage and heterogeneous catalysis (Yaghi et al., 2003; Kitagawa et al., 2004; Ferey et al., 2005). Early examples in the MOFs area can be found in the work of the groups of Yaghi (Li et al., 1999), Rossensinsky (Kepert et al., 1999) and Williams (Chui et al., 1999) in the late 1990s. Recently, several excellent comprehensive reviews on coordination networks have been reported (Kitagawa et al., 2004; 2007; Kawano and Fujita, 2007; Fromm et al., 2008; Suh et al., 2008).

### 1.3 Molecule-Based Magnetic Materials

The history of magnetism dates back to earlier than 600 B.C., but it is only in the twentieth century that scientists have begun to understand it, and develop technologies based on this understanding. Magnetic materials are essential for the operation of many of the devices used in modern industry such as recording devices. Depending on their ability to retain magnetization over long times, magnets are divided into two groups. "Soft" magnetic materials that lose their magnetic moment completely if the applied magnetic field is removed. "Hard" magnetic materials that keep their magnetic moment over many years without applying a magnetic field. Presently, the hard ferrites are the most used commercially available magnets, but
rare-earth-based magnets are developing rather quickly, both qualitatively and quantitatively.

All materials have an inherent magnetic character arising from the movements of their electrons. Magnetic properties arise from the interactions of unpaired electrons spins. These properties are traditionally found in transition metals, lanthanides, and their compounds due to the unpaired d- and f-electrons on the metal. In paramagnets, the net magnetic moment of the bulk material is zero due to the spin sites behaving independently and undergoing thermal motion. However, when a strong magnetic field is applied, the spins tend to align parallel to the field direction and it responds by producing a magnetic field, called the magnetization, $M$ (Kahn, 1993; Miller and Drillon, 2002). This magnetization is defined as the amount of magnetic moment per unit volume of the materials. The field that is applied to the material is called the applied field, $H$, and is the total field that would be present if the field were applied to a vacuum. Another important parameter is the magnetic flux density, $B$ (Kahn, 1993). When magnetic materials are placed in the field, the density of the lines of forces is decreased or increased for diamagnetic or paramagnetic materials, respectively. $B, H$ and $M$ are related by Eq. 1.1 in S.I. units.

$$
\begin{equation*}
B=\mu_{\mathrm{o}}(H+M) \tag{Eq. 1.1}
\end{equation*}
$$

where $\mu_{\mathrm{o}}$ is the magnetic constant.

However, the magnetization is usually discussed in terms of the degree of magnetization of a material in response to an applied magnetic field, and it is called the magnetic susceptibility, $\chi$ (Kahn, 1993; Miller and Drillon, 2002). Experimentally, in this work the $M$ value is obtained from the SQUID instrument output and it is then
converted into $\chi_{\mathrm{g}}$ (per gram), Eq. 1.2.

$$
\begin{align*}
\chi & =\frac{M}{H} \\
\chi_{\mathrm{g}} & =\frac{M}{H \times \operatorname{mass}(\mathrm{g})} \tag{Eq. 1.2}
\end{align*}
$$

In magnetochemistry, $\chi_{\mathrm{g}}$ is converted to the molar susceptibility, $\left(\chi_{\mathrm{M}}\right)$ and the ligand diamagnetic connections are made, Eq. 1.3. $\chi_{\text {dia }}$ is a negative term, and is obtained from Pascal's tables or measured directly.

$$
\begin{equation*}
\chi_{\mathrm{M}}=\chi_{\mathrm{g}} \mathrm{x}(\mathrm{MW})-\chi_{\mathrm{dia}} \tag{Eq. 1.3}
\end{equation*}
$$

Accordingly, the Curie-Weiss law indicates that the molecular susceptibility $\left(\chi_{\mathrm{M}}\right)$ of paramagnetic materials is inversely proportional to their Kelvin temperature (T), Eq. 1.4. This law is only valid under conditions of when $\chi$ is independent of the applied magnetic field $(H)$. This is the linear region of the $M$ versus $H$ plot given in 20 for paramagnets and ferromagnetic coupling at low $H$ values.

$$
\begin{equation*}
\chi_{M}=\frac{C}{T-\Theta} \tag{Eq. 1.4}
\end{equation*}
$$

where $C$ is the Curie constant, $\Theta$ is the Weiss constant.

The $\chi_{\mathrm{M}}$ values are often transformed into the effective magnetic moment, $\mu_{\text {eff }}$ (Kahn, 1993; Miller and Drillon, 2002). When $\Theta$ is zero in Eq. 1.4 (Curie law, $\chi_{\mathrm{M}}=$ $C / T$ ), this is independent of temperature as well as external field strength for paramagnetic materials which is a convenient measure of a material's magnetic
properties. The $\mu_{\text {eff }}$ is defined in Eq. 1.5, has the non S.I. unit of Bohr Magneton (B.M., $\mu_{\mathrm{B}}$ or $\beta$ ), and $\chi_{\mathrm{M}}$ is in $\mathrm{cm}^{3} \mathrm{~mol}^{-1}$.

$$
\begin{align*}
& \mu_{\mathrm{eff}}=\left(\frac{3 k}{N\left(\mu_{\mathrm{B}}\right)^{2}}\right)^{1 / 2} \sqrt{\chi_{\mathrm{M}} T} \\
& \mu_{\text {eff }}=2.828 \sqrt{\chi_{\mathrm{M}} T} \mu_{\mathrm{B}} \tag{Eq. 1.5}
\end{align*}
$$

where $k$ is Boltzmann constant, $N$ is Avogadro's number

It is common now to use $\chi_{\mathrm{M}} T$ (in $\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ ) at a particular $T$ instead of converting to $\mu_{\text {eff }}$.

For first row transition metal ions in the free ion state, i.e. isolated ions in a vacuum, all five 3d orbitals are degenerate. In octahedral complexes, a simple crystal field theory approach suggests that for these ions the d orbitals are no longer degenerate but are split such that two orbitals, the $d_{x^{2}-y^{2}}$ and the $d_{z^{2}}$ are at higher energy than the $d_{x y}, d_{x z}, d_{y z}$. For ions with between four and seven $d$ electrons, this gives rise to two possible arrangements called high-spin or low-spin (or weak-field or strong-field), respectively. The energy gap, $\Delta_{\text {oct }}$, is dependent on the position of the coordinated ligands in the spectrochemical series (Cotton et al., 2006). In tetrahedral complexes the orbitals are again split, such that two orbitals (the $d_{x^{2}-y^{2}}$ and the $d_{z^{2}}$ ) are now at lower energy than the remaining three. Tetrahedral complexes are all high spin since the difference between the two subsets of orbitals is much smaller than is found in octahedral complexes $\left(\Delta_{\text {tet }}=4 / 9 \Delta_{\text {oct }}\right)$. The "spin-only" formulae most frequently used to calculate magnetic moment of first row transition metal ion
complexes is given in Eq. 1.6. When the ground term for the metal ion is either $\mathrm{A}_{2 \mathrm{~g}}$ or $\mathrm{E}_{\mathrm{g}}$, spin-orbit coupling can "mix-in" some orbital degeneracy from higher T terms and in orbitally non-dengenerate systems $\left(d_{\text {tet }}^{1}, d_{\text {oct }}^{9} ; \mathrm{d}_{\text {tet }}^{2}, \mathrm{~d}_{\mathrm{oct}}^{8} ; \mathrm{d}_{\mathrm{tet}}^{3}, \mathrm{~d}_{\mathrm{oct}}^{7} ; \mathrm{d}_{\mathrm{tet}}^{4}, \mathrm{~d}_{\mathrm{oct}}^{6} ;\right.$ $\left.d_{\text {tet }}^{5}, d_{\text {oct }}^{5}\right)$ Eq. 1.7 is used.

$$
\begin{align*}
\mu_{\mathrm{eff}} \approx \mu_{\mathrm{spin}-\mathrm{only}} & =2 \sqrt{S(S+1)} \mu_{\mathrm{B}} \\
& =\sqrt{n(n+2)} \mu_{B} \tag{Eq. 1.6}
\end{align*}
$$

$$
\begin{equation*}
\mu_{\mathrm{eff}}=\mu_{\text {spin-only }}\left(1-\frac{\alpha \lambda}{\Delta}\right) \tag{Eq. 1.7}
\end{equation*}
$$

where $S$ is total spin (eg. $S=3 / 2$ for $\mathrm{d}^{3}$ ), $n$ is number of unpaired spins (eg. 3 for $\mathrm{d}^{3}$ ), $\alpha$ is a constant $=2$ for E and 4 for A ground terms, $\lambda$ is the spin orbit coupling constant, and $\Delta$ is the crystal field splitting parameter that can often be obtained from the visible spectrum of the complex. The calculated spin-only and experimental of magnetic moment data for some octahedral complexes are listed in Table 1.4. Note that Eq. 1.7 yields Curie-Weiss behavior (Eq. 1.4), except for $d_{\text {oct }}^{5}\left({ }^{6} \mathrm{~A}_{1 \mathrm{~g}}\right)$ which is Curie, and a small temperature dependent $\mu_{\text {eff }}$ results from Eq. 1.5 (Kahn, 1993).

Note also that the deviations from Eq. 1.7 that $\mu_{\text {obs }}$ show (eg. $\mathrm{Ni}(\mathrm{II})$ oct, $\mu_{\mathrm{obs}}$ ca. 3.1 $\mu_{\mathrm{B}} ; \mu_{\text {spin-only }}=2.83 \mu_{\mathrm{B}}$ ) depend on the size and sign of $\lambda$ (negative for $\mathrm{d}^{8}, \mathrm{Ni}(\mathrm{II})$ ) and on the size of $\alpha$ and $\Delta$. The $\mu_{\mathrm{obs}}$ values often, but not always, differ significantly for T ground term systems because the orbital degeneracy is affected directly by spin orbital coupling. Curie-Weiss law applies to $\chi_{\mathrm{M}}$ and $\Theta$ can be large and negative so that $\mu_{\text {eff }}$ varies with temperature.

Table 1.4 Comparison of calculated spin-only magnetic moments with experimental data for some octahedral complexes.

| Ion | Configuration | Ground term | $\mu_{\text {spin-only }}\left(\mu_{\mathrm{B}}\right)$ | $\mu_{\text {obs }}\left(\mu_{\mathrm{B}}\right)$ |
| :---: | :---: | :---: | :---: | :---: |

${ }^{[*]}$ Second order field effects (Zeeman), $H^{2}$, can give small positive $\mu_{\text {eff }}$ values, the corresponding $\chi_{\mathrm{M}}$ called "temperature independent susceptibility", TIP.

### 1.3.1 Classification of Magnetic Materials

The origin of magnetism lies in the orbital and spin motions of electrons, and how the electrons interact with one another and with the field, $H$. The magnetic moments associated with atoms have three origins. These are the electron orbital motion, the change in orbital motion caused by an external magnetic field, and the spin of the electrons. The magnetic behavior of materials can be classified into the following five major groups depending on their bulk magnetic susceptibility as shown in Figures 1.19 and 1.20. A summary of different types of magnetic behavior
for each type of material is listed in Table 1.5.
Diamagnetism: the substances are composed of atoms which have no net magnetic moments when there is no applied field, namely, all the orbital shells are filled, and there are no unpaired electrons (Figure 1.19a). However, when exposed to a field, they have a very weak and negative susceptibility to magnetic fields. Most elements in the periodic table, including d- and f-block metal ions are diamagnetic. Of importance here are the diamagnetic ligands.

Paramagnetism: the unpaired electrons are randomly arranged, Figure 1.19b. Their properties are due to the presence of some unpaired electrons, and from the of the electron orbits caused by the external magnetic field. However, when the field is removed, the individual magnetic moments do not interact magnetically (like diamagnetism), the magnetization is zero. Paramagnetic materials include most mononuclear d- and f-blocks complexes.

Ferromagnetism: the unpaired electrons are all aligned parallel (Figures 1.19 c , and 1.19 d ). The materials have a large and positive susceptibility to an external magnetic field. They exhibit a strong attraction to magnetic fields, and are able to retain their magnetic properties after the external field has been removed. Ferromagnetic materials have some unpaired electrons, and their atoms have a net magnetic moment. They get their strong magnetic properties due to the presence of magnetic domains. In these domains, the unpaired electron spins to line up parallel with each other in a region so that the magnetic force within the domain is strong. When a ferromagnetic material is in the unmagnetized state, the domains are nearly randomly organized, and the net magnetic field for the part as a whole is zero. When
a magnetizing force is applied, the domains become aligned to produce a strong magnetic field within the part.

All ferromagnets have a maximum temperature where the ferromagnetic property disappears as a result of thermal agitation. Below this temperature all spins are "ordered". This temperature is called the Curie temperature, $T_{\mathrm{C}}$ (Kahn, 1993; Miller and Drillon, 2002). Metals such as, $\mathrm{Fe}\left(T_{\mathrm{C}}=770^{\circ} \mathrm{C}\right), \mathrm{Co}\left(T_{\mathrm{C}}=1131^{\circ} \mathrm{C}\right)$ and $\mathrm{Ni}\left(T_{\mathrm{C}}=358{ }^{\circ} \mathrm{C}\right)$ are ferromagnetic at and above room temperature. The Curie temperature is an essential temperature for a ferromagnetic material. At temperature below the Curie temperature, the material has a net spontaneous magnetization, which means that the material becomes ferromagnetic, or "magnetic". If a ferromagnetic material is at a temperature above its Curie temperature, then the material becomes paramagnetic the spins are randomized, and it is no longer a "magnet".

Antiferromagnetism: the unpaired electron spins are lined up parallel opposite of one another (Figure 1.19e). The clue to antiferromagnetism is the behavior of susceptibility above a critical temperature, called the Néel temperature, $T_{\mathrm{N}}$ (Kahn, 1993; Miller and Drillon, 2002). Above $T_{\mathrm{N}}$, the susceptibility obeys the Curie-Weiss law for paramagnets but with a negative intercept $(\Theta)$ indicating negative exchange coupling interactions. Note that this is a different reason for negative $\Theta$ than described on page 38 for monomeric compounds. The only metallic element exhibiting antiferromagnetism at room temperature is chromium. Oxides such as MnO are classical antiferromagnets.

Ferrimagnetism: the electron spins are orientated antiparallel to one another but, due to an inequality in the number of spins in each orientation, there exists an
overall (net) magnetic moment, (Figure 1.19f). Ferrimagnetism is only observed in compounds which have more complex crystal structures than have pure the metallic elements. Metal oxides such as iron oxides are ferrimagnetic materials.

Figure 1.19 2-D representation of spin alignment for (a) diamagnet, (b) paramagnet, (c) ferromagnet, (d) canted ferromagnet, (e) antiferromagnet, and (f) ferrimagnet behavior. Redrawn after Miller and Epstein, 1994.

Figure 1.20 Schematic illustration of the magnetization, $M$, as a function of applied magnetic field, $H$, for several types of commonly observed in magnetic behavior. Redrawn after Miller et al., 1988.

Of particular relevance to the present study is the subject of molecular materials (molecular-based magnets) that has developed vigorously during the last twenty years. These d- or f-block metal-organic compounds contain, usually, bridging ligands (such as $\mathrm{CN}^{-}$) that "couple" spins on neighboring metal ions such that longrange order of the types shown in Figure 1.19 can occur below $T_{\mathrm{C}}$ (or $T_{\mathrm{N}}$ ) temperatures that are usually well below room temperature.

Table 1.5 Summary of different types of magnetic behavior.

| Type | Susceptibility, $\chi_{\mathrm{M}}$ | Atomic (metals) ${ }^{[a]}$ |
| :---: | :---: | :---: |
| Diamagnetic | Small \& negative | Atoms have no magnetic moment |
| Paramagnetic | Small \& positive | Atoms have randomly oriented magnetic moments |
| Ferromagnetic | Large \& positive, function of applied field ${ }^{[b]}$, microstructure dependent | Atoms have parallel aligned magnetic moments |
| Antiferromagnetic | Small \& positive close to zero | Atoms have mixed equal antiparallel aligned magnetic moments |
| Ferrimagnetic | Large \& positive, function of applied field, microstructure dependent | Atoms have anti-parallel aligned unequal magnetic moments |

${ }^{[a]}$ In "molecular" species such as d- or f-block metal complexes, organic radicals or metal-organic radicals, these kinds of magnetic behaviors are now known (Kahn, 1993)
${ }^{[b]}$ Note that in small cluster (ligand-bridged) complexes, ferromagnetic (or antiferromagnetic) coupling of spins, within the clusters does not involve long-range magnetic order and $\chi_{\mathrm{M}}$ does not depend on the field, $H$, thus ferromagnetic coupling does not mean the materials is an ordered ferromagnet (unless $T_{\mathrm{C}}$ can be observed at very low temperature).

### 1.3.2 Spin-Crossover (SCO) Compounds

Recently, research into the preparation and properties of complexes that exhibit the SCO phenomenon has been extensive due to their potential applications for molecular switches and information storage and display devices (Kahn and Martinez, 1998; Miller, 2003; Sato, 2003). SCO is quite frequently observed in octahedral complexes of some transition metal ions with electronic configurations of $3 d^{4}$ to $3 \mathrm{~d}^{7}$ (Gütlich and Goodwin, 2004; Bousseksou et al., 2007). These can adopt either a HS or a LS ground state depending on the ligand field strength relative to the mean spin-pairing energy (Gütlich et al., 1994). A crossover between these states is observed when the difference between the ligand field strength and the mean spinpairing energy is in the range of the thermal energy. As illustrated in Figure 1.21, this phenomenon can be induced by a change external constraints, i.e. temperature, pressure or electromagnetic radiation, Light-Induced Excited Spin State Trapping (LIESST) effect (Gütlich et al., 2005; Klokishner, and Linares, 2007; Grunert et al., 2008; Neville et al., 2008). Changes in colour, magnetic moment and structural properties (eg. metal-ligand distances) are observed when SCO occurs.

In addition to the inner coordination sphere (ligand) effects, the influence of anions, solvate molecules, noncovalent interactions will also affect the nature of SCO and the cooperativity (see below), as has been discussed above. The use of supramolecular chemistry to design such SCO materials have been extensively investigated (Yamada et al., 2006). These interactions can cause mechanical and/or electronic coupling of the centers, and thereby modify the properties of the materials cooperativity in solid materials is when the spin centers interact together. Strong cooperativity leads to an abrupt spin transition and/or thermal hysteresis, or it can
yield multiple stable states weak cooporativity leads to gradual spin transitions. Types of SCO are provided in Figure 1.22.

Ligand Field Strength
(a)

Fe-N Bond Length
(b)

Figure 1.21 Schematic illustration of an $\mathrm{Fe}($ II ) SCO complex, (a) d-orbital splitting and the electronic distribution in the low-spin and high-spin states in an octahedral ligand field, and (b) the corresponding osscillator potentials of the totally symmetric mode of the complex as well as showing bond length change between spin states. In SCO compounds the energy difference $\Delta E \approx k_{\mathrm{B}} T$ between the lowest vibronic levels and the much higher density of high-spin states leads to a reversible spin transition well below the decomposition temperature. Also light of different wavelengths switches between the low-spin and the metastable highspin state at low temperatures.

Figure 1.22 Various types of SCO transition. (a) smooth transition occurring within a few K , or a gradual transition occurring within a large temperature interval, (b) complete transition at both a low $\left(\chi_{\mathrm{HS}}=0\right)$ and a high temperature $\left(\chi_{\mathrm{HS}}=1\right)$, or incomplete at a low temperature $\left(\chi_{\mathrm{HS}}>0\right)$ or at a high temperature $\left(\chi_{\mathrm{HS}}<1\right)$, (c) transition with the thermal hysteresis effect, the critical temperature upon heating $T_{\mathrm{C}}$ is higher than that upon cooling $T_{\mathrm{C}}$, and (d) two-step (incomplete) SCO. $\gamma_{\mathrm{HS}}$ is the fraction of HS. Note that $T_{\mathrm{C}}=T_{1 / 2}$ is when $\gamma_{\mathrm{HS}}=\gamma_{\mathrm{LS}}=0.5$. Redrawn after Gütlich et al., 1994.

Table 1.6 Experimental methods used to monitor the SCO transition in eg. $\mathrm{Fe}^{\mathrm{II}}$ compounds.

| Experimental Methods | Monitored Property | LS | HS |
| :--- | :--- | :--- | :--- |
| Magnetic measurements | Magnetic susceptibility, <br> effective magnetic moment | Low | High |
| Calorimetric measurements | Heat capacity | Low | High |
| Mössbauer spectra | Quadrupole splitting, $\Delta E_{Q}$ | Low | High |
| X-ray diffraction | Cell parameters, | Low | High |
| Nuclear magnetic resonance | Paramagnetic shift, effective | Low | High |
| Volumetric measurements | Partial molar volume | Low | High |
| Vibrational spectra | M-L stretching wavenumber | High | Low |
| Electron spin resonance | Absorption, $g$-factor | No | Yes |
| Optical spectroscopy | Excitation energy | Low | High |
| LIESST (photomagnetism) | Photoexcited HS state | High | Low |

(Gütlich and Goodwin, 2004)

Several techniques used to directly monitor substances in the LS and the HS states spin state, and the monitored property, are summarised in Table 1.6. Typical results for a Fe (II) SCO from Mössbauer, IR $\left[v\left(\mathrm{Fe}^{\mathrm{II}}-\mathrm{N}\right)\right]$, and $\mathrm{d}-\mathrm{d}$ visible spectra techniques are also shown in Figure 1.23.

Figure 1.23 Typical temperature evolutions of (a) Mössbauer, (b) Infrared, and (c) Electronic d-d visible spectra for a SCO system of $\mathrm{Fe}(\mathrm{II})$. Redrawn after Gütlich and Goodwin, 2004.

Mononuclear Fe(II) complexes with six N (pyridyl type) donor have been extensively studied, and many modern aspects have been recovered (Gütlich and Goodwin, 2004). Recently, interest has been turned to polynuclear species, particularly of $\mathrm{Fe}(\mathrm{II})$. Representative examples of SCO are dinuclear $\mathrm{Fe}(\mathrm{II})$ compounds which recent reports by the group of Murray (2008), Leita et al. (2004; 2007), Klingele et al. (2005), Amoore et al. (2006), and Schneider et al. (2007), the group of Kaizaki, Nakano et al. (2004), Nakano et al. (2005), Yoneda et al. (2006), and the group of Real, Ortega-Villar et al. (2005), Gaspar et al. (2006), Bousseksou et al. (2007). The spin transitions in these dinuclear Fe(II) systems proceed through [HS-HS] $\leftrightarrow[\mathrm{HS}-\mathrm{LS}] \leftrightarrow[$ LS-LS] or by the direct [HS-HS] $\leftrightarrow[$ LS-LS] transformations.

Recently, great progress has been made in the area of SCO complexes that display infinite 1-D to 3-D coordination polymeric arrays (Murray and Kepert, 2004; Gaspar et al., 2005; Mroziński, 2005; Molnár et al., 2007). The purpose of this polymers approach was to try and enhance, and fine tune of cooperative properties by the strong covalent links between the metallic centers in the polymers. Murray and co-workers have reported the synthesis series of four isostructural 1-D polymeric Fe(II) SCO materials containing the ligand 2-chloro-4,6-bis(dipyrid-2-ylamino)-1,3, 5-triazine (cddt) (Neville et al., 2007; Murray, 2008). Reedijk and co-workers have used the 1,3-bis(tetrazol-1-yl)-2-propanol (btzpol) ligand with $\mathrm{Fe}\left(\mathrm{BF}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, in $\mathrm{CH}_{3} \mathrm{CN}$, to yield the remarkable 2-D coordination polymer $\left[\mathrm{Fe}(\text { btzpol })_{1.8}\right.$ (btzpol$\left.\left.\mathrm{OBF}_{3}\right)_{1.2}\right]\left(\mathrm{BF}_{4}\right)_{0.8} \cdot\left(\mathrm{H}_{2} \mathrm{O}\right)_{0.8} \cdot\left(\mathrm{CH}_{3} \mathrm{CN}\right)$. It shows spin-transition properties induced by both temperature and light (Quesada et al., 2007).

A beautiful example of a 3-D coordination polymer incorporating SCO Fe(II) centers is found in the $\alpha$-Po like structure of $\left[\left\{\mathrm{Fe}(\mathrm{pbtz})_{3}\right\}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 2 \mathrm{EtOH}\right]$, where pbtz is the 2-connecting di-tetrazole 1,3-di(tetrazol-2-yl)propane, Figure 1.24, was reported by Bronisz (2007), and provided the opportunity to characterize the mixed LS-HS spin state by X-ray crystallography. The single crystal X-ray diffraction studies at 90 K have confirmed that the structure undergoes the thermally induced spin transition HS $\leftrightarrow$ LS. The $\chi_{\mathrm{M}} T$ dependence in the range $200-75 \mathrm{~K}$ shows a gradual SCO. Below 75 K , the transition is complete, and $c a .20 \%$ of the HS fraction is presented in the LS sample. The HS $\rightarrow$ LS transition is accompanied by a shortening of the $\mathrm{Fe}-\mathrm{N}$ bonds of $0.15 \AA$. The 2-connecting di-tetrazoles such as pbtz are relevanted to the present work the same 2-connecting di-organonitriles have been used to make Fe (II) SCO network, as described in Chapter VI of this thesis.

Figure 1.24 (a) Coordination environment of $\mathrm{Fe}(\mathrm{II})$ ions and (b) a schematic presentation of the 3-D $\alpha$-Po like network in $\left[\left\{\mathrm{Fe}(\mathrm{pbtz})_{3}\right\}\left(\mathrm{ClO}_{4}\right)_{2}\right]$ $\cdot 2 \mathrm{EtOH}, \mathrm{pbtz}$ molecules represented as green solid lines. Perchlorate anions and ethanol molecules are omitted for clarity. Drawn from coordinates from CSD, after Bronisz, 2007.

Other coordination compounds of 3 d transition elements such as $\mathrm{Cr}^{\mathrm{II}}, \mathrm{d}^{4}$ (Halepoto et al., 1989; Meredith et al., 2006), $\mathrm{Fe}^{\mathrm{III}}, \mathrm{d}^{5}$ (Imatomi et al., 2007), $\mathrm{Mn}^{\mathrm{II}}, \mathrm{d}^{5}$ (Hebendanz et al., 1986), $\mathrm{Mn}^{\mathrm{III}}, \mathrm{d}^{4}$ (Morgan et al., 2006), $\mathrm{Co}^{\mathrm{II}}, \mathrm{d}^{7}$ (Brooker et al., 1999; Krivokapic et al., 2007), and $\mathrm{Co}^{\text {III }}$, d ${ }^{6}$ (Klaeui et al., 1987; Wasbotten and Ghosh, 2007) were also found the similar SCO phenomena.

### 1.3.3 Cyanometallate Building Blocks in Molecular Magnetic Materials

The engineering of molecular magnetic systems may be considered as a facet of supramolecular chemistry, since it results from the collective features of components bearing free spins and on their arrangement in organized assemblies. The approach requires the judicious choice of the building blocks and their arrangement in suitable supramolecular architectures.

During recent years, bridging cyanometallate units have been used in concert with coordinately unsaturated complexes of simple transition metal ions to create multidimensional supramolecular polymers which exhibit very interesting spectroscopic, magnetic, and magnetooptical properties. Some recent literatures are found in papers by Beltran and Long (2005), Sieklucka et al. (2005), and Przychodzeń et al. (2006).

Prussian blue (PB), $\left[\mathrm{Fe}^{\mathrm{III}}{ }_{4}\left\{\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right\}_{3}\right] \cdot x \mathrm{H}_{2} \mathrm{O}$, is the iconic and original $\mathrm{CN}^{-}$ linked coordination compound. This complex was synthesized many years ago by mixing together the aqueous solutions of $\mathrm{K}_{4}\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]$ and $\mathrm{Fe}(\mathrm{III})$ chloride affording a beautiful deep-blue color. The structure, Figure 1.25, is a mixed-valence cyanidebridged cubic network containing LS Fe ${ }^{\text {II }}(S=0)$ surrounded by carbon and HS Fe ${ }^{\text {III }}$ ( $S=5 / 2$ ) linked to the nitrogen atoms of the cyanide bridge (Buser et al., 1977). It orders ferromagnetically below $T_{\mathrm{C}}=5.6 \mathrm{~K}$ (Herren et al., 1980). Using the same
approach, closely framework compounds related to PB with interesting magnetic properties have also been synthesized by the reaction of hexacyanometalates $\left[\mathrm{M}^{\mathrm{III}}(\mathrm{CN})_{6}\right]^{3-}, \mathrm{M}^{\mathrm{III}}=\mathrm{Cr}, \mathrm{Mn}, \mathrm{Fe}$, and Co , with transition metal Lewis acid aqua salts, $\mathrm{M}^{\mathrm{II}}=\mathrm{Mn}, \mathrm{Co}, \mathrm{Ni}$, and Cu (Miller and Drillon, 2005).

The most common problem dealing with the characterization of PB related compounds is their poor crystallinity and consequently, the difficulty in growing single crystals. Moreover, although the PB phases exhibit remarkable magnetic properties, their face-centerd cubic structures mean that no magnetic anisotropy can be expected. In an attempt to address this problem, a number of research groups have turned their attention to investigate Prussian blue analogs (PBs) and developed an alternative synthetic route that commonly involves the reaction of a cyanometallate such as $\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{CN})_{6}\right]^{3-}$ with a metal chelate such as $\left[\mathrm{Ni}(\mathrm{en})_{3}\right]^{2+}$. Many such heterometallic frameworks have been reported with reviews by Kahn et al. (1993).

Figure 1.25 A schematic presentation of the 3-D cubic network in Prussian blue.

Chelated metal-cyano species have been used to direct the topology and nuclearity of clusters and extended networks. In clusters such as squares, a tetradentate chelate can block four positions around the M ions, eg. in $\left[\mathrm{M}(\mathrm{tpa})(\mathrm{CN})_{2}\right]$ to react with $\left[\mathrm{M}^{\prime}(\mathrm{tpa})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ or $\left[\mathrm{M}^{\prime}\left(2,2^{\prime}-\text { bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$, where tpa $=\operatorname{tris}(2-$ pyridylmethyl)amine, to yield the square (Nihei et al., 2005). In cubes, use of a facial tridentate ligand will leave three facial sites pointing in toward the cube eg. $\left[\mathrm{M}^{\mathrm{II}}(\operatorname{tacn})(\mathrm{CN})_{3}\right]^{-}$for reaction with $\left[\mathrm{Mn}(\operatorname{tacn}) \mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right]^{2+}$, where tacn $=1,4,7-$ triazacyclononane, to yield CN-bridged cubes (Beltran and Long, 2005). Thus, one of the initial aim of the present study was to use bidentate chelates in precursors such as $\left[\mathrm{M}(\mathrm{en})(\mathrm{CN})_{4}\right]^{2-}$ to produce CN -bridged square tube species upon reaction with $\left[\mathrm{M}(\text { bidentate })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$. The background to such precursor is given.

The detailed investigation of compounds requires a combination of a number of different experimental techniques (eg. chemical analysis, infarared spectroscopy, single and powder X-ray diffraction, etc.) and the theoretical description of the electronic structure obtained from magnetic, spectral, Mössbauer (Fe), and EPR methods.

### 1.3.4 $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]$ Building Blocks

To investigate the structure and magnetic properties of low dimensional PBs compounds, a few research groups have recently explored the possibilities of using the mononuclear precursor of formula $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]^{z^{-}}$, where $z=1,2 ; \mathrm{M}=\mathrm{Cr}^{\mathrm{III}}, \mathrm{Fe}^{\mathrm{II}}$, $\mathrm{Fe}^{\text {III }}$, and $\mathrm{Ru}^{\mathrm{II}}, \mathrm{L}=$ bidentate nitrogen donor, i.e. 1,10-phenanthroline (1,10-phen), 2-aminomethylpyridine (ampy), 2,2'-bipyridine (2,2'-bipy), 4,4'-dimethyl-2,2'bipysridine (dmbpy), as building blocks toward transition metal ions. Julve and coworkers have reacted a $1: 1$ molar ratio of the $\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$and
$\left[\mathrm{M}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$, where $\mathrm{M}^{\text {II }}=\mathrm{Mn}$ and Zn , in aqueous solution to afford trinuclear neutral complexes with formula $\left[\left\{\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right\}_{2} \mathrm{M}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$, where M $=\mathrm{Mn}$ and Zn (Lescouëzec et al., 2002). In the structure of the centrosymmetric trinuclear species, the $\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$unit acts as a monodentate ligand toward $\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}(\mathrm{M}=\mathrm{Mn}$ and Zn$)$ through one cyanide group, the other three ones remaining terminal. The intramolecular $\mathrm{Fe}-\mathrm{M}$ distances are $5.126(1)(\mathrm{Mn})$ and $5.018(1) \AA(\mathrm{Zn})$. The analysis of the magnetic properties of both compounds show the occurrence of very weak antiferromagnetic behaviors. More interestingly, the manganese derivative show the occurrence of very weak antiferromagnetic interactions between the adjacent LS Fe(III) and HS Mn(II) ions through the bridging cyanide $\left(J=-0.9 \mathrm{~cm}^{-1}\right)$ and between the peripheral LS Fe(III) ions through the $-\mathrm{CN}-\mathrm{Mn}-\mathrm{NC}-$ bridging framework $\left(J^{\prime}=-1.3 \mathrm{~cm}^{-1}\right)$.

In a similar study by the same group, the use of $\left[\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$with the fully hydrated $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ or $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ in aqueous solution in $1: 1$ stoichiometry yielded the isostructural 4,2-ribbon like bimetallic chain of formula $\left[\left\{\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right\}_{2} \mathrm{M}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{M}=\mathrm{Co}($ Lescouëzec et al., 2003) and Cu (Toma et al., 2004). The crystal structures of these two complexes are made up of neutral cyanide-bridged $\mathrm{M}^{\mathrm{II}}-\mathrm{Fe}^{\mathrm{III}}$ double zigzag chains and uncoordinated water molecules which are linked through van der Waals forces and hydrogen bonds. Within each chain, the $\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$entity acts as a bismonodentate ligand towards two trans-diaquametal(II) units through two of its four cyanide groups in cispositions affording bimetallic double chains which run parallel to the $a$ axis as illustrated in Figure 1.26. The magnetic behavior corresponds to that of a ferromagnetically coupled chain of $\mathrm{LS} \mathrm{Fe}(\mathrm{III})$ and $\mathrm{M}(\mathrm{II})$ ions with frequency
dependence of the out-of-phase AC susceptibility at $T<8.0$ and 4.0 K for $\mathrm{M}^{\mathrm{II}}=\mathrm{Co}$ and Cu , respectively, which indicating that they are examples of single chain magnets (SCMs).

Figure 1.26 Perspective view of a fragment of the 4,2-ribbon like chain in [\{Fe ${ }^{\text {III }}$ $\left(2,2^{\prime}\right.$-bipy $\left.\left.)(\mathrm{CN})_{4}\right\}_{2} \mathrm{M}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{M}^{\mathrm{II}}=\mathrm{Co}$ and Cu . Hydrogen atom and isolated water molecules are omitted for clarity. Drawn from coordinates from CSD, after Lescouëzec et al., 2003.

Using the LS Fe(III) precursor, Julve and co-workers have also used the related chelate species of $\left[\mathrm{Fe}^{\mathrm{III}}(1,10 \text {-phen })(\mathrm{CN})_{4}\right]^{-}$as building block with the fully hydrated species $\left[\mathrm{M}_{\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}}\right.$ to synthesized an impressive series of cyanide-bridged bimetallic coordination polymers with interesting magnetic properties: the 4,2-ribbon like of formula $\left[\left\{\mathrm{Fe}^{\text {III }}(1,10 \text {-phen })(\mathrm{CN})_{4}\right\}_{2} \mathrm{M}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{M}=\mathrm{Mn}, \mathrm{Zn}$ (Lescouëzec et al., 2001), Co (Lescouëzec et al., 2003), and Ni (Toma et al., 2007). The Mn structure exhibits 1-D ferrimagnetic behaviour due to the non-compensation of the local interacting spins ( $S_{\mathrm{Mn}}=5 / 2$ and $S_{\mathrm{Fe}}=1 / 2$ ) which interact antiferromagnetically through the bridging cyano groups. The magnetic properties of Zn
structure correspond to the sum of two magnetically isolated spin triplets, the magnetic coupling between the $\mathrm{LS} \mathrm{Fe}(\mathrm{III})$ centers through the $-\mathrm{CN}-\mathrm{Zn}-\mathrm{NC}-$ bridging skeleton ( $\mathrm{Fe} \cdots \mathrm{Fe}$ separation larger than $10.2 \AA$ ) being negligible. The Co and Ni analogue exhibit ferromagnetically coupled chain of low spin Fe(III) and M(II) ions with frequency dependence of the out-of-phase AC susceptibility at $T<8.0$ and 3.5 K , respectively, again indicating of SCMs behavior.

In an attempt to extend cyanide bridging chemistry to the molecular regime, the Julve group has also used quite stable paramagnetic of cyanide-bearing $\operatorname{Cr}(\mathrm{III})$ building blocks $\left(S_{\mathrm{Cr}}=3 / 2\right)$ of the formula $\left[\mathrm{Cr}^{\mathrm{III}}(\mathrm{L})(\mathrm{CN})_{4}\right]^{-}$, where $\mathrm{L}=1,10$-phen, 2, $2^{\prime}-$ bipy, and ampy, towards fully hydrated $\mathrm{Mn}(\mathrm{II})$ ions afforded a wide variety of topologies of polynuclear species with interesting magnetic properties: the neutral trinuclear species $\left[\left\{\mathrm{Cr}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ and two 1-D compounds of formula $\left[\left\{\mathrm{Cr}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \quad$ and $\quad\left[\left\{\mathrm{Cr}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\right.$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{CH}_{3} \mathrm{CN}$ (Toma et al., 2004), and the 4,2-ribbon-like bimetallic chains $\left[\left\{\mathrm{Cr}(1,10 \text {-phen })(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ and $\left[\left\{\mathrm{Cr}(\mathrm{ampy})(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (Toma et al., 2005).

Related to the research mentioned above, recent work by Gao and co-workers have used the same building blocks of $\left[\mathrm{Cr}^{\text {III }}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$with secondary and/or tertiary coligands as modulators to synthesized a large family of multinuclear polymeric complexes as well as many topologies, but not 1-D tube species. These compounds in general exhibit antiferromagnetic interactions and either long-rang magnetic ordering including metamagnetism over the lattice, depending on the magnetic interactions (Zhang et al., 2004; 2005; 2006).

Very recently, Cheng and co-workers reported an impressive example of what they described as carbon nanotube (CNT)-like structure bridged by cyanide groups which has been first observed in coordination polymers (Xia et al., 2007). When the $\mathrm{K}_{2}\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right]$ building block with $\mathrm{MnCl}_{2}$ in a $1: 1$ stoichiometry were selfassembled in aqueous solution, orange cube-like crystals of $\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $)(\mathrm{CN})_{4}$ $\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] were formed. In the solid state structure, three $\mathrm{Mn}(\mathrm{II})$ ions and three $\mathrm{Ru}(\mathrm{II})$ ions form a basic hexanuclear unit, $\mathrm{Ru}_{3} \mathrm{Mn}_{3}$, bridged by cyanide groups with the distance between $\mathrm{Mn}(\mathrm{II})$ and $\mathrm{Ru}(\mathrm{II})$ ions being $4.969 \AA$. All the hexanuclear units are assembled alternately to form an infinite 1-D single (hexagonal tube) pipe structure as shown in Figure 1.27. The magnetic susceptibilities of this compound obey the Curie-Weiss law, which indicated paramagnetic $\operatorname{Mn}(\mathrm{II})$ ion ( $S=5 / 2$ ) behaviour. It can be ascribed to the diamagnetic nature of $\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$, and the $\mathrm{Mn}-\mathrm{Mn}$ interaction through the long diamagnetic $\mathrm{NC}-\mathrm{Ru}-\mathrm{CN}$ bridge (more than $10 \AA$ ) is very weak. Interestingly, this compound exhibits high thermal stability and does not decompose until $500^{\circ} \mathrm{C}$.

It is interesting to note, but different to provide the reason for the different structures and topologies that $\left\{\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]^{2-}+\left[\mathrm{M}^{\prime}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}\right\}$ reaction yield in contrast to our proposed use of $\left[\mathrm{M}^{\prime}(\mathrm{L})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ acceptors, there is no chelate directing or blocking preference using $\left[\mathrm{M}^{\prime}(\mathrm{L})\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$.

Figure 1.27 (a) Side and (b) top views of a CNT-like coordination hexagonal tube structure in $\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$. Drawn from coordinates from CSD, after Xia et al., 2007.

### 1.3.5 $\left[\mathrm{M}^{\text {II }}(\mathrm{CN})_{4}\right]^{\mathbf{2 -}}$ Building Blocks

Real and co-workers reported the syntheses and characterization of cyanidebridged bimetallic 3-D Hofmann-like networks with cooperative SCO behaviour of formula $\left[\mathrm{Fe}^{\mathrm{II}}(\right.$ pyz $\left.) \mathrm{M}^{\mathrm{II}}(\mathrm{CN})_{4}\right] \cdot n \mathrm{H}_{2} \mathrm{O}$, where pyz $=$ pyrazine, $\mathrm{M}=\mathrm{Ni}, n=2 ; \mathrm{Pd}, n=2.5$, and Pt, $n=2.5$ (Niel et al., 2001). The samples were obtained as microcrystalline materials when a solution of $\mathrm{K}_{2}\left[\mathrm{M}(\mathrm{CN})_{4}\right]$ in distilled $\mathrm{H}_{2} \mathrm{O}$ is added with constant stirring to a solution which contains stoichiometric amounts of pyz and $\mathrm{Fe}\left(\mathrm{BF}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ in $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ (1:1). They have exactly the same X-ray powder diffraction patterns. Ab initio crystal structure studies were carried out in order to confirm their 3-D nature in the absence of single crystals. The structure consists of the pyz ligands bridging the $\mathrm{Fe}(\mathrm{II})$ atoms of consecutive sheets thus achieving a pillaring of the 2-D sheets by vertical columns of the pz bridge to give a 3-D overall structure, Figure 1.28. Subsequently, the authors have also reported spectroscopic evidence for light-induced spin transition at room temperature in $\left[\mathrm{Pt}(\mathrm{CN})_{4} \mathrm{Fe}\right.$ (pyz)] $2 \mathrm{H}_{2} \mathrm{O}$ by applying a one-shot laser pulse of irradiation (Bonhommeau et al., 2005).

The absorption and/or desorption of guest molecules may reveal potential applications in the areas of separation and catalysis. Iwamoto and co-workers have used tetracyanonickelate(II) as building block to synthesize the Hofmann type clathrate (porous) framework, which are potentially useful as analogues of zeolites. The authors showed that the rigidity of the Hofmann type frameworks allows for shape and size selective inclusion of organic solvents or water molecules to fill up the void space stabilizing the crystal structure (Nishikiori and Iwamoto, 1986; Yuge and Iwamoto, 1993; 1994; Yuge et al., 1995; 1996). Particularly typical in porous CN-
bridged (PB) framework is the study of their hydrogen absorbing capacity. Kepert et al. (2005) and Long et al. (2006) have recently reported encouraging results on such species.

From the magnetic point of views, the tetracyanometallate moieties, generally formed by $\mathrm{d}^{8}$ metal ions, are LS and diamagnetic. Currently, the use of square planar $\left[\mathrm{M}(\mathrm{CN})_{4}\right]^{2-}$ building blocks has received little attention for designing magnetically ordered coordination polymers in contrast to their importance in SCO studies (Boldog et al., 2008).

Figure 1.28 Perspective view of the structure of cyanide-bridged bimetallic 3-D Hofmann-like networks in $\left[\mathrm{Pt}(\mathrm{CN})_{4} \mathrm{Fe}(\mathrm{pyz})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Drawn from coordinates from CSD, after Niel et al., 2001.

### 1.3.6 $\left[\mathbf{M}^{\mathbf{I}}(\mathbf{C N})_{2}\right]^{-}$Building Blocks in Framework Systems

The polycyanide anions like $\left[\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right]^{-}$, where $\mathrm{M}^{\mathrm{I}}=\mathrm{Ag}, \mathrm{Au}$, or Cu , are of particular interest when used as bridging ligands for the construction of multidimensional cyanometalate coordination polymers having interesting magnetic properties. They have shown versatile abilities to coordinate to metal ions in different modes and numbers such as (i) rod-shaped or a linear bridging motif (Dong et al., 2003), (ii) a discrete anion playing the role of space filler (Omary et al., 1996), and (iii) as a unidentate ligand that blocking some coordination sites of the central atom (Soma and Iwamoto, 1998).

Unlike other related two-connecting bridging ligands such as the non-metallic dicyanamide $\left[\mathrm{N}(\mathrm{CN})_{2}\right]^{-}$(Batten and Murray, 2003), interestingly, the $\left[\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right]^{-}$can also possess the ability to further stabilize the polymeric structures through interactions between closed-shell $\mathrm{d}^{10 \cdots \mathrm{~d}^{10}}$ argentophilic $\left(\mathrm{Ag}^{1} \cdots \mathrm{Ag}^{\mathrm{I}}\right.$ ) which has effectively increased its dimensionality from a 1-D chain to a 3-D network structure (Pyykko, 1997; Liu et al., 2006).

During recent years, Real and co-workers have systematically been investigating new Hofmann type Fe(II) SCO compounds with polymeric structures based on $\left[\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right]^{-}$(where $\mathrm{M}^{\mathrm{I}}=\mathrm{Ag}$ or Au ) as bridging ligands. By doing so, the authors have shown a number of beautiful examples in which those materials offer the opportunity to investigate the interplay between different switchable molecular and/or supramolecular components, and the collective properties that may arise from the synergy between the individual component properties. Compounds combine their cooperative SCO properties (magnetic, spectral chromatic, and structural) with different chemical properties such as crystalline-state reactions with allosteric effects

Figure 1.29 (a) A fragment in $\left[\mathrm{Fe}(3-\mathrm{I}-\mathrm{py})_{2}\left\{\mathrm{Au}(\mathrm{CN})_{2}\right\}_{2}\right] \cdot 0.5(3-\mathrm{I}-\mathrm{py})$, (b) packing with emphasizing the aurophilic interactions (dotted green lines). Drawn from coordinates from CSD, after Agustí et al., 2008.
found in $\left[\mathrm{Fe}(\mathrm{pmd})\left(\mathrm{H}_{2} \mathrm{O}\right)\left\{\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right\}_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{M}^{\mathrm{I}}=\mathrm{Ag}$ and $\mathrm{Au}, \mathrm{pmd}=$ pyrimidine, (Niel et al., 2003), SCO tuned metallophilicity as in $[\mathrm{Fe}(3-\mathrm{cyanopyridine})\{\mathrm{Ag}$ $\left.\left.(\mathrm{CN})_{2}\right\}_{2}\right] \cdot 1 / 3 \mathrm{H}_{2} \mathrm{O}$ (Galet et al., 2003), triple-interpenetrated 3-D network of [Fe(pmd) $\left.\mathrm{Ag}_{2}(\mathrm{CN})_{3} \mathrm{Ag}(\mathrm{CN})_{2}\right]$, which display a thermal and light induced spin transition and spin dependent ligand unsupported argentophilic interactions (Niel et al., 2005). A great series of compounds cooperative with SCO behaviours of formulated [Fe(3-Xpy) $\left.)_{2}\left\{\operatorname{Ag}(\mathrm{CN})_{2}\right\}_{2}\right]$, where $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, and I; py $=$ pyridine, and $\left[\left\{\mathrm{Fe}(3-\mathrm{X}-\mathrm{py})_{2}\right.\right.$ $\left.\operatorname{Ag}(\mathrm{CN})_{2} \operatorname{Ag}(3-\mathrm{X}-\mathrm{py})(\mathrm{CN})_{2}\right] \cdot 3-\mathrm{X}$-py, where $\mathrm{X}=\mathrm{Br}$ and I , have also been synthesized (Munoz et al., 2007). Very recently, the clathrate derivative [Fe(3-I-py) ${ }_{2} \mathrm{Au}$ $\left.\left.(\mathrm{CN})_{2}\right\}_{2}\right] \cdot 0.5(3-\mathrm{I}-\mathrm{py})$ was reported by the same group. The structure is made up of parallel stacks of corrugated $\left[\operatorname{Fe}\left\{\operatorname{Au}(\mathrm{CN})_{2}\right\}_{2}\right]_{n}$ grids and cross-link via aurophilic interactions to give 3-D networks structure, Figure 1.29.

### 1.4 Metal Oxides Framework Materials: Vanadates

Inorganic oxide materials have attracted considerable interest over many years owing to their intriguing structures and wide potential applications in a variety of areas such as those listed in Table 1.7. Recently, inorganic oxides have been used to produce functional nanosystems, an area representing on of the greatest challenges in physics, chemistry and materials science (Wight and Davis, 2002; Rao et al., 2004). Control over the cluster arrangements in the molecular-assemblies is important in allowing the construction of solid state inorganic oxides of nanoscale dimensions, and these aspects have been discussed recently (Akutagawa et al., 2007; Alam et al., 2008).

### 1.4.1 Hydrothermal Synthesis of Hybrid Organic-Inorganic Framework Materials

One approach to the rational design and syntheses of solid frameworks is to mimic nature's use of organic molecules to modify inorganic structures (Cheetham et al., 1999). Organic templates may be used to introduce secondary inorganic metal sites. Of particular use are aliphatic amines which can have multiple roles, such as (i) space-filling, (ii) charge-compensating, or (iii) structure directing, dependent on their coordination preferences and range of binding interactions (Hagrman et al., 1999). The use of organic templates in the fabrication of self-assembled frameworks has long been used in zeolite synthesis, and has recently been demonstrated for a number of metal oxide frameworks made using hydrothermal synthetic methods (Hagrman et al., 2001). Reactions are typically performed in the temperature range $110-240{ }^{\circ} \mathrm{C}$ under autogenous pressure in a sealed reaction vessel (Byrappa and Ohachi, 2007). This allows the self-assembly of the products from precursors which would be insoluble or unreactive under ambient conditions. Different phase pure products are obtained by changing physical conditions such as pH , stoichiometry, temperature, time, and concentration (Law and Williams, 2000; Forster et al., 2005). This approach has produced a variety of hybrid metal oxide structures (eg. 0-D discrete clusters, 1-D infinite chains, 2-D sheets, and 3-D frameworks) with potential functionality (Zavalij and Whittingham, 1999).

Table 1.7 Selected examples and applications of inorganic oxides.

| Metal class | Examples | Applications |
| :---: | :---: | :---: |
| Magnetic Oxides | $\mathrm{CrO}_{2}$, ferrites, spinels | Magnetic tapes, transformer cores, computer memories |
| Oxide sensors | $\mathrm{BaTiO}_{3}, \mathrm{PbZrO}_{3}$ | Temperature sensors, piezo spealers |
| Phosphors | $\begin{aligned} & \text { Doped } \mathrm{Zn}_{2} \mathrm{SiO}_{4}, \\ & \mathrm{Y}_{2} \mathrm{O}_{3} \end{aligned}$ | Oscilloscope tubes |
| Electronic materials | $\mathrm{BaTiO}_{3}, \mathrm{ZnO}$ | Surge protectors, high T semiconductors |
| Ceramics | $\begin{aligned} & \mathrm{Al}_{2} \mathrm{O}_{3}, \\ & \mathrm{PbZr}_{1-x} \mathrm{Ti}_{x} \mathrm{O}_{3} \end{aligned}$ | Ferroelectrics |
| Catalysts | $\begin{aligned} & (\mathrm{VO})_{2} \mathrm{P}_{2} \mathrm{O}_{7}, \mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}, \\ & \mathrm{~V}_{2} \mathrm{O}_{5} / \mathrm{TiO}_{2} \end{aligned}$ | Selective oxidations, oxidative dehydrogenation, polymerization |
| Ion exchange | NASICON, zeolites | Fast ion conductors, detergents |
| Molecular sieves | Zeolites | Separating agents |
| Biomaterials | Organoapatites | Artificial bone |
| Optical materials | $\mathrm{LiNbO}_{3}, \mathrm{KTiOPO}_{4}$, Nd: YAG | Harmonic generators, frequency mixers, lasers |
| Construction oxides | CaO | Concrete, trap for desulfurization |
| High temperature materials | Vitreous silica | $1000-1300{ }^{\circ} \mathrm{C}$ containers |

Hagrman et al., 2001

### 1.4.2 Organovanadium Framework Materials of Relevance to the Present Thesis

Vanadium is often found in oxides in all the oxidation states $(+5),(+4),(+3)$, and even (+2). In mineral chemistry, vanadium exhibits three oxidation states $\mathrm{V}^{(+5)}$, $\mathrm{V}^{(+4)}$, and $\mathrm{V}^{(+3)}$ which gives many isopolyvanadates that exhibits a large variety of structures. The structure of the frameworks shown schematically in Figure 1.30 is defined in substantial part by the vanadium-oxygen coordination polyhedra, which
vary from tetrahedron to trigonal pyramid, square pyramid, distorted octahedron and regular octahedron, while the oxidation state change from ( +5 ) to ( +3 ), with vanadium-oxygen doubling bonding playing a part in the $(+5)$ and $(+4)$ states.

(b)
(c)

Figure 1.30 Metamorphosis of the vanadium coordination polyhedra: (a) tetrahedral, (b) " $3+2$ " and " $4+1$ " trigonal pyramidal, (c) " $4+1$ " square pyramidal, (d) " $4+1+1$ " and " $2+2+2$ " distorted octahedral, and (e) regular octahedral. Redrawn after Zavalij and Whittingham, 1999.

The synthesis of extended structure solids based on vanadium oxides is of much currently interest. This is mainly due to their fascinating structures and attractive possibilities for their catalytic or magnetic properties $\left(\mathrm{V}^{+4}, \mathrm{~V}^{+3}\right)$, and the development of new cathode materials for Li batteries (Liu et al., 2002; Weckhuysen and Keller, 2003). Many interesting new systems containing tetrahedral $\left\{\mathrm{VO}_{4}\right\}$,
square pyramidal $\left\{\mathrm{VO}_{5}\right\}$, and octahedral $\left\{\mathrm{VO}_{6}\right\}$ units with vanadium centers have been synthesized and characterized. The tetrahedral $\left\{\mathrm{VO}_{4}\right\}$ linking unit is often observed among the solid state polyhedra of vanadium oxide structures. This is analogous to the use of $\mathrm{AlO}_{4}$ and $\mathrm{SiO}_{4}$ in aluminasilicate based zeolites, tetrahedral oxyanions such as $\mathrm{PO}_{4}^{3-}, \mathrm{SO}_{4}^{2-}$, and $\mathrm{AsO}_{4}^{3-}$, and tetrahedral $\left\{\mathrm{ZnO}_{4}\right\}$, which can produce similar topologies. The tetrahedral $\left\{\mathrm{VO}_{4}\right\}$ unit may be regarded as a potentially versatile motif for constructing oxovanadate based open framework solid structures. These could be remarkable redox catalysts unlike zeolites that do not show such characteristic reactivity and redox chemistry (Whittingham, 2004).

Several open-frameworks of vanadate solids can be prepared by self-assembly of three main building blocks, i.e. an organoamine ligand, a transition metal cation, and an oxovanadate, under mild hydro/solvothermal conditions. In 1996, Zubieta and co-workers reported a new class of hydrothermally synthesized mixed-valence vanadium oxides that possesses a layered structure and displayed interesting ionexchange and magnetic properties (Zhang et al., 1996). Williams and co-workers prepared the first example of 3-D organically templated manganese divanadates of $\left[\mathrm{H}_{2} \mathrm{en}\right]\left[\mathrm{Mn}_{3}^{\mathrm{II}}\left(\mathrm{V}_{2}^{\mathrm{V}} \mathrm{O}_{7}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ by hydrothermal reaction of $\left[\mathrm{Mn}_{3} \mathrm{O}(\mathrm{OAc})_{6}\left(\mathrm{py}_{3}\right)_{3}\right]\left[\mathrm{BF}_{4}\right]$, $\mathrm{V}_{2} \mathrm{O}_{5}$, en, and $\mathrm{H}_{3} \mathrm{BO}_{3}$ in a 0.67: 1: 6: 10 ratio with $\mathrm{pH}=8$ at $140{ }^{\circ} \mathrm{C}$. This compound was of magnetic interest, since the $\mathrm{Mn}^{\mathrm{II}}$ centers associated as trimers or ladder-like chains, Figure 1.31. Subsequently, a vast of polymeric metal oxide framework materials with interesting properties has been recently discovered (Chesnut et al., 1999; Wight and Davis, 2002; Coronado et al., 2005; Akutagawa et al., 2007).

Figure 1.31 Polyhedral and ball-stick representations in $\left[\mathrm{H}_{2} \mathrm{en}\right]\left[\mathrm{Mn}_{3}\left(\mathrm{~V}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$. The $\left[\mathrm{enH}_{2}\right]^{2+}$ group are in the cavities. Hydrogen atoms are omitted for clarity. Drawn from coordinates from CSD, after Williams et al., 2000.

### 1.5 Functional Applications of Metal-Organic Hybrid Framework

## Materials

In comparison to the enormous number of commercial applications of the aluminosilicate zeolites, hybrids offer certain advantages because of (i) the relative ease with which they can be functionalized, post-synthesis, (ii) the simplicity with which the pore size can be tuned over a wide range of sizes, and (iii) the manner in which enatiomerically-pure chiral frameworks can be created (Cheetham et al., 2004). Many interesting new hybrid materials have already been recently prepared with remarkable properties. These functional hybrids are considered as innovative
advance materials and promising applications, are expected in many fields (GómezRomero and Sánchez, 2004).

The practical usage standard for $\mathrm{H}_{2}$ storage of $6.5 \mathrm{wt} \%$ set by the $\mathrm{U} . \mathrm{S}$. Department of Energy at ambient temperature and low pressure is a big challenge and none of storage materials, such as metal hydrides, zeolites, and activated carbon adsorbents can meet such criterion. MOFs have some advantages on pore designable and large surface area over zeolites. They have been recently considered as the most hopeful hydrogen storage adsorbents. But the effectiveness of MOFs materials in hydrogen adsorption has mainly focused on the low temperature and the high pressure. Yaghi and co-workers have been recently synthesized and studies gas absorptions of a number of MOFs (Yaghi et al., 2003). A most impressive example in this series is MOF-5, which is a very low-density material, and there is a good deal of data on the gas storage capacities, including hydrogen and methane (Li et al., 1999). The design and preparation of MOF materials used as the gas storage materials, at an ambient temperature, is currently investigated by several research groups (Peterson et al., 2006; Kubas, 2007; Lin et al., 2007; Collins et al., 2008; Suh et al., 2008).

Porous, homochiral MOFs and their application in the heterogeneous asymmetric catalysis with the activity and the stereoselectivity rivalling their homogeneous counterparts have been reported in the recent literature (Soo et al., 2000; Wu et al., 2005; Dybtsev et al., 2006; Wu and Lin, 2007). Catalysis using organically pillared zirconium phosphate/phosphonate catalysts has also recently been reviewed by Clearfield and Wang (2002).

The exploitation of chemical functionalization within coordination framework structures has been reviewed (Decurtins et al., 1999; Maspoch et al., 2003; Kitagawa
et al., 2004; Murray and Kepert, 2004). One of the impressive examples of multifunctional material exhibiting both porosity and guest-responsive magnetic properties is $\left[\mathrm{Cu}_{3}(\mathrm{PTMTC})_{2}(\text { pyridine })_{6}(\mathrm{EtOH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]$, where PTMTC $=\operatorname{tris}(4-$ carboxylato-2,3,5,6-tetrachlorophenyl)methane (Maspoch et al., 2003). The inclusion of the ethanol guest species is accompanied by a breathing of the structure that significantly influences the magnetic properties of the framework which behaved similar to that found in $\left[\mathrm{Fe}_{2}(\text { azpy })_{4}(\mathrm{NCS})_{4}\right] \cdot$ guest (Halder et al., 2003). In addition, the optical properties of hybrid frameworks are also of considerable interest (Lacroix et al., 2001; Thushari et al., 2005; Bidault et al., 2006; Li et al., 2006).

As already mentioned, hybrid organic-inorganic materials are ubiquitous materials possessing the extensive compositional range, structural diversity, and many potential applications. Therefore, these materials are an interesting target for the present research project.

### 1.6 The Present Study

This study was carried out at the School of Chemistry, Suranaree University of Technology, Thailand (Chapter VII), School of Chemistry, Monash University, Australia (Chapters II-VI), Department of Chemistry, Hong Kong University of Science and Technology, Hong Kong (Chapter VII), and the Research School of Chemistry, The Australian National University, Canberra, Australia (Chapter VII).

The study at the School of Chemistry, Monash University, was the primary focus of the projects with the aim of using the principles of crystal engineering to synthesize, for the first time, 1-D tube-like motifs of cyanide-bridged bimetallic coordination polymers. Making comparisons to 2- and 3-D Prussian blue analogues
were important. A more general aim was to study the structural diversity and magnetic properties of cyanide-bridgeds bimetallic compounds that formed from the attempts to make the 1-D tubes. In attempts to synthesize the 1-D tube motifs, the complexes of formulae $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]$ and $\left[\mathrm{M}^{\prime}\left(\mathrm{L}^{\prime}\right)(\text { solvent })_{4}\right]$ (where $\mathrm{M}=\mathrm{Fe}^{\mathrm{II}}$ and $\mathrm{Fe}^{\mathrm{III}}$; $\mathrm{M}^{\prime}=$ first row transition metals; $\mathrm{L}=1,10$-phen, $2,2^{\prime}$-bipy, en, $\mathrm{tn} ; \mathrm{L}^{\prime}=\mathrm{en}, \mathrm{tn}$ ) were chosen as building blocks to form the tube motifs (Chapter III).

Other metallocyano and organocyano bridging groups were explored. For examples, a linear dicyanoargentate $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$was used as longer bridging ligand to replace the CN groups of the $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]^{2-}$ building block (Chapter III). The ideal candidate for this study was also expected to produce 1-D tube-like motifs of $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ bridged bimetallic coordination polymers. Other new supramolecular complexes involving the $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$groups could also form their structures by
 complex" of square planar tetracyanonickelate, $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$, was also employed as a building block for the construction of supramolecular coordination polymers (Chapter V).

The 2-connecting organodinitrile ligand, ACCN and AIBN, were used as bridging ligands for investigations of self-assembly processes in the construction of 3-D Fe(II) coordination polymer compounds, for which early reports in the AIBN compound (Zuur et al., 1981) had suggested they would exhibit thermally induced SCO behaviour. The structure and SCO magnetic properties of the $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{L})_{3}\right]\left(\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right)_{2}$ materials, where $\mathrm{L}=\mathrm{ACCN}$ or $\mathrm{AIBN}, \mathrm{M}^{\mathrm{III}}=\mathrm{Fe}$, In, are described here (Chapter VI).

In order to obtain information at the basic structural level as well as try to understand the details of the self-assembly process, which should be of general
interest for the crystal engineering of novel supramolecular metal coordination polymers, the covalent and noncovalent interactions of 3,6-bis(2'-pyrimidyl)-1,2,4,5tetrazine (bmtz) and 3,6-bis(2-pyridyl)-1,2,4,5-tetrazine (bptz) were investigated upon reaction with $\mathrm{Ag}(\mathrm{I})$ ion (Chapter II).

The study on open framework, hybrid organic-inorganic vanadium oxides (analogs of zeolite) was carried out at SUT, HKUST, and ANU. The aim was to use the aromatic diamine planar geometry of imidazole and hydro/solvothermal syntheses to introduce inorganic metal sites. This molecule is different from the aliphatic diamines previously used (Law et al., 2000; Law and Williams, 2000; Williams et al., 2000) in terms of basicity, size, shape, ligation ability, hydrogen bond capacity and charge, and this could allow different and more diverse framework structures. The framework structures were studied by single crystal X-ray analysis with physical techniques such as elemental analyses, XRD, EDX and TGA, used to support the structure analysis (Chapter VII).

The overarching themes of the project were to investigate metal coordination polymers of varying dimensionalities, with emphasis on synthesis, crystal growing, structural and magnetic properties. Cyanide-, metallocyanide- and organocyanobridging modes were of particular interest. Each chapter is designed to be selfcontained with its own relevant introduction, so the chapters need not be read sequentially. The introduction provides a general underpinning to the chemical, structural and magnetic aspects of the project.

## CHAPTER II

## SUPRAMOLECULAR

## ARCHITECTURE OF SILVER(I) COORDINATION POLYMERS CONTAINING MULTIMODAL LIGANDS

### 2.1 Introduction

One of the principal challenges of modern chemistry is that of the crystal engineering of new crystal structures with specific target properties (Sommerdijk, 2003; Tiekink and Vittal, 2006; Desiraju, 2007). In the context of coordination polymers, the combinations of coordinate covalent bonds and nocovalent interactions (eg. hydrogen bonds, $\pi-\pi$ stacking) have been employed in the construction of various dimensional supramolecular architectures (Batten, 2001; Batten and Murray, 2005; Holliday and Mirkin, 2001; Moulton and Zaworotko, 2001). Ideally, the overall topology of coordination polymers can be controlled by means of the coordination preferences of the metal center and the structure of the bridging ligand (Batten and Robson, 1998; Batten, 2005; Ockwig et al., 2005). However, in practice from many previous examples, solvent molecules or anion templates as well as the strength of noncovalent interactions were found to produce a dramatic effect on the extended structure of the network (Du et al., 2003; Dong et al., 2006; 2007). Therefore, it still requires the investigating and understanding the details of the assembly process of the coordination network.

Multidimensional coordination polymers based on $\operatorname{Ag}(\mathrm{I})$ and N -donor ligands are know in the literature (Khlobystov et al., 1991; Young and Hanton, 2008; Steel and Fitchett, 2008). To study types of intermolecular forces which may lead to new supramolecular architectures. The reaction of the multimodal ligands 3,6 -bis $\left(2^{\prime}\right.$-pyri-midyl)-1,2,4,5-tetrazine (bmtz), 1,4-dihydro-3,6-bis(2'-pyrimidyl)-1,2,4,5-tetrazine $\left(\mathrm{H}_{2} \mathrm{bmtz}\right)$ and 3,6-bis(2-pyridyl)-1,2,4,5-tetrazine (bptz), Scheme 1, are investigated with $\operatorname{Ag}(\mathrm{I})$ ions. The coordination sphere of $\operatorname{Ag}(\mathrm{I}), \mathrm{d}^{10}$ configuration, is very flexible and can adopt coordination numbers between two and six and various geometries from linear through trigonal to tetrahedral, trigonal pyramidal and octahedral (Venkataraman et al., 1997). The ligands are studied here not only have rich coordination modes with the capability of chelating metal ions, but are also able to form noncovalent interactions. It is anticipated that weak association of interactions such as $\mathrm{Ag} \cdots \mathrm{Ag}, \mathrm{Ag} \cdots \pi, \mathrm{C}-\mathrm{H}^{\cdots} \pi, \pi \cdots \pi$, and anion $\cdots \pi$ interactions will help to provide diversity to the architectures of the various dimensional coordination polymers formed. This study will advance our understanding of the development of supramolecular chemistry and the tuning and prediction of the crystal structures.

3,6-bis(2'-pyrimidyl)-1,2,4,5-tetrazine (bmtz)

1,4-dihydro-3,6-bis(2'-pyrimidyl)-1,2,4,5-tetrazine ( $\mathrm{H}_{2} \mathrm{bmtz}$ )

3,6-bis(2-pyridyl)-1,2,4,5-tetrazine

### 2.2 Experimental Section

### 2.2.1 Materials and Physical Measurements

The bmtz and $\mathrm{H}_{2}$ bmtz (Kaim and Fees, 1995), and bptz (Geldard and Lions, 1965) ligands were prepared following procedures reported previously. All chemicals were purchased from commercially available sources and were used without further purification.

Caution!: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of material should be prepared, and these should be handled with care. Reactions were performed under a fume hood.

Microanalytical measurements ( $\mathrm{C}, \mathrm{H}, \mathrm{N}$ ) were performed by Campbell Microanalytical Laboratory, Chemistry Department, University of Otago, Dunedin, New Zealand. Infrared spectra of Nujol mulls were recorded in the range on a Bruker Opus/IR IFS 55 spectrometer in the range of $600-4000 \mathrm{~cm}^{-1}$ ( 50 scans, resolution $\pm 4$ $\left.\mathrm{cm}^{-1}\right]$.

### 2.2.2 Syntheses

## Preparation of $\mathbf{A g}(\mathbf{t c m})$

$\mathrm{Ag}(\mathrm{tcm})$ was prepared by a literature procedure (Konnert and Britton, 1966). Typically, $\mathrm{AgNO}_{3}(3.40 \mathrm{~g}, 0.20 \mathrm{~mol})$ in $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$ was added to a solution of $\mathrm{K}(\mathrm{tcm})(2.55 \mathrm{~g}, 0.20 \mathrm{~mol})$ in $\mathrm{H}_{2} \mathrm{O}(20 \mathrm{~mL})$. After the mixture had been stirred for 30 minutes, an amorphous white powder was filtered off and dried at room temperature ( $3.70 \mathrm{~g}, 86 \%$ yield).

## Preparation of $\left[\mathrm{Ag}_{2}(\mathrm{bmtz})\left(\mathrm{ClO}_{4}\right)\right] \mathrm{ClO}_{4}(2 \mathrm{a})$

$\mathrm{AgClO}_{4}(82.7 \mathrm{mg}, 0.4 \mathrm{mmol})$ was dissolved in $1 \mathrm{~mL} \mathrm{MeNO}_{2}$ and pipetted into one side of a H-shaped tube. bmtz ( $23.7 \mathrm{mg}, 0.1 \mathrm{mmol}$ ) was dissolved in 2 mL of
$\mathrm{MeNO}_{2}$ and pipetted into the other side. The H -shaped tube was then carefully filled with $\mathrm{MeNO}_{2}$. The solutions were allowed to slowly diffuse into each other, and darkgreen block X-ray quality single crystals of 2a were obtained after 2 weeks. Yield: $11.0 \mathrm{mg}, 45 \%$ based on bmtz. Anal. Found (calcd) for $\mathrm{C}_{10} \mathrm{H}_{6} \mathrm{Ag}_{2} \mathrm{Cl}_{2} \mathrm{~N}_{8} \mathrm{O}_{8}(M r=$ $652.87 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 18.32(18.40), \mathrm{H}, 1.01(0.93), \mathrm{N}, 17.11(17.17)$. ATR-FTIR ( $v_{\max } /$ $\left.\mathrm{cm}^{-1}\right): 617 \mathrm{~m}, ~ 647 \mathrm{w}, 754 \mathrm{~m}, 793 \mathrm{w}, 822 \mathrm{w}, 923 \mathrm{w}, 954 \mathrm{w}, 1030 \mathrm{w}, 1082 \mathrm{w}, 1179 \mathrm{~m}, 1381 \mathrm{~s}$, 1441w, 1565w, 1581s, 1983w, 2166m, 2235w, 2324w, 3101w.

## Preparation of $[\mathrm{Ag}(\mathrm{bmtz})] \mathrm{ClO}_{4} \cdot \mathrm{MeCN}(2 b)$

$\mathrm{AgClO}_{4}(83.1 \mathrm{mg}, 0.4 \mathrm{mmol})$ was dissolved in 1 mL MeCN and pipetted into one side of a H-shaped tube. bmtz ( $24.1 \mathrm{mg}, 0.1 \mathrm{mmol}$ ) was dissolved in 2 mL of MeCN and pipetted into the other side. The H-shaped tube was then carefully filled with MeCN . The solutions were allowed to slowly diffuse into each other, and emerald-green column X-ray quality single crystals of $\mathbf{2 b}$ were obtained after 2 weeks. Yield: $17.0 \mathrm{mg}, 70 \%$ based on bmtz. Anal. Found (calcd) for $\mathrm{C}_{12} \mathrm{H}_{9} \mathrm{AgClN}_{9} \mathrm{O}_{4}$ $(M r=486.60 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 29.58(29.62), \mathrm{H}, 1.80(1.86), \mathrm{N}, 25.89(25.91)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 619 \mathrm{~m}, ~ 652 \mathrm{w}, 744 \mathrm{~m}, 802 \mathrm{w}, 815 \mathrm{w}, 978 \mathrm{w}, 999 \mathrm{w}, 1041 \mathrm{w}, 1095 \mathrm{w}, 1199 \mathrm{w}$, 1401s, 1441w, 1582w, 1593s, 1967w, 2171m, 2435w, 2504w.

## Preparation of $\left[\{\mathrm{Ag}(\mathrm{tcm})\}_{2}\left(\mathrm{H}_{2} \mathrm{bmtz}\right)(\mathrm{MeCN})\right](2 \mathrm{c})$

A hot solution of $\mathrm{Ag}(\mathrm{tcm})(371.7 \mathrm{mg}, 2 \mathrm{mmol})$ in 10 mL MeCN was added dropwise to a hot solution of the $\mathrm{H}_{2} \mathrm{bmtz}$ ligand ( $276.3 \mathrm{mg}, 1 \mathrm{mmol}$ ) in 10 mL MeCN with stirring to give an orange solution and left to stand at room temperature. After two days, orange-yellow block single crystals of 2c suitable for structure determination were obtained. Yield: $248.0 \mathrm{mg}, 90 \%$ based on $\mathrm{H}_{2}$ bmtz. Anal. Found (calcd) for $\mathrm{C}_{20} \mathrm{H}_{11} \mathrm{Ag}_{2} \mathrm{~N}_{15}\left(M_{r}=677.18 \mathrm{~g} / \mathrm{mol}\right): \mathrm{C}, 35.59(35.47), \mathrm{H}, 1.66(1.64), \mathrm{N}$,
31.14(31.03). ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 638 \mathrm{w}, 660 \mathrm{w}, 805 \mathrm{w}, 1004 \mathrm{w}, 1118 \mathrm{w}, 1242 \mathrm{w}$, 1279w, 1385m, 1438m, 1561m, 1635w, 2162s, 2234w, 3236w.

## Preparation of [\{Ag(tcm) $\left.\}_{2} \mathbf{b m t z}\right](2 d)$

A hot solution of $\mathrm{Ag}(\mathrm{tcm})(372.1 \mathrm{mg}, 2 \mathrm{mmol})$ in 10 mL MeCN was added dropwise to a solution of the bmtz ligand ( $238.1 \mathrm{mg}, 1 \mathrm{mmol}$ ) in 10 mL MeCN with stirring to give a red solution and left to stand at room temperature. After two days, orange-red block single crystals of 2d suitable for structure determination were obtained. Yield: 219.0 mg , $92 \%$ based on bmtz. Anal. Found (calcd) for $\mathrm{C}_{18} \mathrm{H}_{6} \mathrm{Ag}_{2} \mathrm{~N}_{14}$ $(M r=634.11 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 34.37(34.09), \mathrm{H}, 1.00(0.95), \mathrm{N}, 31.11(30.93)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 669 \mathrm{w}, 959 \mathrm{w}, 1019 \mathrm{~m}, 1070 \mathrm{w}, 1095 \mathrm{w}, 1317 \mathrm{w}, 1395 \mathrm{w}, 1452 \mathrm{w}, 1597 \mathrm{~s}$, $1982 \mathrm{w}, 2163 \mathrm{~s}, 2324 \mathrm{w}, 2867 \mathrm{w}, 2908 \mathrm{w}, 2960 \mathrm{w}, 3189 \mathrm{w}, 3285 \mathrm{~m}, 3340 \mathrm{~m}, 3580 \mathrm{~m}$, 3857s.

## Preparation of $\left[\mathrm{Ag}(\mathrm{bptz})\left(\mathrm{NO}_{3}\right)\right]$ (2e)

$\mathrm{AgNO}_{3}(34.0 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 1 mL MeCN and pipetted into one side of a H-shaped tube. bptz ( $47.5 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) was dissolved in 2 mL of MeCN and pipetted into the other side. The H-shaped tube was then carefully filled with MeCN . The solutions were allowed to slowly diffuse into each other at $4^{\circ} \mathrm{C}$, and the red plate X-ray quality single crystals of $\mathbf{2 e}$ were obtained after 2 days. Yield: 34.2 $\mathrm{mg}, 72 \%$ based on bptz. Anal. Found (calcd) for $\mathrm{C}_{12} \mathrm{H}_{8} \mathrm{AgN}_{7} \mathrm{O}_{3}(\mathrm{Mr}=406.11 \mathrm{~g} / \mathrm{mol})$ : C, $35.48(35.50), \mathrm{H}, 1.87(1.99), \mathrm{N}, 24.10(24.14)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 623 \mathrm{~m}, 644 \mathrm{w}$, $703 \mathrm{~m}, 726 \mathrm{w}, 733 \mathrm{w}, ~ 912 \mathrm{w}, ~ 944 \mathrm{w}, 1189 \mathrm{w}, 1352 \mathrm{w}, 1501 \mathrm{~m}, 1589 \mathrm{~s}, 1677 \mathrm{w}, 1965 \mathrm{w}$, 1991w, 2104m, 2335w, 2584w, 3231w.

## Preparation of $\left[\mathrm{H}_{2} \mathrm{bptz}\right]\left(\mathrm{NO}_{3}\right)_{2}(\mathbf{2 f})$

$\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}(81.2 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 1 mL of MeCN and pipetted into one side of a H-shaped tube. bptz ( $47.1 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) was dissolved in 2 mL of MeCN and pipetted into the other side. The H-shaped tube was then carefully filled with MeCN. The solutions were allowed to slowly diffuse into each other at 4 ${ }^{\circ} \mathrm{C}$, and the red plate X-ray quality single crystals of 2 f were obtained after 3 days. Yield: $14.2 \mathrm{~g}, 30 \%$ based on bptz. Anal. Found (calcd) for $\mathrm{C}_{24} \mathrm{H}_{20} \mathrm{~N}_{16} \mathrm{O}_{12}$ ( $\mathrm{Mr}=$ $724.56 \mathrm{~g} / \mathrm{mol}$ ): C, $39.81(39.79), \mathrm{H}, 2.73(2.78), \mathrm{N}, 25.89(25.02)$. ATR-FTIR ( $v_{\max } /$ $\left.\mathrm{cm}^{-1}\right): 623 \mathrm{~m}, ~ 639 \mathrm{w}, ~ 678 \mathrm{~m}, 705 \mathrm{w}, 814 \mathrm{w}, 889 \mathrm{w}, 934 \mathrm{w}, 1010 \mathrm{w}, 1139 \mathrm{w}, 1365 \mathrm{~m}, 1465 \mathrm{~s}$, 1784w, 2324w, 3241w.

### 2.2.3 X-Ray Crystallographic Study

Single crystals of 2a-2f were mounted on a MiTeGen MicroMounts fiber in a small amount of oil prior to measurements made by Dr. Suzanne M. Neville and Dr. Craig Forsyth, Monash University. Reflection intensities were collected on a Bruker X8 APEX CCD diffractometer (Mo $K_{\alpha}$ radiation, $\bar{\lambda}=0.71073 \AA$ ) and equipped with an Oxford Instruments nitrogen gas Cryostream. Empirical absorption corrections were applied to all data using SADABS (Blessing, 1995). The structures were solved using SHELXS-97 (Sheldrick, 1997) and refined on $F^{2}$ using SHELXL-97 (Sheldrick, 1997) with X-SEED (Barbour, 2001) as a graphical interface.

In the final cycles of refinement, all atoms except hydrogen atoms were refined anisotropically. All hydrogen atoms were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C} / \mathrm{N}-\mathrm{H}$ distances in the range 0.95 to $0.99 \AA$, with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C}, \mathrm{N})\left[1.5 U_{\text {eq }}(\mathrm{C})\right.$ for methyl hydrogen atoms $]$. For compounds $2 \mathbf{a}$ and $\mathbf{2 b}$ the $\left[\mathrm{ClO}_{4}\right]^{-}$anions were found to be disordered, and were
modeled in two different orientations. The total occupancy of both orientations was fixed to one. Crystal data and details of the data collection and structure refinement for compounds 2a-2f are summarized in Table 2.1. Selected interatomic bond lengths and angles for compounds $\mathbf{2 a} \mathbf{- 2 b}, \mathbf{2 c} \mathbf{- 2 d}$ and $\mathbf{2 e}$ are given in Tables 2.2, 2.3, and 2.4, respectively. The bond lengths and angles and other crystallographic data are given as supplementary material in the CIF which can be found on the attached CD-ROM.

Table 2.1 Summary of crystallographic data for the compounds 2a-2f.

### 2.3 Results and Discussion

### 2.3.1 1-D Ribbons Structure of $\left[\mathrm{Ag}_{2}(\mathrm{bmtz})\left(\mathrm{ClO}_{4}\right)\right] \mathrm{ClO}_{4}(2 \mathrm{a})$

The complex 2a was prepared as deep green blocks from the $4: 1$ reaction of $\mathrm{AgClO}_{4}$ and the bmtz ligand in $\mathrm{MeNO}_{2}$ solution at room temperature. Attempts to grow single crystals by change of counter anions from $\mathrm{AgClO}_{4}$ to $\mathrm{AgBF}_{4}$ and $\mathrm{AgSbF}_{6}$ using the same procedure as in 2 a were unsuccessful. Figure 2.1 shows the asymmetric unit with atomic numbering and the detailed coordination environment for the $\operatorname{Ag}(\mathrm{I})$ ions. There are two types of crystallographically and chemically different $\mathrm{Ag}(\mathrm{I})$ ions. The Ag 1 center adopts a square pyramidal five coordinate geometry with four nitrogen atoms from two different bmtz ligands and one oxygen atom from a coordinated perchlorate counter ion in axial position. The geometry is evaluated by the parameter, $\tau=(\alpha-\beta) / 60$, where $\alpha$ and $\beta$ are the angles between the nitrogen donor atoms forming the basal plane in square pyramidal geometry. For ideal square pyramidal and trigonal bipyramidal geometry $\tau$ is equal to 0 and 1, respectively (Addison et al., 1984). The calculated values of the $\tau$ parameter for the Ag 1 ion is equal to 0 , indicating that Ag 1 geometry in $2 \mathbf{a}$ is perfectly square pyramidal. The Ag2 center has a five coordinate geometry formed by four nitrogen donor of two different bmtz ligands and an oxygen of a perchlorate counter ion in the axial position. However, Ag2 also weakly bonded by another oxygen atom from a different perchlorate counter ion to give a pseudo trigonal prismatic arrangement.

The $\mathrm{Ag}-\mathrm{N}$ bond lengths range from $2.328(8)$ to $2.529(5) \AA$. This range is comparable to that found in the square-pyramidal geometry of $\left[\mathrm{Ag}_{2}(\mathrm{bptz})_{2}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{2}\right]$ $\left[\mathrm{PF}_{6}\right]_{2}$ (Schottel et al., 2006). The $\mathrm{Ag}-\mathrm{O}$ bond lengths are 2.328(1) and 2.521(10) $\AA$ for $\mathrm{Ag} 1-\mathrm{O} 1$ and $\mathrm{Ag} 2-\mathrm{O} 2$, respectively. These values are shorter than the mean value

(a)

(b)

Figure 2.1 (a) Thermal ellipsoid plot of a fragment at the $50 \%$ probability level containing the asymmetric unit with atom numbering and (b) coordination environments of the metal ceters of $2 \mathbf{2 a}$. The labeling scheme, $A$ and $B$, applied for the phenyl rings are used to identity the rings in subsequent discussion. Symmetry codes: (i) $-x,-0.5+y,-z$; (ii) $-x, 0.5+y,-z$.

Figure 2.2 (a) Packing diagram for 2a viewed down the $c$ axis and showing anion $\cdots \pi$ and $\mathrm{Ag} \cdots \pi$ interactions and (b) the shortest contacts between perchlorate anions and the pyrimidine or tetrazine rings and Ag ions.
of $2.53 \AA$ for $\mathrm{Ag}-\mathrm{O}\left(\mathrm{ClO}_{3}^{-}\right)$from 370 datasets with 752 occurrences obtained from the CSD (Allen et al., 1991). The Ag2 $\cdots$ O5 bond length is $2.667(6) \AA$. This value is considered to be a weak interaction and not a formal $\mathrm{Ag}-\mathrm{O}$ bond (Young and Hanton, 2008). The values of the intra ligand $\mathrm{N}-\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ bond distances have typical values, and are in agreement with those reported for the free bmtz molecule (Glöckle et al., 2001). The pyrimidine and the tetrazine rings of the bmtz ligand are planar, but the ligand as a whole is not. The mean deviation (r. m. s. deviation of fitted atoms) from the best plane calculated using eighteen atoms is $0.046 \AA$ with the largest deviation being $0.091(4) \AA$ at N 2 . Each bmtz molecule is bis-chelating to two $\mathrm{Ag}(\mathrm{I})$ ions in the syn orientation. The $\mathrm{Ag} \cdots \mathrm{Ag}$ separation along the length of the bmtz ligands is $4.289(1) \AA$. The $\mathrm{Ag} \cdots \mathrm{Ag}$ separations across the bridging bmtz ligands range from 6.378 (1) to $7.757(1) ~ \AA$ (Table 2.2).

The structure of $2 \mathbf{2 a}$ consists of $1-\mathrm{D}[\mathrm{Ag}(\mathrm{bmtz})]^{+}$cation ribbons running parallel to the crystallographic $b$ axis, and the perchlorate counter anions lie between the cationic chains. The self-assembly of the supramolecular coordination polymers in 2a is the result of combinations of forces including strong silver-bmtz coordination bonds (Table 2.2) and weak interactions of intermolecular anion $\cdots \pi, \mathrm{C}-\mathrm{H} \cdots \mathrm{O}, \mathrm{C}-\mathrm{H} \cdots \pi$ hydrogen bonds and $\pi-\pi$ stacking (Tables 2.6-2.8). These interactions help to stabilize the assembly as well as increase the dimensionality of the structure.

Along the crystallographic $c$ axis, each ribbon is connected to two adjacent ribbons via anion $\cdots \pi, \mathrm{Ag} \cdots \mathrm{N}$, ef $\mathrm{C}-\mathrm{H}^{\cdots} \pi$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions. Each anion interacts with the centroid $\left(C_{g}\right)$ of a pyrimidine or tetrazine ring with the $\mathrm{O} \cdots C_{g(\text { pyrimidine })} / C_{g \text { (tetrazine) }}$ ranging from $2.882(8)$ to $3.151(20) \AA$. The $\mathrm{Ag} \cdots \mathrm{O}$ distances of $2.667(6)$ [Ag2 $\cdots \mathrm{O} 5(1 / 2+x, 1 / 2-y, 1 / 2-z)$ ] and 3.174(6) $\AA[\mathrm{Ag} 2 \cdots \mathrm{O} 7$ ] are
significantly shorter the sum of the van der Waals radii of Ag and O, $3.22 \AA$ (Bondi, 1964), indicating the existence of $\mathrm{Ag} \cdots \mathrm{O}$ interactions, Figure 2.2. One feature of $\mathbf{2 a}$ is the formation of ef $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions. Hydrogen atoms, H 2 , of the stacked pyrimidine rings point towards the $C_{g}$ faces of pyrimidine rings of $\mathrm{N} 1 / \mathrm{N} 2 / \mathrm{C} 1 / \mathrm{C} 2 / \mathrm{C} 3 / \mathrm{C} 4\left(\right.$ ring $A$ ) at distance $3.192(9) \AA$ with dihedral angle of $39.4(9)^{\circ}$, Figure 2.3.

Figure 2.3 Space-filling representations for 2a project slightly onto $a b$ plane showing ef $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions.

The shortest $\mathrm{C} \cdots \mathrm{C}$ distance between the pyrimidine rings (ring $A$ ) of the $[\mathrm{Ag}(\mathrm{bmtz})]^{+}$moiety is $3.325(9) \AA$ at C 1 , indicating the presence of weak offset $\pi \cdots \pi$ interactions (Desiraju and Steiner, 1999), Figure 2.4. Further investigation of the packing structure showed that the assembly of the 1-D ribbons of 2 a into a 3-D supramolecular architecture is accomplished via additional $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds involving the anions and the bmtz ligands.

Figure 2.4 Packing diagram for 2a showing weak $\pi \cdots \pi$ interactions.

${ }^{a}$ Estimated standard deviations of the least significant digits are given in parentheses.
2a: ring $A=\mathrm{N} 1 / \mathrm{N} 2 / \mathrm{C} 1 / \mathrm{C} 2 / \mathrm{C} 3 / \mathrm{C} 4$; ring $B=\mathrm{N} 1^{1} / \mathrm{N} 2 / \mathrm{N} 3{ }^{\mathrm{i}} / \mathrm{N} 4 / \mathrm{C} 5 / \mathrm{C} 5^{\mathrm{i}}$. 2b: ring $D=$ $\mathrm{N} 2 / \mathrm{N} 2{ }^{\mathrm{ii}} / \mathrm{N} 4 / \mathrm{N} 4{ }^{\mathrm{ii}} / \mathrm{C} 5 / \mathrm{C} 5^{\mathrm{ii}}$; ring $F=\mathrm{N} 5 / \mathrm{N} 5{ }^{\mathrm{ii}} / \mathrm{N} 7 / \mathrm{N} 77^{\mathrm{ii}} / \mathrm{C} 10 / \mathrm{C} 10^{\mathrm{ii}} . C_{g}$ is centroid of a ring. Symmetry codes: (i) $-x,-y,-z$; (ii) $x, 1 / 2-y, z$.

### 2.3.2 1-D Chain Structure of $[\mathrm{Ag}(\mathrm{bmtz})] \mathrm{ClO}_{4} \cdot \mathrm{MeCN}(2 \mathrm{~b})$

Using the same stoichiometric ratio of the metal and ligand as in 2a, but with the diffusion solvent changed from $\mathrm{MeNO}_{2}$ to MeCN , emerald-green column-shaped crystals of $\mathbf{2 b}$ were obtained in high yield. Attempts to grow single crystals by change of counter ions from $\mathrm{AgClO}_{4}$ to $\mathrm{AgBF}_{4}, \mathrm{AgCF}_{3} \mathrm{SO}_{3}, \mathrm{AgNO}_{3}$ and $\mathrm{AgSbF}_{6}$ were unsuccessful.

Figure 2.5 Thermal ellipsoid plot of a fragment of $\mathbf{2 b}$ at the $50 \%$ probability level containing its asymmetric unit with atom numbering and showing coordination environments of metals ceter. The two orientations of the disordered of perchlorate are shown in different colors. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $C-F$, applied for the phenyl rings are used to identity the rings in the subsequent discussion. Symmetry codes: (i) $x, 0.5-y, z$; (ii) $0.5+x, y$, $0.5-z$.

The single crystal X-ray determination of $\mathbf{2 b}$ revealed that MeCN solvent is present in the structure. The asymmetric unit consists of one $\mathrm{Ag}(\mathrm{I})$ cation, two half of a bmtz ligand, one perchlorate counter anion, and one solvent MeCN molecule. Each $\mathrm{Ag}(\mathrm{I})$ ion adopts a six-coordinate geometry with six nitrogen atoms from three bmtz moieties in a trigonal prismatic arrangement as shown in Figure 2.5. The $\mathrm{Ag} \cdots \mathrm{Ag}(x$, $0.5-y, z$ ) separation along the bmtz ligand is $4.284(1) \AA$. The $\mathrm{Ag}-\mathrm{N}$ distances are in the range $2.440(7)$ to $2.583(7) \AA$, comparable to that observed in $\left[\mathrm{Ag}_{2}(\mathrm{bptz})_{3}\right]\left[\mathrm{SbF}_{6}\right]_{2}$ (Schottel et al., 2006). The bond lengths and angles of the bmtz molecule in $\mathbf{2 b}$ are also comparable to those in 2a.

Figure 2.6 1-D chain propagating along the $a$ axis in $\mathbf{2 b}$. The MeCN solvent and disordered counter ions are represented in space filling mode, and are located between the chains. Hydrogen atoms are omitted for clarity.

A view depicting the solid state packing in $\mathbf{2 b}$ is shown in Figure 2.6. The structure has 1-D ladder ribbons running parallel to the crystallographic $a$ axis. The $\left[\mathrm{ClO}_{4}\right]$ counter ions and solvent MeCN molecules lie between the ribbons and establish intermolecular interactions which cross-link the neighboring ribbons via anion $\cdots \pi, \mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \pi$ hydrogen bonds. As illustrated in Figure 2.7, the perchlorate $(\mathrm{Cl} 1)$ anion interacts with three a tetrazine rings (rings $D$ and $F$ ). Each oxygen atom of the $\left[\mathrm{ClO}_{4}\right]$ counter anions is oriented toward the $C_{g}$ of tetrazine ring with the $\mathrm{O} \cdots C_{g}$ distances in the range 2.895 to $2.967 \AA$. Further investigation of the packing structure found that the distance of $\mathrm{O} 5 \mathrm{~b} \cdots C_{g}(\operatorname{ring} D)$ is $3.103 \AA$, which indicating the existence of anion $\cdots \pi$ interactions (Hoog et al., 2004) between the ribbons, Figure 2.7b.

Figure 2.7 The shortest contacts in $\mathbf{2 b}$.

Furthermore, the pyrimidine moiety of the bmtz ligand is in close proximity to a neighbouring $\left[\mathrm{ClO}_{4}\right]$ anions (which lie on mirror planes) with the $\mathrm{C} \cdots \mathrm{O}$ distances ranging from $2.918(17)$ to $3.179(15) \AA$, indicating the existence of weak hydrogen bonds (Desiraju and Steiner, 1999). Additionally, the hydrogen atoms of the MeCN solvent molecules act as hydrogen bonds donor towards $C_{g}$ of pyrimidine rings of bmtz moieties (rings $C$ and $D$ ) to form $\mathrm{C}-\mathrm{H}^{\cdots} \pi$ interactions.

Figure 2.8 Packing in $\mathbf{2 b}$ along the $a$ axis showing the $\pi-\pi$ stacking interactions between pyrimidine rings. $\left[\mathrm{ClO}_{4}\right]$ counter ions, MeCN molecules, and hydrogen atoms are omitted for clarity.

Unlike the complex 2a, in which each $\operatorname{Ag}(\mathrm{I})$ is coordinated by two bmtz moieties, $\mathbf{2 b}$ adopts a tris-chelate $\operatorname{Ag}(\mathrm{I})$ environment. There are significant weak $\pi-\pi$ intermolecular interactions between the pyrimidine rings of bmtz ligands from neighboring chains which are almost parallel to each other, with a $C_{g} \cdots C_{g}$ distance of $4.084 \AA$. Interestingly, the coexistence of $\mathrm{a}[\mathrm{Ag}(\mathrm{bmtz})]$ coordination network with the intermolecular $\pi-\pi$ stacking results in a highly symmetric arrangement of the 3-D supramolecular architecture as shown in Figures 2.8 and 2.9.

Figure 2.9 Perspective views of $\mathbf{2 b}$ along the crystallographic $a$ axis. $\left[\mathrm{ClO}_{4}\right]$ counter ions, MeCN molecules, and hydrogen atoms are omitted for clarity.

### 2.3.3 1-D Chain Structure of $\left[\{\mathrm{Ag}(\mathrm{tcm})\}_{2}\left(\mathrm{H}_{2} \mathrm{bmtz}\right)(\mathrm{MeCN})\right](2 \mathrm{c})$

A 1-D coordination polymer is formed by the $2: 1$ reaction of $\mathrm{Ag}(\mathrm{tcm})$ and $\mathrm{H}_{2}$ bmtz in MeCN solution, and subsequent solvent evaporation at ambient temperature. The asymmetric unit contains two $\mathrm{Ag}(\mathrm{I})$, two tcm, one $\mathrm{H}_{2} \mathrm{bmtz}$, and one MeCN molecule as shown in Figure 2.10. The 1-D polymeric chains contain two unique $\operatorname{Ag}(\mathrm{I})$ ions. One $\mathrm{Ag}(\mathrm{I})$ atom has a distorted tetrahedral coordination, with two bonds to two nitrogen atoms from the $\mathrm{H}_{2}$ bmtz ligand and to two nitrogen atoms from the tcm ligand. The silver atoms have relatively long bonds to $\mathrm{H}_{2}$ bmtz and short bonds to tcm ligands. The $\mathrm{Ag}-\mathrm{N}$ distances are 2.491(4), 2.364(4), 2.230(3), and 2.294(4) $\AA$ for $\mathrm{Ag} 1-\mathrm{N} 1, \mathrm{Ag} 1-\mathrm{N} 2, \mathrm{Ag} 1-\mathrm{N} 9$, and $\mathrm{Ag} 1-\mathrm{N} 10$, respectively.

Figure 2.10 Thermal ellipsoid plot of a fragment of 2c at the $50 \%$ probability level containing its asymmetric unit with atom numbering. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $G-I$, applied for the phenyl rings are used to identify the rings in subsequent discussion. Symmetry codes: (i) $-x,-0.5+y,-z$; (ii) $-x, 0.5+y,-z$.

These $\mathrm{Ag}-\mathrm{N}$ bond distances are comparable to those found in the $\operatorname{Ag}(\mathrm{I})$ containing aromatic N -donor and tcm ligands complexes such as $\left[\mathrm{Ag}(\mathrm{tcm})(\mathrm{phz})_{1 / 2}\right]$ and $[\mathrm{Ag}(\mathrm{tcm})(\mathrm{pyz})]$ (Batten et al., 1998). The $\mathrm{N}-\mathrm{Ag}-\mathrm{N}$ bond angles range from 103.7(1) to $108.3(1)^{\circ}$. The $\mathrm{H}_{2} \mathrm{bmtz}$ ligand exhibits an acute $\mathrm{N} \cdots \mathrm{N}$ bite distance of $2.735(6) \AA[\mathrm{N} 1 \cdots \mathrm{~N} 2]$. The bite angle of $\mathrm{H}_{2} \mathrm{bmtz}$ is $68.5(1)^{\circ}$ for $\mathrm{N} 1-\mathrm{Ag} 1-\mathrm{N} 2$. As a result, the Ag 1 coordination sphere is distorted from ideal tetrahedral geometry. The ligand as a whole is not planar (r. m. s. $=0.488 \AA$ and the largest deviation $=0.916(4)$ $\AA$ at N4). Ag2 has distorted trigonal planar geometry, coordinating to two nitrogen atoms of $\mathrm{H}_{2} \mathrm{bmtz}$ ligands and one nitrogen atom of a tcm ligand. Again, the $\mathrm{Ag}-\mathrm{N}$ distances have relatively long bonds to the $\mathrm{H}_{2}$ bmtz ligand with 2.395(3) and 2.373(4) $\AA$ for $\mathrm{Ag} 2-\mathrm{N} 5$ and $\mathrm{Ag} 2-\mathrm{N} 7$, respectively, and a short bond to the tcm ligand at $2.174(4) \AA(\mathrm{Ag} 2-\mathrm{N} 12)$. There is a MeCN molecule which bonds weakly [Ag2 $\cdots \mathrm{N} 15$ $=2.629(5) \AA]$ in an axial position. The bond angles in the equatorial plane of $\operatorname{Ag}(\mathrm{I})$ differ considerably from the ideal trigonal angle of $120^{\circ}$, with two large angles of $152.6(1)^{\circ}(\mathrm{N} 5-\mathrm{Ag} 2-\mathrm{N} 12)$ and $137.5(1)^{\circ}(\mathrm{N} 7-\mathrm{Ag} 2-\mathrm{N} 12)$, and one small angle of $69.6(1)^{\circ}(\mathrm{N} 5-\mathrm{Ag} 2-\mathrm{N} 7)$. The $\Sigma_{\mathrm{Ag}}$ is $359.7^{\circ}\left(360^{\circ}\right.$ for ideal).

All tcm ions are very nearly trigonal planar, as was observed for the $\mathrm{K}(\mathrm{tcm})$ structures (Witt and Britton, 1971). As shown in Figure 2.11, the Ag1 ions are bridged by $\mu_{1,5}$ tcm anions (Batten and Murray, 2003) into 1-D chains. The Ag1 ceters of the chains are also coordinated to $\mathrm{H}_{2} \mathrm{bmtz}$ ligands, which in turn coordinate to Ag 2 ions. These Ag 2 ions are also coordinated to the MeCN molecules and to terminal $\mu_{1}$ tcm anions. As a result, pendant $\mathrm{Ag} 1-\mathrm{H}_{2} \mathrm{bmtz}-\mathrm{Ag} 2(\mathrm{tcm})(\mathrm{MeCN})$ 'arms' are created, which are attached to the $\operatorname{Ag} 1(\mathrm{tcm})$ chains. These chains are further connected into a 3-D network by weak $\mathrm{Ag} \cdots \mathrm{N}$ interactions between the uncoordinated nitrogen atoms
of the $\mu_{1} \mathrm{tcm}$ anions and the Ag atoms of adjacent chains $(\mathrm{Ag} 1 \cdots \mathrm{~N} 15=2.782(2) \AA$, $\mathrm{Ag} 2 \cdots \mathrm{~N} 16=2.816(2) \AA)$. Furthermore, supramolecular layers are formed by $\mathrm{Ag}-\pi$ ( $C_{g}$ ring $G$ ), $\pi-\pi$ stacking ( $C_{g}$ ring $I \cdots C_{g}$ ring $I$ ) and $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions as shown in Figures 2.11 and 2.12. All relevant interactions are listed in Tables 2.9-2.10.

### 2.3.4 2-D Sheets Structure of $\left[\{\mathrm{Ag}(\mathrm{tcm})\}_{2} \mathrm{bmtz}\right](2 d)$

Analogous to 2c, reaction of a 2:1 molar ratio of $\mathrm{Ag}(\mathrm{tcm})$ with bmtz in MeCN gave an orange-red polymer $\left[\{\operatorname{Ag}(\mathrm{tcm})\}_{2} \mathrm{bmtz}\right]$, 2d. The asymmetric unit consists of
one $\operatorname{Ag}(\mathrm{I})$, one tcm, and half a bmtz ligand as shown in Figure 2.13. The Ag and tcm moieties lie on general positions, however, the bmtz lies across an inversion ceter. No solvent molecules are present in the structure. The Ag atom exhibits a distorted square pyramidal $\mathrm{AgN}_{5}$ environment, the value of the trigonality parameter $\tau$ being 0.27 (Addison et al., 1984). The equatorial positions around the Ag atom are defined by four nitrogen atoms, two from the bmtz ligand (N1 and N2), and another two from a bridging tcm ( N 5 and N 7 ). The apical position is filled by a nitrogen atom of another tcm bridge (N6).

Figure 2.13 Thermal ellipsoid plot of a fragment of $\mathbf{2 d}$ at the $50 \%$ probability level containing the asymmetric unit with atom numbering and showing coordination environments of the metal ceter. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $K$ and $L$, applied to the phenyl rings are used to identity the rings in the subsequent discussion. Symmetry codes: (i) $-x,-0.5+y, 0.5-z$; (ii) $-x$, $0.5+y, 0.5-z$.

The two $\mathrm{Ag}-\mathrm{N}_{\text {bmtz }}$ bond distances are 2.332(4) and 2.627(4) $\AA$ for $\mathrm{Ag} 1-\mathrm{N} 1$ and Ag1-N2, respectively. These values are comparable to those observed in the related bis-chelate of the dptz-containing $\operatorname{Ag}(\mathrm{I})$ complex $[\mathrm{Ag}(\mathrm{bptz})]\left[\mathrm{PF}_{6}\right]$ (Schottel et al., 2006). The $\mathrm{Ag}-\mathrm{N}_{\text {tom }}$ bond distances vary in the range $2.337(4)$ to $2.461(4) \AA$. These observations are similar to those observed in $\left[\mathrm{Ag}(\mathrm{tcm})(\mathrm{phz})_{1 / 2}\right]$ and $[\mathrm{Ag}(\mathrm{tcm})(\mathrm{pyz})]$ (Batten et al., 1998). The bmtz ligand exhibits an usual acute $\mathrm{N} \cdots \mathrm{N}$ bite distance of $2.725(5) \AA[\mathrm{N} 1 \cdots \mathrm{~N} 2]$ with a bite angle of $66.3(1)^{\circ}[\mathrm{N} 1-\mathrm{Ag} 1-\mathrm{N} 2]$. The reduced bite of the bis-chelated bmtz ligand is the main source of distortion of the ideal square pyramidal environment of the $\operatorname{Ag}(\mathrm{I})$ atoms. The $\mathrm{N} 1 / \mathrm{N} 2 / \operatorname{Ag} 1 / \mathrm{N} 5 / \mathrm{N} 7$ set of atoms defines the basal plane, and the largest deviation from their mean plane is $0.352(1) \AA$ at Ag 1 , which is shifted from the mean basal plane toward the apical position. The $\mathrm{Ag} \cdots \mathrm{Ag}$ separations across bridging 1,2-bmtz and tcm ligands are $7.725(1) \AA[\operatorname{Ag} 1 \cdots \operatorname{Ag} 1(1-x, 1-y, 1-z)]$ and $7.601(1) \AA[\operatorname{Ag} 1 \cdots \operatorname{Ag} 1(-x, 0.5+y$, $0.5-z)$ ], respectively.

As shown in Figure 2.12, the structure of 2d contains distorted square pyramidal Ag atoms, which are coordinated to three tcm anions and one bmtz ligand. The tcm anions bridge in a tridentate $\mu-1,3,5$ fashion (Batten and Murray, 2003), which is similar to those observed in $\mathrm{M}(\mathrm{tcm})_{2}$, where $\mathrm{M}=\mathrm{Cr}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Cu}, \mathrm{Zn}$, Cd , or Hg (Batten et al., 1999), and connect the $\mathrm{Ag}(\mathrm{I})$ atoms into ladder-like motifs. These ladders are then cross-linked by the bridging bmtz ligands to generate a 2-D sheet as shown in Figure 2.14.

There are no $\pi-\pi$ interactions between adjacent bmtz rings. The shortest distance between $C_{g}$ to $C_{g}$ of pyrimidine rings of bmtz ligands is $5.773(7) \AA$, which is out the range (3.3-3.8 $\AA$ ) considered for significant $\pi \cdots \pi$ interactions (Janiak, 2000).

There are, however, weak $\mathrm{Ag} \cdots \pi$ interaction at $3.551(2) \AA$ between adjacent sheets. The sheets are further stacked along the crystallographic $b$ axis by weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds (Table 2.2) assembled to a 3-D supramolecular architecture.

### 2.3.5 1-D Chain Structure of $\left[\mathrm{Ag}(\mathrm{bptz})\left(\mathrm{NO}_{3}\right)\right]$ (2e)

The equivalent molar reaction of $\mathrm{AgNO}_{3}$ and bptz in MeCN gave dark red crystals of complex $\left[\mathrm{Ag}(\mathrm{bptz})\left(\mathrm{NO}_{3}\right)\right]$, 2e. Change of mole ratio of $\mathrm{Ag}(\mathrm{I})$ metal and bptz to 1:2 and 1:4 do not have any significant effect on the nature of the products, provided the reactant ratios of 1:1 remain the same as evidenced by single crystal Xray analysis. The unit cell parameters of a representative of those crystals were identical to the cell parameters in compound $\mathbf{2 e}$. Attempts to grow single crystals by change of counter anions from $\mathrm{AgNO}_{3}$ to $\mathrm{AgBF}_{4}, \mathrm{AgCF}_{3} \mathrm{SO}_{3}, \mathrm{AgClO}_{4}$, and $\mathrm{AgSbF}_{6}$ using the same procedure as in $\mathbf{2 e}$ were unsuccessful.

Figure 2.15 Thermal ellipsoid plot of a fragment of $\mathbf{2 e}$ at the $50 \%$ probability level containing its asymmetric unit with atom numbering. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $L-T$, applied to the phenyl rings are used to identity the rings in subsequent discussion. Symmetry code: (i) $2+x, y,-1+z$.

Compound $2 \mathbf{e}$ is isostructural with the analogous $\mathrm{PF}_{6}$ salt, $[\mathrm{Ag}(\mathrm{bptz})] \cdot \mathrm{PF}_{6}$ (Schottel et al., 2006). The asymmetric unit is shown in Figure 2.15, and consists of three $\mathrm{Ag}(\mathrm{I})$, each of which reside on an inversion center, three bptz ligands, and three
nitrate molecules. Each $\operatorname{Ag}(\mathrm{I})$ ion has the same environment. The $\operatorname{Ag}(\mathrm{I})$ ions exhibit a square pyramidal geometry with chelating bptz ligands forming the basal plane, and an oxygen atom belonging to a nitrate counter anions coordinated in the apical position.

The $\mathrm{Ag}-\mathrm{N}$ bond lengths range from $2.237(4)$ to $2.734(3) \AA$ and are comparable to those found in compounds $2 \mathbf{2 a}-\mathbf{2 b}$, and other related $\operatorname{Ag}(\mathrm{I})$ containing bptz complexes such as $\left[\mathrm{Ag}_{2}(\mathrm{bptz})_{3}\right]\left(\mathrm{AsF}_{6}\right)_{2}\left(\right.$ Schottel et al., 2005) and $[\mathrm{Ag}(\mathrm{bptz})] \cdot \mathrm{PF}_{6}$ (Schottel et al., 2006). The $\mathrm{Ag}-\mathrm{O}$ bond lengths range from 2.514(4) to 2.598(5) $\AA$, and are within the expected range and comparable to the calculated average value of $2.51 \AA$ from 370 datasets with 752 occurrences for $\mathrm{Ag}-\mathrm{O}\left(\mathrm{NO}_{2}\right)^{-}$obtained from the CSD (Allen et al., 1991). The bptz ligand exhibits acute $\mathrm{N} \cdots \mathrm{N}$ bite distances ranging from $2.716(6)$ to $2.824(6) \AA$ with bite angles of between $68.1(1)$ and $69.8(1)^{\circ}$. The axial $\mathrm{N}-\mathrm{Ag}-\mathrm{N}$ bond angles are $177.7(1)$ to $108.3(1)^{\circ}$. The calculated values of the $\tau$ parameter for $\mathrm{Ag} 1, \mathrm{Ag} 2$ and Ag 3 ions are $0.195,0.143$ and 0.123 , respectively, indicating that all geometries are close to square pyramidal. These indicate that the Ag coordination sphere is distorted from an ideal square pyramidal. The $\mathrm{Ag} \cdots \mathrm{Ag}$ separations across the bridging bptz ligands are $7.667(1)$ and $7.473(1)$ and $7.517(1) \AA$, for $\mathrm{Ag} 1 \cdots \mathrm{Ag} 2 \mathrm{Ag} 2 \cdots \mathrm{Ag} 3$ and $\mathrm{Ag} 1 \cdots \mathrm{Ag} 3(x-2, y, z+1)$, respectively. In addition, the bptz ligand as a whole is not planar. The mean deviation (r. m. s. deviation of fitted atoms) from the best plane calculated using eighteen atoms are $0.146,0.214$ and 0.282 $\AA$ for rings $\mathrm{L} / \mathrm{M} / \mathrm{N}, \mathrm{O} / \mathrm{P} / \mathrm{Q}$, and $\mathrm{R} / \mathrm{S} / \mathrm{T}$, respectively. The largest deviations are $-0.274(5)$ at $\mathrm{C} 10,-0.400(4)$ at C 15 and $-0.515(4) \AA$ at C 27 for rings $\mathrm{L} / \mathrm{M} / \mathrm{N}, \mathrm{O} / \mathrm{P} / \mathrm{Q}$, and $\mathrm{R} / \mathrm{S} / \mathrm{T}$, respectively. The values of the intra ligand $\mathrm{N}-\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ bond distances
have their typical values, and are in agreement with those reported for the free bmtz molecule (Glöckle et al., 2001).

The 1-D polymer in 2e comprises two very similar chains running along the crystallographic $b$ axis, which each chain containing three unique $\operatorname{Ag}(\mathrm{I})$ ions as shown in Figure 2.16. Significant $\pi-\pi$ stacking and anion $-\pi$ interactions occur between the 1D chains, generating a 2-D ladder supramolecular architecture as shown in Figures 2.17 and 2.18. The $\pi-\pi$ contacts ( $C_{g} \cdots C_{g}$ distances) are in between 3.571 to $4.440 \AA$. The anion $-\pi$ ( $\mathrm{O} \cdots C_{g}$ distances) interactions range from 2.672 to $3.241 \AA$. The neighbouring layers are additionally interlinked by $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. The combination of the anion $-\pi, \pi-\pi$, and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interactions generates a 3-D supramolecular architecture. All relevant interactions in $\mathbf{2 e}$ are listed in Tables 2.11 to 2.13.

### 2.3.6 Structural Description of $\left[\mathrm{H}_{2} \mathrm{bptz}\right]\left(\mathrm{NO}_{3}\right)_{2}(2 f)$

Unexpected red crystals of composition $\left[\mathrm{H}_{2} \mathrm{bptz}\right]\left(\mathrm{NO}_{3}\right)_{2}$ were obtained by the 1:1 metal:ligand ratio reaction of $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ and bptz in MeCN at $4{ }^{\circ} \mathrm{C}$. The crystal structure of 2f contains a half molecule of $\mathrm{H}_{2}$ bptz (generated by inversion symmetry to the other half) and one nitrate anion in the asymmetric unit as shown in Figure 2.19. $\mathbf{2 f}$ is a protonated amine salt compound in which the positive charge is localized at the $\mathrm{H}_{2} \mathrm{bptz}$ atom N1. The protonation of the $\mathrm{H}_{2}$ bptz ligand is most likely the result of hydrolysis of the $\mathrm{Fe}^{\text {III }}$ (Batten et al., 1998). The bond lengths of the $\mathrm{H}_{2} \mathrm{bptz}$ ligand are within the normal range (Klein et al., 1998). The ligand as a whole
is not planar due to the strengths of the noncovalent interactions which occur between the moieties.

Figure 2.19 The structure of $\mathbf{2 f}$, showing $50 \%$ probability displacement ellipsoids with atom numbering scheme. Hydrogen atoms are shown as small spheres of arbitrary radii. Hydrogen bonds are shown as dash lines. The labeling scheme, $A$ and $B$, applied for phenyl rings and are used to identity the rings in subsequent discussion.

Each cation molecule of $\mathrm{H}_{2}$ bptz is connected to two different $\mathrm{H}_{2}$ bmtz cations by the nitrate anion into a 2-D sheet via strong $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Table 2.11). Atoms N1 and C4 act as hydrogen bond donors atoms O3 and O1 $(-0.5+x, 0.5+y, z)$, respectively, $[\mathrm{N} 1-\mathrm{H} 1 \cdots \mathrm{O} 3=2.772(1) \AA, \mathrm{C} 4-\mathrm{H} 4 \cdots \mathrm{O} 1(1 / 2-x$, $1 / 2-y,-z)=3.072(1) \AA$ ] , generating open square grid cavities with distorted $(4,4)$ topology, as shown in Figure 2.20. The 2-D sheets are then interact to each other
through intermolecular anion $-\pi, \pi-\pi$ stacking, and additional weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding interactions to produced a 3-D supramolecular architecture (Tables 2.11 to 2.13).

### 2.4 Conclusions

This chapter describes new silver(I) coordination polymers, which are built up through the combination of silver-coordination, $\mathrm{Ag}-\pi$, anion $-\pi$, hydrogen bonding, and $\pi-\pi$ stacking interactions to generate novel supramolecular architectures. Structural studies on the resulting complexes demonstrate that the multidonal N -donor bmtz, $\mathrm{H}_{2}$ bmtz and bptz ligands can act as useful multiple bridging ligands for the $\mathrm{Ag}(\mathrm{I})$ ion. Reaction of the bmtz ligand with $\mathrm{AgClO}_{4}$ gave 1-D chains of $\mathbf{2 a}$ and $\mathbf{2 b}$. The $\left[\mathrm{ClO}_{4}\right]$ ions are coordinated to the $\mathrm{Ag}(\mathrm{I})$ ions in $\mathbf{2 a}$, but they are isolated in $\mathbf{2 b}$. The structures also differ by the incorporation of solvent molecules (2b). When the $\mathrm{H}_{2} \mathrm{bmtz}$ and bmtz ligands are mixed with $\mathrm{Ag}(\mathrm{tcm})$ in MeCN , they afford different kinds of coordination polymers: 1-D chains (2c) and 2-D sheets (2d). The reaction of bptz ligand with 1 equivalent of $\mathrm{AgNO}_{3}$ in MeCN gave a 1-D chain (2e). The nitrate ion in $\mathbf{2 e}$ is coordinated to the silver ions, similar to the perchlorate ion found in $\mathbf{2 a}$. When the same ligand is employed with $\mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ in MeCN , the unexpected salt $2 \mathbf{f}$ is obtained. Interestingly, the component ions in $2 f$ are connected into a 2-D sheet via strong and weak hydrogen bonds. The 2-D sheet is further constructed to a 3-D supramolecular structure through anion $-\pi$ interactions.

## CHAPTER III

## SYNTHESIS, STRUCTURES

## AND MAGNETIC PROPERTIES OF NEW CYANIDEBRIDGED BIMETALLIC COMPOUNDS

### 3.1 Introduction

An enormous amount of research work has been considerable interest in the design and elaboration of multidimensional coordination polymer materials (Robson et al., 1992; Leininger et al., 2001; Batten, 2001; 2004; 2005; Moulton and Zaworotko, 2002, Janiak, 2003; Yaghi et al., 2003; Kitagawa et al., 2004; Kepert, 2006) due to their intriguing structural richness and also potential applications in electrical conductivity (Sato, 2003), molecular based magnets (Kahn and Martinez, 1998; Jensen et al., 1999; Ammala et al., 2000; Moliner et al., 2000; Niel et al., 2001; Maspoch et al., 2004; Chippindale et al., 2005), molecular absorption (Chui et al., 1999; Eddaoudi et al., 2002; Forster and Cheetham, 2002; Bradshaw et al., 2005; Kesanli et al., 2005; Dincá et al., 2006), and biological relevance (Henkel and Krebs, 2004). In the field of cyanide bridged metal chemistry, there has been carried out intensive research during the last three decades by chemists, physicists and materials scientists dealing with the highly insoluble 3-D Prussian blue (PB) and their more soluble Prussian blue analogues (PBs). This is because of their spectacular properties such as in the fields of spectroscopy (Franz et al., 2004; Szaciowski et al., 2006; Ward, 2006), nanoporosity i.e. the related properties of gas storage (Chapman et al.,

2005; Kaye and Long, 2005, 2007), molecular magnetism eg. single-molecule agnets, SMMs (Berlinguette et al., 2003; Wang et al., 2006), single-chain magnets, SCMs, (Salman et al., 2006), molecular-based photomagnets (Ohkoshi et al., 2006), highest $T_{\text {C }}$ molecule-based materials (Gadet et al., 1992; Arrio et al., 1996; Buschmann et al., 1998), and spin crossover materials (Kosaka et al., 2005; Nihei et al., 2005; Guennic et al., 2007; Munoz et al., 2007).

Cyanometallates of varying coordination geometry, such as heptacyanometallates $(\mathrm{III})\left[\mathrm{M}(\mathrm{CN})_{7}\right]^{4^{--}}$, hexacyanometallates $\left[\mathrm{M}(\mathrm{CN})_{6}\right]^{3-},\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]^{4-}$, pentacyanometallates $\left[\mathrm{ML}(\mathrm{CN})_{5}\right]^{3-}$ or tetracyanometallates $\left[\mathrm{ML}(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{ML}(\mathrm{CN})_{4}\right]^{-}$(where $\mathrm{M}=$ a paramagnetic transition metal center, $\mathrm{L}=$ bidentate chelating ligand) have been employed as building blocks to make polynuclear species. The L ligand not only allows solubilization of reactants but also allow lowering of dimensionality of the PBs into the molecular regime. (Verdaguer et al., 1999; Ohba et al., 2000; Bernhardt et al., 2005; Culp et al., 2005; Lescouĕzec et al., 2005).

Using some examples of hexacyanometallate-based coordination polymers, Okawa and co-workers have prepared a 3-D network containing the cubic $\left\{\mathrm{Fe}_{8} \mathrm{Ni}_{12}\right\}$ unit in compound of type $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{L})_{2}\right]_{3}\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \mathrm{X}_{2}$, where $\mathrm{L}=$ 1,2-ethylenediamine, trimethylenediamine, $\mathrm{X}=\mathrm{PF}_{6}^{-}, \mathrm{ClO}_{4}^{-}$using hexacynoferrate(II) anion $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]^{4-}$ as a building block. These compounds display a ferromagnetic interaction between the nearest $\mathrm{Ni}^{\mathrm{II}}$ ions through the diamagnetic $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]^{4-}(S=0)$ ion (Fukita et al., 1998). For the $\mathrm{Fe}^{\text {III }}(S=1 / 2)$ analogue, reactions of the $\left[\mathrm{Fe}^{\text {III }}(\mathrm{CN})_{6}\right]^{3-}$ building block with $\left[\mathrm{Cu}^{\mathrm{II}}(\operatorname{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$, afforded the compounds $\left[\mathrm{Cu}^{\mathrm{II}}(\operatorname{tnH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (1-D structure), $\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \cdot \mathrm{KCl} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ (2-D structure), and $\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2}\right.$ $\left.\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ (3-D structure), where $\mathrm{tn}=1,3$-diaminopropane. The magnetic
properties of compounds show the presence of weakly coupled $\mathrm{Cu}^{\text {II }}$ ions with weak ferromagnetic (2-D) or antiferromagnetic (1- and 3-D) interactions (Triki et al., 2006). For all these compounds, the synthetic processes involve the spontaneous reduction of the paramagnetic $\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{CN})_{6}\right]^{3-}$ anion into the diamagnetic $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]^{4-}$. The reduction of $\mathrm{Fe}^{\mathrm{III}}$ to $\mathrm{Fe}^{\mathrm{II}}$ in water is similar to those observed in the works of Murray, Spiccia and co-workers when making heptanuclear cluster of type $\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\text { tpa })\right\}_{6} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]^{8+}$, where tpa $=\operatorname{tris}(2$-pyridylmethyl)amine $($ Parker et al., 1996; Spiccia and Murray, 2004).

Recently, Julve et al. (Lescouězec et al., 2005), and Gao et al. (Zhang et al., 2005) have prepared a number of low-dimensional assemblies of cyanide-bridged heterobimetallic by using low-spin trivalent transition metal ion of formula $\left[\mathrm{M}(\right.$ bidentate $\left.)(\mathrm{CN})_{4}\right]$, where $\mathrm{M}=\mathrm{Fe}^{\mathrm{III}}$ and $\mathrm{Cr}^{\mathrm{III}}$ as building blocks. For example, single-chain magnets (SCMs) nanowires of ferrimagnetic bimetallic compounds $\left[\left\{\mathrm{Fe}^{\mathrm{III}}(\mathrm{L})(\mathrm{CN})_{4}\right\}_{2} \mathrm{Co}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{L}=1,10$-phen, 2,2'-bipy, were shown to exhibit slow magnetic relaxation and hysteresis effects (Lescouĕzec et al., 2003). 4,2ribbon like bimetallic chains in $\left[\left\{\mathrm{Cr}^{\text {III }}(1,10-\mathrm{phen})(\mathrm{CN})_{4}\right\}_{2} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ show ferromagnetic hysteresis loops with coercive fields $H_{\mathrm{c}}<5000 \mathrm{G}$ (Toma et al., 2005). Zigzag chains in $\left[\mathrm{Cr}^{\mathrm{III}}\left(2,2^{\prime}-\right.\right.$ bipy $)(\mathrm{CN})_{4} \mathrm{Mn}^{\text {II }}(\mathrm{dca})\left(2,2^{\prime}-\right.$ bipy $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathrm{H}_{2} \mathrm{O}$, and a ladder chains in $\left[\mathrm{Cr}^{\text {III }}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\text {II }}\left(\mathrm{N}_{3}\right)\left(\mathrm{CH}_{3} \mathrm{OH}\right)\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ display magnetic ordering with different critical temperatures $\left(T_{\mathrm{C}}\right)$ and critical fields $\left(H_{\mathrm{C}}\right)$ (Zhang et al., 2005). The $\mathrm{Ru}^{\mathrm{II}}$ analogs $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{L})(\mathrm{CN})_{4}\right]^{2-}$ have also been used extensively to make framework species and their emission spectral properties have been investigated (Ward, 2006; Xial et al., 2007)

In the above work using $\left[\mathrm{M}^{\mathrm{III}}(\text { bidentate })(\mathrm{CN})_{4}\right]^{-}$plus $\left[\mathrm{M}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{\text {n+ }}$ or $\left[\mathrm{M}(\mathrm{X})_{\text {eq }}\right]$, where $\mathrm{X}=\mathrm{N}_{3}^{-}, \mathrm{N}(\mathrm{CN})_{2}^{-}\left(\mathrm{dca}^{-}\right)$, there has been little effort given to directing the topology of the PB analog. The aim of the present work is to use the principles of crystal engineering to synthesize 1-D tube-like motifs of cyanidebridged bimetallic coordination polymers, and if successful, to make in comparisons to 2- and 3-D Prussian blue analogues. The main strategy is to combine the chelated tetracyanoferrate building block of formula $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]^{\mathrm{x}}$ and $\left[\mathrm{M}^{\prime}\left(\mathrm{L}^{\prime}\right)(\text { solvent })_{4}\right]$ (where $\mathrm{x}=1,2 ; \mathrm{M}=\mathrm{Fe}^{\mathrm{II}}$ and $\mathrm{Fe}^{\mathrm{III}} ; \mathrm{M}^{\prime}=$ first row transition metals; $\mathrm{L}=1,10-\mathrm{phen}$, 2,2'-bipy, en, tn; $L^{\prime}=e n, t n$ ). Since other dimensionality products (2-D and 3-D) or discrete CN -bridged clusters (square, etc.) are possible, the structural diversity and magnetic properties of such bimetallic compounds that formed during the attempts to make the 1-D tubes are also of much interest to the project. The synthesis, structural and magnetic properties of a range of new cyanide-bridged complexes $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy)(CN) $\left.)_{4 n}{ }^{\mathrm{II}}\right] \cdot \mathrm{MeOH}(3 \mathbf{a}),\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 b}),\left[\mathrm{Fe}^{\mathrm{II}}(1,10\right.$ -phen $\left.\left.)(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right\}\right] \cdot 5 \mathrm{H}_{2} \mathrm{O}(\mathbf{3 c}),\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{3 d})$, and $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right]$ 'solvent (3e) are reported.

### 3.2 Experimental Section

### 3.2.1 Materials and Physical Measurements

$\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Cu}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, 1,10$-phen, 2,2'-bipy, en, and tn were purchased from commercial sources and used without further purification. $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{en})(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{tn})\right.$ $\left.(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (Goto, 1986), and $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}, \mathrm{H}\left[\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime}-\right.\right.$ bipy $)$ $\left.(\mathrm{CN})_{4}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(1,10-\right.$ phen $\left.)(\mathrm{CN})_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{H}\left[\mathrm{Fe}^{\mathrm{III}}(1,10-\right.$ phen $\left.)(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$
(Schilt, 1960) were prepared according to the literature.
Caution!: Cyanide is very poisonous. Great care was taken so that its salts did not come into contact with acid, which would liberate highly toxic hydrogen cyanide gas. Since $\mathrm{CN}^{-}$salts should not be touched with the fingers; use a spatula or handle small pieces with pincers, and reactants were performed under a fume hood.

Microanalytical measurements ( $\mathrm{C}, \mathrm{H}, \mathrm{N}$ ) were performed by Campbell Microanalytical Laboratory, Chemistry Department, University of Otago, Dunedin, New Zealand. Infrared spectra of Nujol mulls were recorded using a diamond-ATR cell on a Bruker Opus/IR IFS 55 spectrometer in the range of $600-4000 \mathrm{~cm}^{-1}$ (50 scans, resolution $\left.\pm 4 \mathrm{~cm}^{-1}\right]$. Variable-temperature magnetic susceptibility data were obtained by Dr. Boujemaa Moubaraki, Monash University using a Quantum Design MPMS 5 SQUID magnetometer for DC magnetization measurements.

### 3.2.2 Syntheses

## Preparation of Precursor Complex $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$

The 1:1 complex $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ readily crystallizes as large blue plates from methanolic solutions of nickel nitrate hexahydrate and ethylenediamine mixed in 1:1 stoichiometric amounts. Typically, a methanol solution (15 mL) of ethylenediamine ( $0.60 \mathrm{~g}, 0.01 \mathrm{~mol}$ ) was added dropwise to a methanol solution (15 $\mathrm{mL})$ of $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(2.91 \mathrm{~g}, 0.01 \mathrm{~mol})$ with constant stirring for one hour and filtered to remove any undissolved solid. The filtrate was allowed to stand to slowly evaporate, at room temperature. After one month, large blue plates were obtained (Yield $2.55 \mathrm{~g}, 88 \%$ ). The unit cell parameters of a representative crystal were identical to the cell parameters reported by McDougall and Hancock (1980). Anal. Found (calcd) for $\mathrm{C}_{2} \mathrm{H}_{16} \mathrm{~N}_{4} \mathrm{NiO}_{10}$ ( $\mathrm{Mr}=314.86 \mathrm{~g} / \mathrm{mol}$ ): C, $7.60(7.63)$; $\mathrm{H}, 5.08(5.12)$,
$\mathrm{N}, 17.82(17.79)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 684 \mathrm{~s}, 843 \mathrm{w}, 863 \mathrm{w}, 924 \mathrm{w}, 1047 \mathrm{w}, 1098 \mathrm{~s}$, $1115 \mathrm{~m}, 1163 \mathrm{~s}, 1292 \mathrm{w}, 1341 \mathrm{w}, 1396 \mathrm{w}, 1438 \mathrm{w}, 1463 \mathrm{~m}, 1575 \mathrm{~s}, 1982 \mathrm{w}, 2115 \mathrm{w}$, $2324 \mathrm{w}, 2657 \mathrm{w}, 2853 \mathrm{~s}, 2926 \mathrm{~s}, 3123 \mathrm{~m}, 3222 \mathrm{~s}$, $3286 \mathrm{~s} . \mu_{\mathrm{eff}}(\mathrm{RT})=3.2 \mu_{\mathrm{B}}$.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2}, 2^{\prime}-\right.\right.$-bipy $\left.)(\mathrm{CN}) \mathbf{4}_{4} \mathrm{Mn}^{\mathrm{II}}\right] \cdot \mathrm{MeOH}$ (3a)

A single crystal of 3a suitable for X-ray crystallographic analysis was obtained by slow diffusion in which aqueous methanolic (1:1, v/v) solutions of 14 mL capacity were contained in an H-shaped tube and left in the dark. In a typical experiment, $\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(245 \mathrm{mg}, 1 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ to form a colorless solution and this was pipetted into one side of the $\mathrm{H}-$ tube. $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}(113 \mathrm{mg}, 0.25 \mathrm{mmol})$ was dissolved in 3 mL of distilled water to give a deep red solution and this was pipetted into the other side arm of the H-tube. The H -tube was then carefully filled with $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$. Upon slow diffusion for two weeks, red plate-shaped single crystals of $\mathbf{3 a}$ were formed in the iron-containing side of the $H$-tube. Yield: $42 \mathrm{mg}, 37 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy) $\left.(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{29} \mathrm{H}_{20} \mathrm{Fe}_{2} \mathrm{Mn}_{2} \mathrm{~N}_{12} \mathrm{O}(\mathrm{Mr}=774.12 \mathrm{~g} / \mathrm{mol})$ : C, $44.26(44.69) ; \mathrm{H}, 2.89(3.00), \mathrm{N}, 20.51(20.85)$. ATR-FTIR ( $v_{\max } / \mathrm{cm}^{-1}$ ): 649br, 731 s , 766s, 1008m, 1062w, 1155m, 1244w, 1314w, 1425w, 1441m, 1470s, 1603s 2056s. $\mu_{\text {eff }}(300 \mathrm{~K})=8.01 \mu_{\mathrm{B}}$, per $\mathrm{Fe}_{2} \mathrm{Mn}_{2}$.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3b)

A sample of $\mathbf{3 b}$ was prepared in analogous way to $\mathbf{3 a}$ in which $\mathrm{H}\left[\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime}-\right.\right.$ bipy) $\left.(\mathrm{CN})_{4}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ was used instead of $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$. Red blockshaped crystals of $\mathbf{3 b}$ were formed in the manganese-containing side of the H -tube within three weeks. The $\mathrm{Fe}^{\text {III }}$ precursor was reduced to $\mathrm{Fe}^{\text {II }}$. Yield: $23 \mathrm{mg}, 33 \%$ based
on $\mathrm{H}\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{14} \mathrm{H}_{12} \mathrm{FeMnN}_{6} \mathrm{O}_{2}(\mathrm{Mr}=$ $407.08 \mathrm{~g} / \mathrm{mol}$ ): C, $41.04(41.31)$; H, 2.61(2.97), N, 20.27(20.65). ATR-FTIR ( $v_{\max } /$ $\mathrm{cm}^{-1}$ ): $717 \mathrm{w}, 856 \mathrm{w}, 958 \mathrm{w}, 1178 \mathrm{~s}, 1217 \mathrm{~s}, 1369 \mathrm{~m}, 1388 \mathrm{~m}, 1438 \mathrm{w}, 1461 \mathrm{w}, 1599 \mathrm{~m}$, 1982w, 2051w, 2166w, 2286m, 2314w, 2944w, 2996m, 3404w. $\mu_{\text {eff }}(300 \mathrm{~K})=5.93$ $\mu_{\mathrm{B}}$, per FeMn.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathbf{1}, 10-\mathrm{phen})(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 5 \mathrm{H}_{2} \mathrm{O}(3 \mathrm{c})$

A sample of $\mathbf{3 c}$ was prepared following the procedure described above for $\mathbf{3 a}$ using aqueous solutions, except that $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(1,10\right.$-phen $\left.)(\mathrm{CN})_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ was used instead of $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$. Typically, $\mathrm{Cu}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(70 \mathrm{mg}, 0.2 \mathrm{mmol})$, and tn (stock solution, $0.01 \mathrm{~mL}, 0.2 \mathrm{mmol}$ ) were dissolved in 3 mL of distilled $\mathrm{H}_{2} \mathrm{O}$ to form a blue solution of $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$, in situ, and this was pipetted into one side of the H-tube. $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(1,10\right.$-phen $\left.)(\mathrm{CN})_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}(90 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 3 mL of distilled $\mathrm{H}_{2} \mathrm{O}$ to give a deep red solution and this was pipetted into the other side arm of the H -tube. The H-tube was then carefully filled with distilled $\mathrm{H}_{2} \mathrm{O}$. Slow diffusion for three weeks yielded dark red needle-shaped crystals of $\mathbf{3 c}$, which were formed in the $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$ containing side. Yield: $50 \mathrm{mg}, 72 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Fe}(1,10-\right.$ phen $\left.)(\mathrm{CN})_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{19} \mathrm{H}_{28} \mathrm{CuFeN}_{8} \mathrm{O}_{5}\left(M_{r}=\right.$ $603.90 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 37.58(37.79)$; H, $5.32(5.34), \mathrm{N}, 18.42(18.56)$. ATR-FTIR ( $v_{\max } /$ $\mathrm{cm}^{-1}$ ): $649 \mathrm{br}, 731 \mathrm{~s}, 766 \mathrm{~s}, 1008 \mathrm{~m}, 1062 \mathrm{w}, 1155 \mathrm{~m}, 1244 \mathrm{w}, 1314 \mathrm{w}, 1425 \mathrm{w}, 1441 \mathrm{~m}$, 1470s, 1603s, 2056s, 2123w, 2254m, 2309w, 2943w, 3012m, 3414w. $\mu_{\text {eff }}(300 K)=$ $2.02 \mu_{\mathrm{B}}$, per FeCu.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2}, \mathbf{2}^{\prime}-\right.\right.$ bipy $\left.)(\mathbf{C N}) \mathbf{C l u}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (3d)

A sample of $\mathbf{3 d}$ was prepared analogously to $\mathbf{3 c}$ in which $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was used instead of $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}(1,10\right.$-phen $\left.)(\mathrm{CN})_{4}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$. Brown-red needle-shaped crystals $3 \mathbf{d}$ were formed in the $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$ containing side within three weeks. Yield: $48 \mathrm{mg}, 68 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{17} \mathrm{H}_{19} \mathrm{CuFeN}_{8} \mathrm{O}$ ( $\mathrm{Mr}=470.78 \mathrm{~g} / \mathrm{mol}$ ): C, 43.48(43.37); $\mathrm{H}, 4.38$ (4.07), N, $23.89(23.80)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 647 \mathrm{w}, 732 \mathrm{w}, 761 \mathrm{w}, 963 \mathrm{w}, 1025 \mathrm{w}$, $1159 \mathrm{w}, 1240 \mathrm{w}, 1278 \mathrm{w}, 1313 \mathrm{w}, 1425 \mathrm{w}, 1444 \mathrm{w}, 1582 \mathrm{~m}, 1603 \mathrm{~m}, 1995 \mathrm{w}, 2056 \mathrm{~s}$, $2103 \mathrm{~m}, 2904 \mathrm{w}, 3161$ br, 3256 br. $\mu_{\mathrm{eff}}(300 \mathrm{~K})=1.78 \mu_{\mathrm{B}}$, per FeCu.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2 , 2} \mathbf{2}^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Ni}^{\text {II }}(\mathrm{en})_{2}\right] \cdot$ Solvent (3e)

A sample of $\mathbf{3} \mathbf{e}$ was prepared following the procedure described above for $\mathbf{3 a}$ using aqueous methanolic (1:1, v/v) solutions. In a typical experiment procedure, $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}(63 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ solution to form a bright blue solution and this was pipetted into one side of the H tube. $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}(90 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ solution to give a bright yellow solution and this was pipetted into the other side arm of the H -tube. The H -tube was then carefully filled with $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ solution. Upon slow diffusion for two months, deep red plate shaped single crystals of 3e were formed in both sides of the H-tube with red powder precipitate. Yield: 18 mg , $15 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 990 \mathrm{w}, 1421 \mathrm{w}$, 1444w, 1467w, 1570w, 1592w, 2051s, 2067w, 2091m, 2325w, 2879m, 2929m, 3167w, 3245w, 3295w, 3318w, 3342w, 3358w, 3443w, 3634s. $\mu_{\text {eff }}(300 \mathrm{~K})=3.08 \mu_{\mathrm{B}}$, per FeNi.

### 3.2.3 X-Ray Crystallographic Study

Single crystals of $\mathbf{3 a -} \mathbf{- 3 e}$ were mounted on a MiTeGen MicroMounts fiber in a small amount of oil and quench cooled to $123(2) \mathrm{K}$ prior to measurements made by Dr. Suzanne M. Neville and Dr. Craig Forsyth, Monash University. Reflection intensities were collected on a Bruker X8 APEX CCD diffractometer (Mo $K_{\alpha}$ radiation, $\bar{\lambda}=0.71073 \AA$ ) and equipped with an Oxford Instruments nitrogen gas Cryostream. Empirical absorption corrections were applied to all data using SADABS (Blessing, 1995). The structures were solved using SHELXS-97 and refined on $F^{2}$ using SHELXL-97 (Sheldrick, 1997) with X-SEED (Barbour, 2001) as a graphics interface. In the final cycles of refinement, all atoms except hydrogen atoms and disordered molecules were refined anisotropically. However, special crystal structure refinement details for each compound are described below.

3a: The methanol molecules were found to be disordered about a $2_{1}$ screw axis, and were modeled in two different orientations. The total occupancy of both orientations was fixed to one. Restraints were applied to the displacement parameters of this disordered molecule. In the final cycles of refinement, all atoms except hydrogen atoms were refined anisotropically. Hydrogen atoms attached to carbon atoms of $2,2^{\prime}$-bipy molecules were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}$ distance at $0.95 \AA$, with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C}, \mathrm{N})$ [1.5 $U_{\mathrm{eq}}(\mathrm{C})$ for methyl hydrogen atoms].

3b: The coordinated water molecules exhibited large displacement parameters, were modeled assuming a three-site disorder about a $\overline{3}$ axis; the occupancy factors for the three components were allowed to vary and their summation was set to one. The poor crystal quality also resulted in broad diffraction peaks. The hydrogen atoms of
the water molecules are very labile and difficult to locate. Thus no hydrogen atoms were located for any of the water molecules. Hydrogen atoms attached to carbon atoms of $2,2^{\prime}$-bipy molecules were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}$ distance at $0.95 \AA$, with $U_{\mathrm{iso}}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C}, \mathrm{N})$.

3c: Hydrogen atoms attached to oxygen atoms of the water molecules were located in a difference Fourier map and refined as riding in their as-found positions with a DFIX restraint of $\mathrm{O}-\mathrm{H}$ distance at $0.90 \AA$, with $U_{\mathrm{iso}}(\mathrm{H})=1.2 U_{\mathrm{eq}}(\mathrm{O})$. Hydrogen atoms bound to carbon or nitrogen atoms of th molecules were positioned geometrically and refined as riding atoms with $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ distances of 0.97 and $0.86 \AA$, respectively, and $U_{\text {iso }}(\mathrm{H})$ values of $1.2 U_{\mathrm{eq}}(\mathrm{C}, \mathrm{N})$. Hydrogen atoms attached to carbon atoms of 1,10-phen molecules were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}$ distance at $0.95 \AA$, with $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\mathrm{eq}}(\mathrm{C}, \mathrm{N})$.

3d: The cell parameters of 3d indicated a triclinic cell $(a=6.6150 \AA, b=$ $\left.12.0449 \AA, c=15.1964 \AA, \alpha=69.659^{\circ}, \beta=77.970^{\circ}, \gamma=80.201^{\circ}, V=1104.04 \AA^{3}\right)$ and the $R_{\mathrm{int}}$ value for the triclinic crystal system was 0.187 . The structure was solved in the triclinic space group $P \overline{1}$ using direct methods. After encountering severe problems during structure solution, anisotropic refinement remained stalled at $R_{1}=$ 0.131 and $w R_{2}=0.357$, with several atoms going nonpositive definite. Despite many attempts to re-grow the crystals, the only brown-red needle microcrystals obtained were always small and often twinned and of poor quality. However, the elementary analysis of the obtained crystalline product is consistent with the $\mathrm{C}, \mathrm{H}$ and N values expected for the formula of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}$.

3e: Solvents molecules were found to be disordered, and were modeled in two different orientations. The total occupancy of both orientations was fixed to one. Hydrogen atoms bound to carbon or nitrogen atoms of en molecules were positioned geometrically and refined as riding atoms with $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ distances of 0.97 and $0.86 \AA$, respectively, and $U_{\mathrm{iso}}(\mathrm{H})$ values of $1.2 U_{\mathrm{eq}}(\mathrm{C}, \mathrm{N})$. Hydrogen atoms attached to carbon atoms of $2,2^{\prime}$-bipy molecules were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}$ distance at $0.95 \AA$, with $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\mathrm{eq}}(\mathrm{C}, \mathrm{N})$.

Crystal data and details of the data collection and structure refinement for compounds 3a-3c and 3e are summarized in Table 3.1. The relatively high $R$ values for some compounds were due to the low quality of the crystals and disorder of solvent molecules. Selected interatomic bond lengths and angles for compounds $\mathbf{3 a}$ $\mathbf{3 c}$ and 3e are given in Tables 3.2 to 3.5. The bond lengths and angles, hydrogen bonds geometry, and other crystallographic data are given as supplementary material in the CIF which can be found on the attached CD-ROM.

Table 3.1 Summary of crystallographic data for the compounds $\mathbf{3 a - 3 c}$ and $\mathbf{3 e}$.

### 3.3 Results and Discussion

### 3.3.1 Synthesis and ATR-FTIR Spectra

Many attempts were made to grow single crystals of the proposed 1-D tube motifs in cyanide-bridged bimetallic products by using the complexes of formula $\left[\mathrm{M}(\mathrm{L})(\mathrm{CN})_{4}\right]$ and $\left[\mathrm{M}^{\prime}\left(\mathrm{L}^{\prime}\right)(\text { solvent })_{4}\right]\left(\right.$ where $\mathrm{M}=\mathrm{Fe}^{\mathrm{II}}$ and $\mathrm{Fe}^{\mathrm{III}} ; \mathrm{M}^{\prime}=\mathrm{Mn}^{\mathrm{II}}, \mathrm{Co}^{\mathrm{II}}, \mathrm{Ni}^{\mathrm{II}}$, $\mathrm{Cu}^{\text {II }}, \mathrm{Zn}^{\mathrm{II}}$, and $\mathrm{Cd}^{\mathrm{II}} ; \mathrm{L}=1,10-$ phen, $2,2^{\prime}$-bipy, en, $\mathrm{tn} ; \mathrm{L}^{\prime}=\mathrm{en}, \mathrm{tn}$ ) as building blocks. Initially, the precursor $\mathrm{Na}_{2}\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{L}(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, where L is an aliphatic diamine en and tn, were chosen as building blocks in order to minimize any chelate ligand steric effects on trying to form the $\left[(\mathrm{L})-\mathrm{Fe}-(\mathrm{CN})_{2}-\mathrm{M}^{\prime}-\left(\mathrm{L}^{\prime}\right)\right]_{2}$ square moieties. These ironcyano building blocks were successfully prepared, in large scale and high yield, by a literature procedure (Goto et al., 1986), and were phase pure as evidenced by microscopic examination and microelemental analysis. The first compound in this "square tube" study was successfully synthesized via in situ reaction, at room temperature, using $\mathrm{Na}_{2}\left[\mathrm{Fe}(\mathrm{tn})(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Ni}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ as building blocks. Two different types of crystals, with distinctly different crystal morphologies and colors, were grown. The crystals were small red blocks and large purple blocks. Magnetic measurement on polycrystalline bulk samples display interesting long-range magnetic order with and ordering temperature, $T_{\mathrm{C}}=16.0 \mathrm{~K}$.

Surprisingly, single crystal X-ray crystallographic studies, and subsequent confirm of the metal contain by EDX, revealed that no iron was detectable in both types of crystal. The crystal structure showed that a cyanide-bridged homometallic compound $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right]$ had formed that contains two kinds of coordination geometry around Ni centres, i.e. octahedron and square planar, in a 3-D network array. This prompted to further investigations of the "ligand complex" tetracyanonic-
kelate, $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{CN})_{4}\right]^{2-}$. This square-planar moiety was employed as a building block to react with $\left[\mathrm{Ni}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ in aqueous methanolic (1:1) solutions, to afford a 3-D cyanide-bridged network complex $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{CN})_{4} \mathrm{Ni}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeOH}(\mathbf{5 b})$, in which elucidation of the magnetic measurements provided results consistent with the single crystal X-ray crystallographic and elemental (C, H, N) analyses (see Chapter V). Therefore, the long-range magnetic order first observed was presumably due to the presence of impurity phases in the initial bulk sample. The identify of the impurity phase is not known but we note that $\mathrm{Fe}^{\mathrm{III}}-\mathrm{CN}-\mathrm{Ni}^{\mathrm{II}}$ coordination polymer often yield $T_{\mathrm{C}}$ values of similar size (Ohba et al., 1994).

This result showed that the mono-chelated $\mathrm{Fe}(\mathrm{II})$ complexes $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{L})(\mathrm{CN})_{4}\right]^{2-}$, $\mathrm{L}=\mathrm{en}$ and tn , are labile in aqueous media, and prone to $\mathrm{Fe}^{\mathrm{II}}$ substitution, eg. by $\mathrm{Ni}^{\mathrm{II}}$, as well as loss of the diamine. So far, although four structures have been solved and refined by single crystal X-ray analysis, the mono-chelated en- or tn-Fe(II) complexes were not found in the products. Therefore, this prompted use of the $2,2^{\prime}$-bipy and 1,10-phen chelate ligands instead which, though having bulkier size, form LS Fe(II) complexes that are usually more stable and less prove to loss of the bidentate ligand than are the mono-chelated $\mathrm{Fe}(\mathrm{II})$ complex of en and tn .

The $\left[\mathrm{Fe}\left(1,10 \text {-phen or } 2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ building block has excellent solubility in water but very small solubility in common organic solvents, i.e. MeOH , EtOH , and MeCN . Mixed aqueous solvents such as $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeOH}, \mathrm{H}_{2} \mathrm{O} / \mathrm{EtOH}$, $\mathrm{H}_{2} \mathrm{O} / \mathrm{MeCN}, \mathrm{H}_{2} \mathrm{O} /$ DMF were also used as crystallization solvents in order to avoid solvents in which the precursor is too soluble and tend to give too small a size in the product crystals. After many attempts, it was found that the best solvent contravention needed to obtain single crystals suitable for X-ray structure determination was the
mixtures of water and methanol ( $\mathbf{3 a}, \mathbf{3 b}$, and $\mathbf{3 e}$ ) or water alone ( $\mathbf{3} \mathbf{c}$ and $\mathbf{3 d}$ ) and an H tube was the best crystallizing vehicle. Typical synthesis details can be seen in the

H-tube apparatus with $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4}\right]^{2-}$ on left experimental section. Notably, when crystals begin to grow, they have to be kept in a sealed H-tube with some mother liquor present to prevent the crystals from drying out since single perfect crystals may contain solvent of crystallization in the lattice. Loss of this solvent from the crystals can result in the crystal lattice breaking down, and the crystals turning to powder.

Surprisingly, in the case of complex 3a and 3b, obtained from $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right]^{-}$, respectively, the crystal structures showed the same +2 charge on the iron centres. In keeping with the $\mathrm{Fe}^{\text {III }} \rightarrow \mathrm{Fe}^{\text {II }}$ reduction hypothesis similar reduction has been shown to occur in the heme-based NO carrier nitrophorin and in other Feprotein systems (Ascenzi and Fasano, 2007). Hexacyanoferrate anion, particular ferricyanide ions are not extremely stable even in aqueous solution. Their oxidation/reduction processes from $\mathrm{Fe}^{\mathrm{II}} \rightarrow \mathrm{Fe}^{\mathrm{III}}$ and vice versa have also been studies in mixed cyano-bridged clusters (Parker et al., 2002). Therefore, the reduction of the $\mathrm{Fe}^{\text {III }} \rightarrow \mathrm{Fe}^{\mathrm{II}}$ in $\mathbf{3 b}$ may be caused by the presence of cyanide which itself acting as the reducing agent in aqueous media. However, the four $\mathrm{CN}^{-}$ligands of the $\mathrm{Fe}^{\text {III }}$ precursor are retained in the $\mathrm{Fe}^{\mathrm{II}}$ product, $\mathbf{3 b}$, and thus free $\mathrm{CN}^{-}$would have to be in the other $60 \%$ of product/solution not accounted for (see Experimental) $\mathrm{Mn}^{\mathrm{II}}$ and methanol are the only other possible reductants in the reaction vessel. In future, it
would be instructive to use the precursor $\left[\mathrm{Cr}^{\mathrm{III}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{-}$.
The types of cyanide coordination are best monitored by infrared spectral studies. The assignments of the $v(\mathrm{CN})$ bands of product compounds and of precursors in the present study are given in the Table 3.6. Typically, bridging cyanide ligands have higher $v(\mathrm{CN})$ frequencies than the terminal cyanides (Nakamoto, 1963), since coordination usually weakens the ligand bond next to the coordination bonds, thus shifting the ligand stretching vibration to a lower frequency. As expected, the CN stretching band is shifted to higher wavenumbers by about $20 \mathrm{~cm}^{-1}$ compared to the tetracyanoferrate(II) building blocks when a CN group is bridged to a second metal ions. The IR bands due to coordinated chelate, $v(\mathrm{NH})$ and $v(\mathrm{OH})$ groups are given in the Experimental (synthesis) section.

### 3.3.2 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\right] \cdot \mathrm{MeOH}$ (3a)

The X-ray single crystal structure analyses at 123 (2) K reveals that compound 3a crystallizes in the monoclinic system with space group $P 2_{1} / c$ (No. 14). The asymmetric unit consists of two $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2+}$ anions, two $\mathrm{Mn}^{\mathrm{II}}$ cations, and two methanol molecules of crystallization.

As shown in Figure 3.1, a crystallographically independent unit contains two types of iron ( Fe 1 and Fe 2 ) and manganese ( Mn 1 and Mn 2 ). Each $\mathrm{Fe}(\mathrm{II})$ atom is located in a distorted octahedral environment formed by two nitrogen atoms from a $2,2^{\prime}$-bipy ligand and four cyanide carbon atoms. The $\mathrm{Fe}-\mathrm{N}_{2,2^{\prime}-\text { bipy }}$ and $\mathrm{Fe}-\mathrm{C}_{\mathrm{CN}}$ bond lengths in 3a range from $1.973(6)$ to $2.001(6) \AA$, and $1.868(7)$ to $1.920(7) \AA$, respectively. These values are in agreement with the $\mathrm{Fe}-\mathrm{N}$ and $\mathrm{Fe}-\mathrm{C}$ bond lengths as observed in the $\mathrm{Fe}(\mathrm{II})$ complexes such as $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 2.5 \mathrm{H}_{2} \mathrm{O}$ (Nieuwenhuyzen et al., 1998) and $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (Toma et al., 2002). The three trans angles of $[\mathrm{C}-\mathrm{Fe}-\mathrm{N}]$ and $[\mathrm{C}-\mathrm{Fe}-\mathrm{C}]$ range from 171.7(3) to $175.7(3)^{\circ}$, which are somewhat bent from the ideal value of $180^{\circ}$. The $\mathrm{Fe}-\mathrm{C}-\mathrm{N}$ angles for bridging cyanide ligands range between $174.2(6)$ and $178.3(7)^{\circ}$.

The 2, $2^{\prime}$-bipy ligand in 3a exhibits usual acute $\mathrm{N} \cdots \mathrm{N}$ bite distances of 2.558(8) $\AA$ [ $\mathrm{N} 9 \cdots \mathrm{~N} 10$ ] and $2.578(8) \AA[\mathrm{N} 11 \cdots \mathrm{~N} 12]$. The bite angles are $80.5(2)$ and $80.7(2)^{\circ}$ for N9-Fe1-N10 and N11-Fe2-N12, respectively. These are one of the main factors accounting for the distortion from ideal octahedral geometry $\left(90^{\circ}\right)$ of $\mathrm{Fe}^{\mathrm{II}}$.

The 2,2'-bipy ligand, as a whole, is close to planar. The mean deviation (r. m. s. deviation of fitted atoms) from the best plane calculated using twelve atoms is $0.043 \AA$ for the plane 1 (rings $A$ and $B$ ) with the largest deviation is $-0.149(8) \AA$ at C 18 , whereas, r. m. s. deviation of fitted atoms is $0.074 \AA$ with the largest deviation
of $0.171(8) \AA$ at C 27 for the plane 2 (rings $C$ and $D$ ). The dihedral angle between the two planes is $3.9(1)^{\circ}$. The bond lengths and angles within the $2,2^{\prime}$-bipy groups are in agreement with that reported for the free $2,2^{\prime}$-bipy molecule (Merritt and Schroeder, 1956). The C1/C2/Fe1/N9/N10 and C5/C6/Fe2/N11/N12 sets of atoms define a fivemembered chelate to $\mathrm{Fe}^{\mathrm{II}}$, and are close to being coplanar, with the largest deviation from their mean plane being $0.093(3)$ and $-0.061(3) \AA$ at N 10 and N12, respectively.

Figure 3.1 Thermal ellipsoid plot of a fragment at the $50 \%$ probability level containing the asymmetric unit with atom numbering and showing coordination environments of metals centre in 3a. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $A-D$, applied to the phenyl rings is used to identify the rings in subsequent discussion. Symmetry codes: (i) $-1+x, y, z$; (ii) $x, 0.5-y,-0.5+z$; (iii) $x$, $0.5-y, 0.5+z$; (iv) $1+x, y, z$.

Interestingly, the $\mathrm{Mn}(\mathrm{II})$ centres adopt distorted tetrahedral geometry. Each Mn atom is coordinated by four nitrogen atoms from the cyanide-bridges of the $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ fragments. The $\mathrm{Mn}-\mathrm{N}$ bond lengths in 3a range from 2.057(6) to $2.114(6) \AA$, which compare well with those in other four-coordinated cyano-containing $\mathrm{Mn}(\mathrm{II})$ complexes such as $2.068(5) \AA\left[\left(4,4-\right.\right.$ bipyH$\left._{2}\right)\left[\mathrm{Mn}(\mathrm{NCS})_{4}\right]$ (Chen et al., 2000), and are comparable to the calculated average value ( $2.143 \AA$ ) for 31 tetrahedral Mn (II) complexes with a chromophore group $\mathrm{MnN}_{4}$ as revealed by a CSD search from CONQUEST software version 5.26, update January 2008 (Allen, 2002). There are, however, slight differences in bond lengths and angles around the $\mathrm{Mn}(\mathrm{II})$ centre caused by the disordered methanol molecules of crystallization that are close to the Mn 2 atoms. The relevant $\mathrm{N}-\mathrm{Mn}-\mathrm{N}$ bond angles vary between 92.7(3) and $128.2(4)^{\circ}$, and are therefore quite different to the ideal value of $109.5^{\circ}$, thus indicating the significant deviation from a regular tetrahedron. The $\mathrm{Mn}-\mathrm{N}-\mathrm{C}$ bond angles range from $156.2(6)$ to $176.8(10)^{\circ}$, which are somewhat more bent from linearity than are those of the $\mathrm{Fe}-\mathrm{N}-\mathrm{C}$ bond angles.

The bond lengths and angles within the cyanide ligand ranging from 1.151(10) to $1.171(11) \AA$ are normal, and are comparable to the $\mathrm{C}-\mathrm{N}$ bond distance in $\mathrm{NaCN} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (van Rij and Britton, 1978). From a bonding perspective, in the cyanide ions the carbon and nitrogen atoms act as $\pi$ acceptor and $\sigma$ donor, respectively. This Lewis acid-base character increases the $\pi$-bonding and $\sigma$-antibonding character of the Fe ion with the cyanide carbon and nitrogen atoms (Vahrenkamp et al., 1997). Therefore, as expected, the $\mathrm{Fe}^{\mathrm{II}}-\mathrm{C}_{\mathrm{CN}}$ bond lengths in compound 3a are shorter than the $\mathrm{Mn}^{\mathrm{II}}-\mathrm{N}$ bond lengths.

Figure 3.2 A projection along the $a$ axis showing the 2-D corrugated sheets in 3a. Included methanol molecules occupy the corrugated sheets.

Each $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ unit uses four cyanide groups to bridge to four $\mathrm{Mn}^{\mathrm{II}}$ cations. Simultaneously, each $\mathrm{Mn}^{\mathrm{II}}$ atoms is linked to four [ $\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.$-bipy $)$ $\left.(\mathrm{CN})_{4}\right]^{2-}$ units to form neutral 2-D corrugated $(4,4)$ sheets of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $)(\mathrm{CN})_{4}$ $\mathrm{Mn}^{\mathrm{II}}$ ], and the methanol molecules of crystallization lie within the sheets as shown in Figure 3.2. Within the 2-D corrugated sheets, the $\mathrm{M} \cdots \mathrm{M}$ distances through the cyanide bridges and the $\mathrm{M} \cdots \mathrm{M}$ distances across the square windows vary from $4.997(1)$ to 5.163(1) and 6.250(1) to 7.813(1) $\AA$, respectively, Figure 3.3.

Figure 3.3 Schematic view of the 2-D corrugated sheets of the bimetallic skeleton formed by cyanide-bridged $\mathrm{Fe}(\mathrm{II})$ and $\mathrm{Mn}(\mathrm{II})$ atoms in 3a. The $\mathrm{M} \cdots \mathrm{M}$ separations are 4.997(1) [Fe1-Mn1], 5.096(1) [Fe1-Mn2], 5.036(1) $\left[\mathrm{Fe} 1-\mathrm{Mn} 1^{\mathrm{i}}, \mathrm{Mn} 1-\mathrm{Fe}^{\mathrm{v}}\right], 5.163(1)$ [Fe1-Mn2 $\left.{ }^{\mathrm{ii}}, \mathrm{Mn} 2-\mathrm{Fe}^{\mathrm{iv}}\right], 5.027(1)$ [Fe2-Mn1], 5.072(1) [Fe2-Mn2], 5.050(1) [Fe2-Mn1 $\left.{ }^{\text {iv }}, \mathrm{Mn} 1-\mathrm{Fe} 2^{\mathrm{ii}}\right]$, and 5.003(1) $\AA\left[\mathrm{Fe} 2-\mathrm{Mn} 2^{\mathrm{v}}, \mathrm{Mn} 2-\mathrm{Fe} 2^{i}\right]$. The $\mathrm{M} \cdots \mathrm{M}$ distances across the squares are $7.813(1)[\mathrm{Fe} 1-\mathrm{Fe} 2], 7.219(1)\left[\mathrm{Fe} 1-\mathrm{Fe}^{2}{ }^{\mathrm{ii}}, \mathrm{Fe} 2-\mathrm{Fe} 1^{\mathrm{iv}}\right]$, 7.688(1) [Fe1-Fe2 ${ }^{\mathrm{iii}}$, $\left.\mathrm{Fe} 2-\mathrm{Fe}^{\mathrm{vi}}\right]$, 7.529(1) [ $\left.\mathrm{Fe} 1-\mathrm{Fe} 2^{\mathrm{i}}\right]$ 6.392(1) [Mn1$\mathrm{Mn} 2], 6.808(1)\left[\mathrm{Mn} 1-\mathrm{Mn} 2^{\mathrm{ii}}\right], 6.701(1)\left[\mathrm{Mn} 1-\mathrm{Mn}^{\mathrm{v}}\right]$, and $6.249(1) \AA$ $\left[\mathrm{Mn} 1-\mathrm{Mn} 2^{\mathrm{vii}}\right]$. Symmetry codes: (i) $1+x, y, z$; (ii) $x, 0.5-y,-0.5+z$; (iii) $1-x, 0.5-y,-0.5+z$; (iv) $x, 0.5-y, 0.5+z$; (v) $-1+x, y, z$; (vi) $-1+x, 0.5-y$, $0.5+z$; (vii) $-1+x, 0.5-y,-0.5+z$; (viii) $1+x, 0.5-y, 0.5+z$.

The packing of 3a viewed down the crystallographic $c$ axis is shown in Figure 3.4. The intercalated methanol molecules lie within the sheets. An extensive array of $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ type interactions between the sheets is also observed. For the $\mathrm{C}-\mathrm{H}^{\cdots} \pi$ interactions, the carbon atoms of the $2,2^{\prime}$-bipy molecules act as hydrogen bond donors, and are oriented perpendicular to the mid-point of the $\mathrm{C} \equiv \mathrm{N}$ groups (hydrogen bond acceptors) of neighboring sheets. The $\mathrm{H} \cdots \pi(\mathrm{C} \equiv \mathrm{N})$ interatomic distances range from 2.578 to $2.875 \AA$, which are typical of literature values (Desiraju and Steiner, 1999). The $2,2^{\prime}$-bipy molecules are also themselves stacked, forming a slipped and strictly face-to-face $\pi \cdots \pi$ interaction. The value of the $C_{\mathrm{g}} \cdots C_{\mathrm{g}}$

Figure 3.4 Packing diagram of 3a viewed along the $c$ axis showing $\pi \cdots \pi$ interactions between the 2-D corrugated sheets. Methanol molecules are represented as space-filling models.
distances range between 3.618 and $4.123 \AA$. These values may be indicative of weak $\pi \cdots \pi$ interactions (Janiak, 2000). The 2-D sheets in 3a are thus cross-linked by a combination of $\mathrm{C}-\mathrm{H} \cdots \pi$ and weak $\pi \cdots \pi$ interactions into a 3-D supramolecular network. These interactions presumably contribute to the stabilization of the structure. Details of such supramolecular interactions in 3a are given in Tables 3.7, and 3.8.

What is notable in Figures 3.1 and 3.3 is that the desired CN -bridged square $\{\mathrm{Fe} 1 / \mathrm{C} 1 / \mathrm{N} 1 / \mathrm{Mn} 1 / \mathrm{N} 5 / \mathrm{C} 5 / \mathrm{Fe} 2 / \mathrm{C} 6 / \mathrm{N} 6 / \mathrm{Mn} 2 / \mathrm{N} 2 / \mathrm{C} 2 / \mathrm{Fe} 1\}$ has been formed. However, it can not extend in to a square tube because of the two $2,2^{\prime}$-bipy ligands, and hence $\mathrm{C} 4 / \mathrm{N} 4$ and C7N7 extend outwards rather than at $90^{\circ}$ to the square. The $\mathrm{Mn}(\mathrm{II})$ centres, of course, lack a blocking bidentate ligand.

### 3.3.3 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2 , 2} \mathbf{2}^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3b)

The single crystal X-ray structure analyses at 123 (2) K reveals that compound 3b is isostructural to $\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (Xia et al., 2007) a compound reported during this project. 3b crystallizes in the high symmetry trigonal system with space group $R \overline{3}$ (No. 148). The asymmetric unit consists of one [ $\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.$-bipy) $\left.(\mathrm{CN})_{4}\right]^{2-}$ anion and one $\left[\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ cation, as shown in Figure 3.5.

Figure 3.5 Ball and strict representation of the asymmetric unit with numbering scheme and showing the coordination environments of the metal centres in 3b. Hydrogen atoms are omitted for clarity. The labeling scheme, $E-F$, applied to the phenyl rings is used to identify the rings in the subsequent discussion. Symmetry codes: (i) $x-y+1 / 3, x-1 / 3,-z+2 / 3$; (ii) $y+1 / 3,-x+y+2 / 3,-z+2 / 3$; (iii) $x, y, z-1$.

The Fe(II) centre is coordinated by two nitrogen atoms from one $2,2^{\prime}$-bipy and four cyanide carbon atoms, and has a distorted octahedral geometry. The $\mathrm{Fe}-\mathrm{C}$ bond lengths range from $1.870(10)$ to $1.940(10) \AA$, whereas the $\mathrm{Fe}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths are $1.997(9)$ and $1.980(8) \AA$. The bond lengths and angles involving the $2,2^{\prime}$-bipy ligand are normal (Merritt and Schroeder, 1956). The whole 2,2'-bipy ligand is not planar with r. m. s. of $0.137 \AA$, and the largest deviation from the best plane being $0.179(9)$ at C6. The values of the bond lengths and angles within the $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right]^{2-}$ unit are slightly different to those found in 3a, i.e. the $\mathrm{Fe}-\mathrm{C}-\mathrm{N}$ angles range from $171.3(10)$ to $177.1(9)^{\circ}$, and are thus more bent from linearity.

The $\mathrm{Mn}(\mathrm{II})$ center is coordinated in a distorted octahedral geometry by four nitrogen atoms from four bridging cyanide groups and two oxygen atoms from water molecules. The $\mathrm{Mn}-\mathrm{N}$ bond lengths range from 2.114(10) to $2.165(9) \AA$, whereas the $\mathrm{Mn}-\mathrm{O}$ bond lengths are 2.340(9) and 2.480(20) $\AA$. The $\mathrm{Mn}-\mathrm{N}-\mathrm{C}$ bond angles range from $140.6(9)$ and $175.4(9)^{\circ}$, and are much more significantly bent than the $\mathrm{Fe}-\mathrm{C}-\mathrm{N}$ bond angles above. The bond lengths and angles, however, for the $\left[\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ moieties of 3b are in accordance with those found in $\left[\mathrm{Ru}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (Xia et al., 2007).

As shown in Figures 3.6 and 3.7, the most significant structural feature of 3b is the assembly of the two distinct types of building blocks, i.e. [ $\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.$-bipy $)$ $\left.(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$, to form remarkable neutral hydrophilic 1-D tubular coordination polymers, running along the crystallographic $a$ axis. Each $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right]^{2-}$ unit connects to four $\mathrm{Mn}(\mathrm{II})$ cations via cyanide groups. Simultaneously, each Mn (II) ions is linked to four Fe (II) ions. The tube can be described in terms of 18 -membered $\left\{\mathrm{Fe}_{3} \mathrm{Mn}_{3}(\mathrm{CN})_{6}\right\}$ rings (Figure 3.6c). Within this

Figure 3.6 Views of (a) side, (b) top views of 1-D tubular structure, (c) $\mathrm{Fe}_{3} \mathrm{Mn}_{3}$ hexanuclear arrangement, and (d) schematic view of the tube topology (water and 2,2'-bipy molecules omitted for clarity) in $\mathbf{3 b}$.
open $\left\{\mathrm{Fe}_{3} \mathrm{Mn}_{3}\right\}$ hexanuclear arrangement, the angles of the three metal ions along the edges are $145.1(9)$ and $90.7(9)^{\circ}$ for $[\mathrm{Mn}-\mathrm{Fe}-\mathrm{Mn}]$ and $[\mathrm{Fe}-\mathrm{Mn}-\mathrm{Fe}]$, respectively. The r. m. s. deviation of fitted atoms from the best plane calculated using eighteen atoms in the ring is $0.196 \AA$. These rings, which have a triangular shape, then stack so that each ring is staggered $60^{\circ}$ to its neighbours. The stacked rings are then bridged by further cyanide ligands to generate the tube (Figure 3.6d).

The two side planes of the 1-D tube have a dihedral angle of $6.93(1)^{\circ}$. The cross dimension of the hexagon channel is $c a .9 .925(2) \AA$ (defined by the separation between Fe and Mn ), which is slightly larger than that found for the $\mathrm{Ru}^{\mathrm{II}}$ analog of 9.8 $\AA$ (Xia et al., 2007). The Fe $\cdots$ Mn separation across the cyanide bridges is $4.862(1) \AA$.

Figure 3.7 Views of (a) packing of the three and (b) single 1-D tubes in 3b. The brown color defined the tube.

Figure 3.8 (a) Stick and (b) space filling representations of seven 1-D tubes in top view of 3b. Water molecules are omitted.

As shown in Figure 3.8, one single nanotube is surrounded by six other nanotubes, and they extend in a parallel arrangement along the crystallographic $c$ axis to form a 3-D supramolecular architecture via $\pi-\pi$ interactions of overlapping phenyl rings, at interlayer distances of $c a .3 .79 \AA$. These interactions help to increase the dimensionality into a 3-D supramolecular structure, and help to stabilize the crystal structure in 3b.

In contrast to 3a, there are no methanol molecules of crystallization observed in the structure of $\mathbf{3 b}$. This is perhaps surprising looking at the tubular channels. If only the arrangement of the $\mathrm{Mn}(\mathrm{II})$ centres and cyanide ligands are considered, then the geometrical characteristics of the Mn (II) ion in $\mathbf{3 b}$ is very similar that of $\mathbf{3 a}$. Therefore the size of the clathrated solvents, i.e. water versus methanol is one factor
causing a significant difference between the structures of 3a and 3b. The topology observed in 3b is very rare for cyanide-bridged bimetallic coordination polymers. A search from CSD (version 5.28, updates January 2008) and SciFinder (July 2008) yielded only one example, a $\mathrm{Ru}(\mathrm{II})$ analog (Xia et al., 2007) of 3b, reported so far. The initial aim of this work was to isolate square tubes, ideally of $\mathrm{Fe}^{\text {III }} / \mathrm{Mn}^{\text {II }}$, but it is gratifying to have made hexagonal tubes.

### 3.3.4 StructuralDescription of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathbf{1 , 1 0 - p h e n})(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 5 \mathrm{H}_{2} \mathrm{O}(3 \mathrm{c})$

The X-ray single crystal structure analyses at $123(3) \mathrm{K}$ reveals that compound 3c crystallizes in the triclinic system with space group $P \overline{1}$ (No. 2). 3c contains a neutral cyanide-bridged $\mathrm{Fe}^{\mathrm{II}}-\mathrm{Cu}^{\mathrm{II}}$ rectangular tetranuclear complex which resides on a centre of symmetry. The asymmetric unit consists of one $\left[\mathrm{Fe}^{\mathrm{II}}(1,10-\mathrm{phen})(\mathrm{CN})_{4}\right]^{2-}$ anion, one $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ cation, and five uncoordinated water molecules. A view of the core part of $\mathbf{3 c}$, with the atom-labeling scheme, is shown in Figure 3.9.

The $\mathrm{Fe}(\mathrm{II})$ centres are coordinated by two 1,10 -phen nitrogen $(\mathrm{Fe}-\mathrm{N}=$ 2.001(6) and 2.008(6) $\AA$ ) and four cyanide carbon atoms ( $\mathrm{Fe}-\mathrm{C}=1.874(6)$ to $1.929(7) \AA$ ), making a distorted octahedral geometry. The values of the bond lengths and angles involving the $\left[\mathrm{Fe}^{\mathrm{II}}(1,10-\mathrm{phen})(\mathrm{CN})_{4}\right]^{2+}$ fragment are comparable to those observed in the following low-spin $\mathrm{Fe}(\mathrm{II})$ complexes: $\left[\mathrm{Fe}(1,10 \text {-phen })_{2}(\mathrm{CN})_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (Zhuzhong et al., 1996), $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right] \cdot 2.5 \mathrm{H}_{2} \mathrm{O}$ (Nieuwenhuyzen et al., 1998), and $\mathrm{K}_{2}\left[\mathrm{Fe}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (Toma et al., 2002). The $\mathrm{Fe}-\mathrm{C}-\mathrm{N}$ bond angle at the corners of the rectangle are $178.1(6)$ and $177.3(6)^{\circ}$ for the $[\mathrm{Fe} 1-\mathrm{C} 1-\mathrm{N} 1]$ and the [Fe1-C2-N2], respectively. The 1,10-phen ligand exhibits a typical acute $\mathrm{N} \cdots \mathrm{N}$ bite distance of $2.615(7) \AA(\mathrm{N} 5 \cdots \mathrm{~N} 6)$ and bite angle of $81.4(2)^{\circ}(\mathrm{N} 5-\mathrm{Fe} 1-\mathrm{N} 6)$. These are one of the main factors accounting for the distortion from ideal octahedral geometry
$\left(90^{\circ}\right)$. The 1,10 -phen ligand as a whole is close to planar with maximum atomic deviation being $0.033(5) \AA$ at the C 15 . The bond lengths and angles in the 1,10 -phen ligands in $\mathbf{3 c}$ agree well in the mean values of the free 1,10-phen ligand (Tian et al., 1995), and in other 1,10-phen-containing $\mathrm{Fe}(\mathrm{II})$ complex of $\left[\mathrm{FeCl}_{2}(1,10-\mathrm{phen})_{2}\right](\mathrm{Fu}$ et al., 2005).

Figure 3.9 Ball and stick representation of the asymmetric unit in $\mathbf{3 c}$ with numbering scheme and coordination environments of metals centre shown. The labeling scheme, $G-I$, applied to the phenyl rings are used to identity the rings in subsequent discussion. Symmetry code: (i) $-x,-y,-z$.

The $\mathrm{Cu}($ II $)$ centre has an elongated octahedral trans $\left\{\mathrm{CuN}_{4} \mathrm{O}_{2}\right\}$ coordination geometry. The equatorial plane ( $\mathrm{N} 1, \mathrm{~N} 2{ }^{\mathrm{i}}, \mathrm{N} 7$ and N 8 , symmetry code: (i) $-x,-y,-z$ ) is formed by two cyanide nitrogen atoms $\left(\mathrm{Cu} 1-\mathrm{N} 1=1.982(5) \AA\right.$ and $\mathrm{Cu} 1-\mathrm{N} 2^{\mathrm{i}}=$ $1.980(6) \AA$, symmetry codes: (i) $-x,-y,-z$ ) in cis positions and two nitrogen atoms of the chelated tn molecule in the gauche conformation $(\mathrm{Cu} 1-\mathrm{N} 5=2.001(5) \AA$ and $\mathrm{Cu} 1-\mathrm{N} 6=2.008(5) \AA$ ). The $\mathrm{Cu}-\mathrm{N}$ bond lengths in 3 c are comparable to the related complexes of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2}\right] \cdot \mathrm{KCl} \cdot 5 \mathrm{H}_{2} \mathrm{O}(2.004-2.011 \AA)$ and $\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2}\right]$ $\cdot 4 \mathrm{H}_{2} \mathrm{O}(1.987-2.001 \AA)$ (Triki et al., 2006). The axial positions in the octahedron are occupied by two oxygen atoms of aqua ligands showing very long $\mathrm{Cu}-\mathrm{O}$ distances of $2.630(5)$ and $2.470(5) \AA$ for $\mathrm{Cu} 1-\mathrm{O} 1$ and $\mathrm{Cu} 1-\mathrm{O} 2$, respectively. These $\mathrm{Cu}-\mathrm{O}$ values found in $\mathbf{3 c}$ are in the range of semi-coordination (2.22-2.89 $\AA$ ) for $\mathrm{H}_{2} \mathrm{O}$ (Hathaway, 1973) caused by a Jahn-Teller effect. The $\left\{\mathrm{CuN}_{4} \mathrm{O}_{2}\right\}$ geometric parameters of $\mathbf{3 c}$ are comparable with the corresponding values in $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left(\mathrm{S}_{2} \mathrm{O}_{6}\right), \mathrm{Cu}-\mathrm{N}=$ 2.021(2) and $\mathrm{Cu}-\mathrm{O}=2.572(2) \AA(\mathrm{Kim}$ et al., 2003).

The acute angle subtended by the chelated tn ligand at the copper atom in $\mathbf{3 c}$ is $95.0(2)^{\circ}$, comparable to the related bite angle of $94.1^{\circ}$ in $\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right]$ $\cdot \mathrm{KCl} \cdot 5 \mathrm{H}_{2} \mathrm{O}$ (Triki et al., 2006), and slightly larger than that of $89.2^{\circ}$ in $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right.$ $\left.\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left(\mathrm{F}_{2}\right)$ (Emsley and Arif, 1988). The small bite angle causes the deviations from the ideal value of $90^{\circ}$ viz 91.4(2), 87.4(2), 86.1(2), and $95.0(2)^{\circ}$ for $\mathrm{N} 1-\mathrm{Cu} 1-\mathrm{N} 2{ }^{\mathrm{i}}, \mathrm{N} 1-\mathrm{Cu} 1-\mathrm{N} 7, \mathrm{~N} 2^{\mathrm{i}}-\mathrm{Cu} 1-\mathrm{N} 8$, and $\mathrm{N} 7-\mathrm{Cu} 1-\mathrm{N} 8$, respectively (symmetry code: (i) $-x,-y,-z$ ). The $\mathrm{O} 1-\mathrm{Cu} 1-\mathrm{O} 2$ bond angle is $173.4(2)^{\circ}$. $\mathrm{The} \mathrm{Cu}-\mathrm{N}-\mathrm{C}_{\mathrm{CN}}$ bond angles are significant bent at $160.6(5)$ and $160.2(5)^{\circ}$ for $\mathrm{Cu} 1-\mathrm{N} 1-\mathrm{C} 1$ and $\mathrm{Cu} 1-\mathrm{N} 2-\mathrm{C} 2$, respectively. The $\mathrm{Fe}-\mathrm{C}_{\mathrm{CN}}$ bonds in compound 3 c are shorter than the
$\mathrm{Cu}-\mathrm{N}_{\mathrm{CN}}$ bonds, probably due to the stronger $\pi$-back donation from the $\mathrm{Fe}(\mathrm{II})$ ion to the cyanide groups.

The square cores are composed of alternate cyanide-bridged Fe (II) and Cu (II) ions. The four metal atoms occupy the corners and the four cyanide ligands act as edges. The values at the corners of the rectangle are close to right angles $(\mathrm{C} 1-\mathrm{Fe} 1$ $\left.-\mathrm{C} 2=90.6(3)^{\circ}, \mathrm{N} 1-\mathrm{Cu} 1-\mathrm{N} 2=91.4(2)^{\circ}\right)$. The $\mathrm{Fe} \cdots \mathrm{Cu}$ distances along the edges of the rectangles across bridging cyanides are $4.952(1)$ and $4.942(1) \AA$ for $\mathrm{Fe} 1 \cdots \mathrm{Cu} 1$ and Fe1 $\cdots \mathrm{Cu} 1^{\mathrm{i}}$ (symmetry code: (i) $=-x,-y,-z$ ), respectively. The values compare well with those observed in other cyanide-bridged $\mathrm{Fe}-\mathrm{Cu}$ molecular squares complexes, such as $4.983(2)$ and $4.970(2) \AA$ in $\left[\mathrm{Fe}^{\mathrm{II}}{ }_{2} \mathrm{Cu}^{\mathrm{II}}{ }_{2}(\mu-\mathrm{CN})_{4}\left(2,2^{\prime} \text {-bipy }\right)_{6}\right]\left(\mathrm{PF}_{6}\right)_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O} \cdot 3 \mathrm{CHCl}_{3}$ (Oshio et al., 1999), 4.9747(7) and 4.9995(3) $\AA$ in $\left[\mathrm{Fe}^{\mathrm{II}}{ }_{2} \mathrm{Cu}^{\mathrm{II}} 2(\mu-\mathrm{CN})_{4}(\mathrm{dmbpy})_{4}(\mathrm{impy})_{2}\right]$ $\left(\mathrm{ClO}_{4}\right)_{4} \cdot 3 \mathrm{CH}_{3} \mathrm{OH} \cdot \mathrm{C}_{6} \mathrm{H}_{6}$, where dmbpy $=4,4$ '-dimethyl-2,2'-bipyri-dine, impy $=2-(2-$ pyridyl)-4,4,5,5-tetramethyl-4,5-dihydro-1H-imidazolyl-1-oxy (Oshio et al., 2002). These squares have more of the bidentate chelate (on $\mathrm{Fe}^{\mathrm{II}}$ ) and less $\mathrm{CN}^{-}$ligands than in 3c.

An interesting structural feature of $\mathbf{3 c}$ is that the trans coordinated water molecules on the $\mathrm{Cu}(\mathrm{II})$ centres hydrogen bond to neighboring square cores through O 1 and $\mathrm{O} 2(2.832(7) \AA$ ) to give a 1-D tube-like structure along the crystallographic $c$ axis, as shown in Figure 3.10. The closet metal $\cdots$ metal distances between neighboring square cores is $6.699(1) ~ \AA$.

Each coordinated water molecule is hydrogen bonded to three uncoordinated water molecules, with $\mathrm{O} \cdots \mathrm{O}$ distances in the range of $2.779(7)$ to $2.865(13) \AA$. Two of these uncoordinated water molecules (O3 and O4) are also linked to the terminal cyanide nitrogens ( N 3 and N 4 ) of a square core with $\mathrm{O} \cdots \mathrm{N}$ distances between
2.873(7) and 2.958(7) $\AA$. . This is common in hydrated cyanometallates. The remaining uncoordinated water molecules (O5) are further linked to other uncoordinated water molecules (O4) with the $\mathrm{O} \cdots \mathrm{O}$ distances at $2.756(13)$ and $2.865(13) \AA$, forming a 1-D chain along the crystallographic $a$ axis, as shown in Figure 3.11. Weak $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Desiraju and Steiner, 1999) are also observed in this compound. The values of the $\mathrm{D} \cdots \mathrm{A}$ distances are between 3.261(8) and 3.312(7), and 3.398(3) to 3.523(8) $\AA$ for $\mathrm{N} \cdots \mathrm{O}$ and $\mathrm{C} \cdots \mathrm{O}$, respectively.

Figure 3.10 Views of 1-D tube like structure in 3c propagated via hydrogen bonded parallel to the $a$ axis. Hydrogen bonds are represented as dashed green lines.

Furthermore, the structure of compound $\mathbf{3 c}$ showed the presence of $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ bonding interactions which influence the crystal packing. These include $\mathrm{C}-\mathrm{H} \cdots \pi$, interactions involving the carbon atoms (C17 and C18) of the tn ligands and
$\pi$-cloud electrons on the 1,10 -phen moieties (rings $E$ and $F$ ). The values of the $\mathrm{H} \cdots$ centroid $\left(C_{g}\right)$ distances and $\mathrm{C}-\mathrm{H} \cdots C_{g}$ angles are $2.912(6) \AA$ and $129^{\circ}$, and 2.693(7) $\AA$ and $148^{\circ}$, for $\mathrm{C} 17-\mathrm{H} 17 \mathrm{a} \cdots C_{g}(E)$ and $\mathrm{C} 18-\mathrm{H} 18 \mathrm{~b} \cdots C_{g}(F)$, respectively.

Figure 3.11 View of 1-D chain linked via $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds in 3c along the $a$ axis. $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ atoms on 1,10-phen and tn molecules have been omitted for clarity. Hydrogen bonds represented as dashed green lines.

The $\pi \cdots \pi$ type interactions between the 1,10 -phen ligands also contribute to the stabilization the structure of 3c. The 1,10-phen molecules are stacked to each other along the crystallographic $b$ axis, thus leading to 2-D sheets as illustrated in Figure 3.12. The $C_{\mathrm{g}} \cdots C_{\mathrm{g}}$ distances between adjacent 1,10-phen moieties and the dihedral off-set angles are $3.734 \AA$ and $3.1(4)^{\circ}$, and $3.643 \AA$ and $0.0(4)^{\circ}$ for $C_{g}(E) \cdots C_{g}\left(G^{\mathrm{i}}\right)$, and $C_{g}(G) \cdots C_{g}\left(G^{\mathrm{i}}\right)$, respectively (symmetry code: (i) $1+x, y, z$ ). There are additional weak $\mathrm{O} / \mathrm{C}-\mathrm{H} \cdots \pi$ type interactions between the uncoordinated waters or the 1,10 -phen molecules and the mid-point of cyano groups. These interactions help
to enhance the dimensionality into a 3-D supramolecular structure. All relevant interactions in 3c are listed in Tables 3.9 and 3.10.

Figure 3.12 2-D sheet generated through a combination of self-complementary $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds and $\pi-\pi$ interactions. The red and purple cylinders indicate the way to produce pseudo 1-D tubes.

It is interesting to contemplate why the desired square tubes did not form in $\mathbf{3 c}$ since the four CN ligands around $\mathrm{Fe}(\mathrm{II})$ are in correct position as are the $\left\{\mathrm{Fe}^{\mathrm{II}}(1,10-\right.$ phen) $\}$ and $\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}$ ligands (Figure 3.9). Clearly, the $\mathrm{Cu}(\mathrm{II})$ centres "preferred" two trans $\mathrm{H}_{2} \mathrm{O}$ molecules than the nitrogen atom from neighboring $\left[\mathrm{Fe}^{\mathrm{II}}(1,10-\right.$ phen $\left.)(\mathrm{CN})_{4}\right]^{2-}$ groups. Perhaps dry organic solvents and organic soluble metal precursors are the way to go in the future.

### 3.3.5 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2}, \mathbf{2}^{\prime}-\mathrm{bipy}\right)(\mathbf{C N})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathbf{H}_{\mathbf{2}} \mathrm{O}$ (3d)

A 1:1:1 molar ratio of $\left[\mathrm{Fe}^{\text {II }}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4}\right], \mathrm{Cu}\left(\mathrm{ClO}_{4}\right) \cdot \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and th was reacted to give brown-red needles of 3d. The microanalysis of this crystalline product is consistent with the $\mathrm{C}, \mathrm{H}$ and N values expected for the formula $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O}$. Despite the poor quality of the crystals, a data set was obtained that only to unambiguously establish the molecular square. Thus, only the molecular geometry or at least the bond connectivities are described. The bond lengths and angles as well as supramolecular interactions are not discussed here.

The unit cell parameters $a, b$ and $c$ are very similar, and the space group is identical to that in $\mathbf{3 c}$. The structure of $\mathbf{3 d}$ is made up of neutral tetranuclear molecular rectangles of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4} \mathrm{Cu}^{\text {II }}(\mathrm{tn})\right]$. The connectivity of the square core in $\mathbf{3 d}$ is essentially the same to that of $\mathbf{3 c}$, which consists of cyanide-bridged Fe (II) and $\mathrm{Cu}(\mathrm{II})$ centrosymmetric rectangles, as shown in Figure 3.13. Again, each Fe(II) centre exhibits a distorted octahedral geometry with two pyridyl nitrogen atoms from a $2,2^{\prime}-$ bipy ligand and four carbon atoms from the cyanide ligands.

Unlike in compound $\mathbf{3 c}$, the $\mathrm{Cu}(\mathrm{II})$ ions have a distorted square-planar geometry (pseudotetrahedral), and are coordinated by four nitrogen atoms: two from chelated tn N -donor ligands, and another two nitrogen atoms from two bridging
cyanide groups. Intriguingly and frustratingly, it is likely that this "out-of-plane" geometry around each $\mathrm{Cu}(\mathrm{II})$ prevents extension into square tube motifs, via $\mathrm{N}-\mathrm{C}-\mathrm{Fe}$ bridging to the next squares since bonded water is absent in 3d.

Figure 3.13 Ball and stick representation showing the atom connectivity and coordination environment in 3d.

### 3.3.6 Structural Description of $\left[\mathrm{Fe}^{\text {II }}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Ni}^{\text {II }}(\mathrm{en})_{2}\right]$-Solvent (3e)

Single crystal X-ray analysis at $123(2) \mathrm{K}$ reveals that 3e crystallizes in the monoclinic system with space group $P 2_{1} / n$ (No. 14). The asymmetric unit consists of one $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ anion, one cis- $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right]^{2+}$ cation, and disordered clathrated solvent molecules as shown in Figure 3.14. Each of metal (II) centres lies on a general position. Since the mono-chelated precursor $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ was used in synthesis, a rearrangement to the bis complex $\left[\mathrm{Ni}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ has occurred during reaction and crystallization, in low yield, of product $\mathbf{3 e}$.

Figure 3.14 Thermal ellipsoid plot at the 50\% probability level of 3e containing coordination environments of metals centre shown. Disordered solvent molecules and hydrogen atoms are omitted. The labeling scheme, $J-K$, applied to the phenyl rings is used to identify the rings in subsequent discussion. Symmetry code: (i) $-1+x, y, z$.

The Fe(II) ions are coordinated by two $2,2^{\prime}$-bipy nitrogen atoms and four cyanide carbon atoms, taking a distorted octahedral geometry. The bond lengths and angles around the $\mathrm{Fe}(\mathrm{II})$ centres in $\mathbf{3 e}$ are comparable to those found in $\mathbf{3 a} \mathbf{- 3}$. The 2,2'-bipy ligand as a whole is close to planar. The mean deviation from the best plane calculated using all twelve atoms is $0.067 \AA$ with the largest deviation being $-0.105(5) \AA$ at C13. The bond lengths and angles within the $2,2^{\prime}$-bipy group compare well with those reported for the free $2,2^{\prime}$-bipy molecule (Merritt and Schroeder, 1956). The small bite angle of the bidentate $2,2^{\prime}$-bipy ligand is $80.4(1)^{\circ}$ for N5-Fe1-N6. This factor accounts for the distorted octahedral geometry of the Fe(II) centre from the ideal geometry $\left(90^{\circ}\right)$.

The $\mathrm{Ni}(\mathrm{II})$ centre exists in a distorted octahedral geometry defined by six nitrogen atoms. The equatorial positions are occupied by three nitrogen atoms of two en ligands (N7, N8, N9) and a cyano nitrogen atom (N1), whereas the nitrogen atom of one en ligand ( N 10 ) and a cyano nitrogen atom ( $\mathrm{N} 2^{\mathrm{i}} ;(\mathrm{i})=-x, y-1 / 2, z-1 / 2$ ) occupy the apical sites. The average $\mathrm{Ni}-\mathrm{N}_{\text {en }}$ bond length is $2.113 \AA$, which agrees with those observed in the bis- $\left\{\mathrm{Ni}^{\text {II }}(\mathrm{en})\right\}$ complex such as $\left[\mathrm{Ni}(\mathrm{en})_{2}(\mathrm{py})_{2}\right]\left(\mathrm{NO}_{3}\right)_{2}$ (Baldwin et al., 1999). The average $\mathrm{Ni}-\mathrm{N}_{\mathrm{CN}}$ bond is $2.075 \AA$, which is slightly shorter than those of the $\mathrm{Ni}-\mathrm{N}_{\mathrm{en}}$ lengths. However, similar lengthening of the $\mathrm{Ni}-\mathrm{N}_{\mathrm{en}}$ bonds versus the $\mathrm{Ni}-\mathrm{N}_{\mathrm{CN}}$ bonds was observed in $\left[\left\{\mathrm{M}^{\mathrm{III}}(\mathrm{CN})_{6}\right\}_{2}\left\{\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right\}_{3}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{M}^{\mathrm{III}}=\mathrm{Mn}$, $\mathrm{Fe}, \mathrm{Co}$, and Cr (Ohba et al., 1997). The maximum deviation from the ideal octahedral geometry of the nickel centre is manifested in the angle variation from $90^{\circ}$ to 84.8(2) and $95.2(2)^{\circ}$ of the $\mathrm{N} 1-\mathrm{Ni}-\mathrm{N} 10$ and $\mathrm{N} 1-\mathrm{Ni}-\mathrm{N} 2$ angles, respectively, and the reduction from $180^{\circ}$ for $\mathrm{N} 1-\mathrm{Ni} 1-\mathrm{N} 8$ to $170.6(2)^{\circ}$.

The structure of $\mathbf{3 e}$ consists of infinite 1-D zigzag bimetallic chains parallel to the $b$ axis as shown in Figure 3.15. Within the chain, each $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4}\right]^{2-}$ unit connects to two cis- $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right]^{2+}$ moieties through two cyanide ions ( C 1 N 1 and C2N2) in the cis position, whereas the other two cyano groups (C3N3 and C4N4) remain terminal. The adjacent $\mathrm{Fe} \cdots \mathrm{Ni}$ separations across the cyanide groups are 4.814(1) and $4.959(1) \AA$ for Fel $\cdots$ Nil and $\mathrm{Fe} 1 \cdots \mathrm{Nil}^{\mathrm{i}}$ (symmetry code: $\mathrm{i}=-x, y+1 / 2$, $-z+1 / 2)$, respectively. The nearest interchain metal $\cdots$ metal distances are 8.494(1) and 6.064(1) $\AA$ for the $\mathrm{Fe} 1 \cdots \mathrm{Fe}^{\mathrm{i}}$ (symmetry code: $\mathrm{i}=-x, y-1 / 2,-z+1 / 2$ ) and the $\mathrm{Ni} 1 \cdots \mathrm{Ni} 1^{\mathrm{ii}}$ (symmetry code: $\mathrm{ii}=-x, y+1 / 2,-z+1 / 2$ ), respectively. The linkage of cyanide-bridges in the cis position in a complex cation into zigzag chain as in $\mathbf{3 e}$ was also observed in the structure of $\left[\left\{\mathrm{Fe}^{\mathrm{III}}(\mathrm{CN})_{6}\right\}_{2}\left\{\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right\}_{3}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Ohba et al., 1994).

Intermolecular $\pi \cdots \pi$ interactions are a feature commonly observed in many compounds containing chelating aromatic planar molecules (Janiak, 2000). For 3e, the shortest interplanar $2,2^{\prime}$-bipy $\cdots 2,2^{\prime}$-bipy separation is $3.553(7) \AA\left(C_{g}(H) \cdots C_{g}(I)\right.$ distances at $4.156 \AA$ ) with the dihedral angle between the planes being $0.0(2)$, indicating the existence of $\pi \cdots \pi$ interactions. $\mathrm{N}-\mathrm{H} \cdots \pi$ (ring $I$ ) interactions involving the bis-chelating en ligands and 2,2'-bipy moieties are also observed. The values of the $\mathrm{H} \cdots \pi$ distances and $\mathrm{N}-\mathrm{H} \cdots \pi$ angles are 2.835(6) and 2.918(7) $\AA$, and 111.3 and $113.8^{\circ}$, respectively. Relatively weak intermolecular $\mathrm{C}-\mathrm{H} \cdots \pi(\mathrm{C} \equiv \mathrm{N})$ hydrogen bonding occurs between amine protons and $\pi$-acceptor sites on adjacent cyanide groups.

Figure 3.15 View of the 1-D zigzag chains in 3e running parallel to the $b$ axis. Intermolecular $\pi-\pi$ contacts represented by dotted green lines are observed between the $2,2^{\prime}$-bipy ligands of adjacent chains.

Furthermore, there is also extensive hydrogen bonds between the 1-D polymeric zigzag chains involving the clathrated solvent molecules and the terminal cyanide group of the $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ unit. Unfortunately, due to the high disorder in the intercalated solvent molecules, the positions of the atoms are very difficult to model. Therefore, the interactions are not discussed in detail. However, these interactions likely exist between the chains thus linking them into a novel 3-D supramolecular architecture as shown in Figure 3.16.

Figure 3.16 Stacking of four consecutive $\mathrm{Fe}^{\mathrm{II}}-\mathrm{Ni}^{\mathrm{II}}$ bimetallic chains of $\mathbf{3 e}$ along the $c$ axis. Included solvent is represented by the space filling models.

Magnetic measurements were made with the sample dispersed in Vaseline to eliminate field induced torquing of the crystallites (Kennedy and Murray, 1985). Typically, samples were ground with Vaseline, and a uniform mull was prepared. Measurements were made with both increasing and decreasing magnetic fields. The mass of the sample contained within the Vaseline mulls was determined by comparing the gram susceptibility of the neat crystalline with that of the mull, once corrections for the diamagnetic sample holder and Vaseline had been made, over a temperature range of not less than 30 K .

### 3.3.7 Magnetic Properties of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathbf{C N})_{4} \mathbf{M n}{ }^{\mathrm{II}}\right] \cdot \mathrm{MeOH}$ (3a)

The variable temperature magnetic susceptibility data of polycrystalline 3a was measured in the $2-300 \mathrm{~K}$ temperature range under an applied field of 1 T . Plots of magnetic behaviours in 3a are shown in Figure 3.17, in the form of effective magnetic moment ( $\mu_{\text {eff }}$ ) per $2 \mathrm{Mn}^{\mathrm{II}}$ and $2 \mathrm{Fe}^{\mathrm{II}}$, versus the temperature. In accordance with the $1 / \chi_{\mathrm{M}}$ vs $T$ plot, in the range $2-300 \mathrm{~K}$, 3a obey a Curie-Weiss $S=5 / 2$ susceptibility behaviour with a positive Weiss constant of $\theta=0.72 \mathrm{~K}$, indicating the presence of a ferromagnetic interaction, and $C=7.93 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$. The room temperature $\mu_{\text {eff }}$ value of $8.01 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=8.02 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $\mathbf{3 a}$ is slightly lower than the spin-only value of $8.37 \mu_{\mathrm{B}}$ expected for a magnetically dilute spin system with two $\mathrm{Fe}^{\mathrm{II}}(S=0)$ and two $\mathrm{Mn}^{\text {II }}$ ions $(S=5 / 2)$, calculated for $g=2.00$. As the temperature is decreased from 300 to $c a .50 \mathrm{~K}$, the $\mu_{\text {eff }}$ values remain virtually constant then gradually increase, then abruptly to reach a maximum value of $9.53 \mu_{\mathrm{B}}$ $\left(\chi_{\mathrm{M}} T=11.35 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ at $c a .4 \mathrm{~K}$, and finally decreases sharply to $8.47 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=\right.$ $8.97 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ ) at 2 K . This behavior is suggestive of either ferromagnetic coupling between the nearest neighbor high-spin $\mathrm{Mn}^{\mathrm{II}}\left(\mathrm{t}_{2 \mathrm{~g}}^{3} \mathrm{e}_{\mathrm{g}}^{2}\right)$ ions separated by $c a .6 .5 \AA$
through the $\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}-\mathrm{CN}$ pathways containing diamagnetic $\mathrm{Fe}^{\mathrm{II}}\left(\mathrm{t}_{2 \mathrm{~g}}^{6} \mathrm{e}_{\mathrm{g}}^{0}\right)$ centres, or via the non-covalent interactions (i.e. hydrogen bonding and $\pi-\pi$ interactions), which is somewhat similar to that observed in the haptanuclear [\{ $\left.\mathrm{Mn}^{\mathrm{II}}(\mathrm{dmptacn}) \mathrm{CN}\right\}_{6}$ $\left.\mathrm{Fe}^{\mathrm{II}}\right]\left(\mathrm{ClO}_{4}\right)_{8} \cdot 5 \mathrm{H}_{2} \mathrm{O}$, where dmptacn $=$ 1,4-bis(2-pyridylmethyl)-1,4,7-triazacyclononane (Parker et al., 2002). There are no such weak interactions connecting the $\mathrm{Mn}(\mathrm{II})$ centres directly, so the bridging via $\left\{\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{2}\right\}$ is more likely.

Figure 3.17 Plot of magnetic moment, per $2\left[\mathrm{Mn}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$, in fields of $0.01,0.1$ and 1 T for $\mathbf{3 a}$. The $2-30 \mathrm{~K}$ region is expanded in the insert. The solid lines are not calculated plots.

When small fields of 0.01 and 0.1 T are applied (insert of Figure), there is a rapid increase in the magnetic moment below 10 K , reaching a higher value at 2 K of
ca. $15.95 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=31.80 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ and $15.58 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=30.30 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for 0.01 and 0.1 T fields, respectively. This field dependent behavior is suggesting of low lying Zeeman levels showing different thermal population as temperature varies, perhaps with saturation at higher field.

To further explore the origin of the ferromagnetic nature of the $\mathrm{Mn}^{\mathrm{II}} \ldots \mathrm{Mn}^{\mathrm{II}}$ interaction, and indentify the coupled ground state, the magnetic field, $H$, dependence of DC magnetization ( $M$ ) was investigated at various temperatures of $2,3,4,5.5,10$ and 20 K , with magnetic fields up to 50000 Oe ( $0-5 \mathrm{~T}$ ) using a SQUID magnetometer. The resulting magnetization isotherms for 3a are shown in Figure 3.18, where the molar magnetization $M$ is expressed in $\mu_{\mathrm{B}}(\mathrm{N} \beta)$ units, and $M$ is expected to have the saturation value $M s$, when $H / k T$ becomes very large, according to the equation of $M s=N g \mu_{\mathrm{B}} S$. In such a case the $\mathrm{Mn}^{\mathrm{II}}$ single ion ground state is $S=$ $5 / 2$ and the magnetization (per $2 \mathrm{Mn}^{\mathrm{II}}$ unit) should saturate to the value of $M=10 \mu_{\mathrm{B}}$ for two ferromagnetically coupled $\mathrm{Mn}^{\mathrm{II}}$ ions, $S_{\text {TOTAL }}=10 / 2$. Experimental data have shown that with the temperature at $T=2.0 \mathrm{~K}$, the magnetization adopts a value of $M=$ $10.0 \mathrm{~N} \mu_{\mathrm{B}}$, which is very close to the theoretical value, and appears to be approaching saturation at the magnetic field $H=50000$ Oe. No long-range ordering or slow relaxation of the magnetization in 3a was observed above 2 K evidenced by measurement of $M$ in zero field (ZFCM) or in very small ( $\sim 10 \mathrm{Oe}$ ) field cooling (FCM); the plots were identical (similar to Figure 3.21). Thus the repeat units $\mathrm{Fe}_{2} \mathrm{Mn}_{2}$ in Figure 3.1 show ferromagnetic coupling between $\mathrm{Mn}^{\text {II }}$ ions. The calculated magnetic moment value for a $S=10 / 2$ level is $10.95 \mu_{\mathrm{B}}$, this correspond to $c a .15 .70$ $\mu_{\mathrm{B}}$ observed in 0.01 and 0.1 T fields (Figure 3.17).

Figure 3.18 The DC magnetization isotherms ( $0-5 \mathrm{~T}$ ) for 3a, per $\mathrm{Fe}_{2}^{\mathrm{II}} \mathrm{Mn}_{2}^{\mathrm{II}}$.

### 3.3.8 Magnetic Properties of $\left[\mathrm{Fe}^{\text {II }}\left(\mathbf{2}, \mathbf{2}^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3b)

The magnetic moments for $\mathbf{3 b}$ were measured in the $2-300 \mathrm{~K}$ temperature range under an applied field of 1 T , and the plots of $\mu_{\text {eff }}$ vs $T$, per $\mathrm{Fe}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{II}}$, are given in Figure 3.19. In accordance with ferromagnetism, the $1 / \chi_{\mathrm{M}}$ vs $T$ plot, in the range $2-300 \mathrm{~K}$, obeys the Curie-Weiss law with a positive Weiss constant of $\Theta=1.38 \mathrm{~K}$, and $C=4.36 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$. The $\mu_{\text {eff }}$ at room temperature, $5.93 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=4.39 \mathrm{~cm}^{3}\right.$ $\mathrm{mol}^{-1} \mathrm{~K}$ ), agrees with the spin-only value of $5.92 \mu_{\mathrm{B}}$ expected for the magnetically dilute spin system with low-spin $\mathrm{Fe}^{\mathrm{II}}(S=0)$ and high-spin $\mathrm{Mn}^{\mathrm{II}}$ ions $(S=5 / 2)$, assuming $g=2.00$. Similar to the magnetic behavior observed in 3a, on lowering the temperature, the $\mu_{\text {eff }}$ values remain constant between $300-50 \mathrm{~K}$ and gradually increase, then abruptly to reach a maximum value of $6.70 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=5.61 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}\right.$
K) at $c a .4 \mathrm{~K}$, and finally decreases sharply to $6.00 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=4.50 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ at 2 K. This behavior is similar to that observed in 3a, suggesting a ferromagnetic coupling interaction between the nearest high-spin $\mathrm{Mn}^{\mathrm{II}}$ ions through the low-spin $\mathrm{Fe}^{\mathrm{II}}$ ions via bridging CN groups of the 1-D tube structure. This is more likely than via the non-covalent interactions (i.e. hydrogen bonding and $\pi-\pi$ interactions) between the $1-$ D tubes.

Figure 3.19 Plot of magnetic moment, per [ $\left.\mathrm{Mn}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$, in fields of $0.01,0.1$ and 1 T for 3b. The $2-30 \mathrm{~K}$ region is expanded in the insert. The solid lines are not calculated plots.

As the applied field was decreased to values of 0.1 and 0.01 T , the $\mu_{\text {eff }}$ values increased rapidly below 10 K reaching a larger value of $c a .10 .10 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=12.75\right.$
$\mathrm{cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ ) for both the 0.01 and 0.1 T fields at 2 K (insert of figure). For two ferromagnetically coupled $S=5 / 2\left(\mathrm{Mn}^{\mathrm{II}}\right)$ ions, the $S=10 / 2$ state should yield $\mu_{\mathrm{eff}} \approx$ $10.90 \mu_{\text {B }}$ per $2\left\{\mathrm{Fe}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{II}}\right\}$, i.e. $7.5 \mu_{\mathrm{B}}$ per $\left\{\mathrm{Fe}^{\mathrm{II}} \mathrm{Mn}^{\mathrm{II}}\right\}$ lower than observed at the maximum for 1 T and lower than the 2 K values in the smaller fields.

Figure 3.20 The DC magnetization isotherms ( $0-5 \mathrm{~T}$ ) for $\mathbf{3 b}$, per $\left[\mathrm{Mn}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$.

Further, probing of the the low temperature region by measurements of magnetisation (M) isotherms (2-20 K) of 3b yielded the plots shown in Figure 3.20. At 50000 Oe and 2 K , the magnetization, per $\left[\mathrm{Mn}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$, is nearly saturated with a value of $5.30 \mu_{\mathrm{B}}$. The calculated saturation magnetization (Ms) for a spin-only system consisting of ferromagnetically coupled high-spin $\mathrm{Mn}^{\mathrm{II}}$ ions ( $S=5 / 2$ ), assuming $g=$ 2.00, is $10.0 \mu_{\mathrm{B}}$ per $\mathrm{Mn}_{2}$, i.e. $5.0 \mu_{\mathrm{B}}$ per Mn . Measurement of FCM and ZFCM show identical behaviour at temperatures $4-35 \mathrm{~K}$ as shown in Figure 3.21, indicating no
magnetic ordering occurs in the crystalline samaple of $\mathbf{3 b}$. If ordering occurred the two curves would diverge at the $T_{\mathrm{C}}$ temperature. Thus, as in 3a, ferromagnetic coupling occure in 3b between nearest $\mathrm{Mn}^{\mathrm{II}}$ centers. There might be very weak tube-tube interactions.

Figure 3.21 Temperature dependence ( $4-35 \mathrm{~K}$ ) of FCM and ZFCM for $\mathbf{3 b}$, in emu units from the SQUID instrument.

### 3.3.9 Magnetic Properties of the Molecular Squares [Fe ${ }^{\text {II }}(1,10-\mathrm{phen})(\mathbf{C N})_{4}$ $\left.\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot \mathbf{5} \mathrm{H}_{2} \mathrm{O}(\mathbf{3 c})$ and $\left[\mathrm{Fe}^{\mathrm{II}}\left(\mathbf{2}, 2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN}) \mathbf{4}_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathbf{H}_{2} \mathrm{O}(\mathbf{3 d})$

The magnetic susceptibilities of polycrystalline samples of $\mathbf{3 c}$ and $\mathbf{3 d}$ were measured as a function of temperature in the range of $2-300 \mathrm{~K}$ under an applied field of 1 T . The plots of the form of the effective magnetic moment ( $\mu_{\text {eff }}$ ) per $\left[\mathrm{Cu}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$
unit, versus the temperature for $\mathbf{3 c}$ and $\mathbf{3 d}$ are given in Figure 3.22. The magnetic properties of 3c and 3d are generally similar and behave essentially as two isolated paramagnetic $\mathrm{Cu}(\mathrm{II})$ centres with perhaps very weak antiferromagnetic coupling occurring between the $\mathrm{d}^{9} \mathrm{Cu}^{\text {II }}(S=1 / 2)$ centers through the diamagnetic $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4}\right]^{2-}, \mathrm{d}^{6} \mathrm{Fe}^{\text {II }}(S=0)$ centers. The values of $\mu_{\text {eff }}$ at 300 K are $2.02 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=\right.$ $\left.0.51 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $3 \mathbf{c}$ and $1.78 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=0.40 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for 3 d . As the temperature decreases, the $\mu_{\text {eff }}$ values for the compounds remain almost constant until ca. 40 K , then decreases gradually in the $40-15 \mathrm{~K}$ range, and finally decreases sharply to reach ca. $1.05 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=0.10 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $\mathbf{3 c}$, and $1.05 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=0.14 \mathrm{~cm}^{3}\right.$ $\mathrm{mol}^{-1} \mathrm{~K}$ ) for 3 d at 2 K . The $1 / \chi_{\mathrm{M}}$ versus $T$ plots obey the Curie-Weiss law, $\chi_{\mathrm{M}}=$ $C /(T-\Theta), C=0.52$ and $0.35 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$, with a negative Weiss constant $(\Theta)=-2.25$ and -4.27 K for $\mathbf{3 c}$ and $\mathbf{3 d}$, respectively. No differences between the magnetization (M) in zero-field cooling (ZFCM) and in field-cooling (FCM) samples are observed down to 2 K for both compounds, which indicates that no long-range magnetic ordering occurs, at least above 2 K .

The weak intra-square antiferromagnetic coupling is not surprising since the long $\mathrm{Cu}^{\mathrm{II}}(S=1 / 2)-\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}(S=0)-\mathrm{CN}-\mathrm{Cu}^{\mathrm{II}}(S=1 / 2)$ pathway will lead to very weak coupling. The $\mathrm{Cu}^{\mathrm{II}}(S=1 / 2) \cdots \mathrm{Cu}^{\mathrm{II}}(S=1 / 2)$ distances, through the long diamagnetic $\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}-\mathrm{CN}$ bridge (the empty $\mathrm{d}_{\sigma}$ orbital of the $\mathrm{Fe}^{\mathrm{II}}$ ion), in both compounds are $c a$. $10 \AA$. The magnetic behaviour of $\mathbf{3 c}$ and $\mathbf{3 d}$ are also similar to those observed in the compounds $\quad\left[\left\{\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right\}_{2} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O} \quad$ and $\quad\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tnH})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2} \mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Triki et al., 2006).

Figure 3.22 Plot of magnetic moment, per $\left[\mathrm{Cu}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$ for $\mathbf{3 c} \mathbf{- 3 d}$, and per $\left[\mathrm{Ni}^{\mathrm{II}} \mathrm{Fe}^{\mathrm{II}}\right]$ for 3e. The solid lines are not calculated plots.

### 3.3.10 Magnetic Properties of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.\left.)(\mathbf{C N})_{4} \mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right\}\right] \cdot$ Solvent (3e)

Variable temperature magnetic susceptibility data for a polycrystalline sample of $\mathbf{3 e}$ were collected in the temperature range $2-300 \mathrm{~K}$, in the form of $\mu_{\text {eff }} \mathrm{vs} T$, per [ $\mathrm{Fe}^{\mathrm{II}} \mathrm{Ni}^{\mathrm{II}}$ ] unit, (Figure 3.22). Again, due to the diamagnetic nature of the $\mathrm{d}^{6} \mathrm{Fe}^{\mathrm{II}}(S=$ 0 ) centres, while $\mathrm{Ni}^{\text {II }}$ has a $\mathrm{d}^{8}$ configuration $(S=1)$, the magnetic data in $\mathbf{3 e}$ is therefore caused by the $\mathrm{Ni}^{\mathrm{II}}$ ions. The $\mu_{\text {eff }}$ at room temperature of $\mathbf{3 e}$ is $3.08 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=\right.$ $1.10 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$ ), which is typical of $\mathrm{Ni}^{\mathrm{II}}$ ions. The $\mu_{\text {eff }}$ values for 3 e are practically independent of temperature in the range $300-50 \mathrm{~K}$, then decreases gradually, and finally decreased sharply to reach $2.76 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=0.95 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $\mathbf{3 c}$ at 2 K . The $1 / \chi_{\mathrm{M}}$ versus $T$ plots obeys the Curie-Weiss law, $\chi_{\mathrm{M}}=C /(T-\Theta), C=1.13 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$, with a negative Weiss constant $(\Theta)=-1.74$, respectively. The successive decrease of
$\chi_{\mathrm{M}}$ and the negative $\Theta$ value suggest the operation of weak antiferromagnetic interaction between $\mathrm{Ni}^{\mathrm{II}}$ ions through the diamagnetic $-\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}-\mathrm{CN}-$ bridges
 behaviour to that found in $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{6}\left\{\mathrm{Ni}^{\mathrm{II}}(\mathrm{L})_{2}\right\}_{3}\right] \mathrm{X}_{2}$, where $\mathrm{L}=$ 1,2-ethylenediamine, trimethylenediamine, $\mathrm{X}=\mathrm{PF}_{6}^{-}, \mathrm{ClO}_{4}^{-}$(Fukita et al., 1998) and $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{dmptacn})\right.$ $\left.(\mathrm{CN})_{6} \mathrm{Fe}^{\mathrm{II}}\right]\left(\mathrm{ClO}_{4}\right)_{8} \cdot 7 \mathrm{H}_{2} \mathrm{O}$, where dmptacn $=$ 1,4-bis(2-pyridylmethyl)-1,4,7-triazacyclononane (Parker et al., 2002), which all display weak ferromagnetic coupling via $\mathrm{Ni}^{\mathrm{II}}-\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}-\mathrm{CN}-\mathrm{Ni}^{\mathrm{II}}$ pathways.

### 3.4 Conclusions and Future Prospects

This study began with the rational design of making some new cyanidebridged bimetallic materials having 1-D square tube motifs using a tetracyanoferrate of the formula $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4}\right]^{x-}$, where $\mathrm{L}=1,10$-phen, $2,2^{\prime}$-bipy, en, $\mathrm{tn} ; x=1$ or 2 , as building blocks. These ionic species were reacted with $\left[\mathrm{M}(\mathrm{L})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ where $\mathrm{L}^{\prime}=\mathrm{en}$, tn, and while the desired square-tubes of the stoichiometry $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4} \mathrm{M}\left(\mathrm{L}^{\prime}\right)\right]$ have not been isolated, five new cyanide-bridged bimetallic compounds have been synthesized and characterized. Two of these are coordination polymers, one with a 2D corrugated $(4,4)$ sheets structure, of formula $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\right] \cdot \mathrm{MeOH}$ (3a), the other with a 1-D hexagonal tube-like structure, of formula $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $)$ $\left.(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3b). These materials were reproducibly synthesized via the selfassembly reactions of the $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{Fe}^{\mathrm{III}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right]^{-}$ building blocks respectively with $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ in aqueous methanolic solution, respectively. Surprisingly, the synthetic process for $\mathbf{3 b}$ involves the spontaneous reduction of the paramagnetic $\left[\mathrm{Fe}^{\text {III }}\left(2,2^{\prime}-\mathrm{bipy}\right)(\mathrm{CN})_{4}\right]^{-}$ion into the diamagnetic
$\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime} \text {-bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ ion. Both compounds display similar ferromagnetic coupling between $\mathrm{Mn}^{\mathrm{II}}$ ions. The ferromagnetic coupling probably arises because of the ca. $90^{\circ}$ angle across the $\mathrm{Mn}^{\mathrm{II}}-\mathrm{NC}-\mathrm{Fe}^{\mathrm{II}}-\mathrm{CN}-\mathrm{Mn}^{\mathrm{II}}$ bridge at the corners of the squares. No long-range magnetic ordering occurs over the lattice down to 2 K owing to the diamagnetic nature of the $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ bridges combined with the weak intra-tube and tube-tube interactions in the case of $\mathbf{3 b}$.

Reactions of the $\left[\mathrm{Fe}^{\mathrm{II}}(1,10-\text { phen })(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ building blocks with the $\left[\mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$ cation in water reproducibly afforded single crystals of new examples of cyanide-bridged $\mathrm{Fe}_{2}^{\mathrm{II}}-\mathrm{Cu}_{2}^{\mathrm{II}}$ molecular squares, of formulae $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 5 \mathrm{H}_{2} \mathrm{O} \quad(\mathbf{3 c})$ and $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{CN})_{4} \mathrm{Cu}^{\mathrm{II}}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \quad(\mathbf{3 d})$. Even though each has the correct square geometry to form a square tube, they do not. An interesting structure of $\mathbf{3 c}$ is that each square core is propagated by supramolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds feature, into 1-D tube-like structure along the crystallographic $c$ axis. Magnetic studies for 3c and 3d reveal a very weak antiferromagnetic exchange interaction (close to paramagnetism) between nearest $\mathrm{Cu}^{\text {II }}$ ions through the diamagnetic cyano- $\mathrm{Fe}^{\mathrm{II}}$ ion, and again, no magnetic ordering occurs over the lattice down to 2 K .

In the last compound of formula $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)(\mathrm{CN})_{4} \mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\right] \cdot$ solvent (3e) was obtained from the slow diffusion reaction of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}-\text { bipy }\right)(\mathrm{CN})_{4}\right]^{2-}$ with $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ in aqueous methanolic solution. The $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{2+}$ had rearranged to the $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$ form. 3e shows a structure involving 1-D zigzag bimetallic chains that run parallel to the crystallographic $b$ axis. This compound exhibits a weak antiferromagnetic intrachain interaction between the paramagnetic $\mathrm{Ni}(\mathrm{II})$ centers with no long-range magnetic ordering occurring. Thus, while the
desired square tubes have not been achieved, some beautiful CN -bridged bimetallic have been isolated, some with other tube motifs.

In future work, from the topological point of view, the $\mathrm{Mn}^{\mathrm{II}}$ ions of the 1-D tube-like structure of $\left[\mathrm{Fe}^{\mathrm{II}}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}^{\mathrm{II}}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ (3b), could possibly be replaced by the other octahedral transition metal centres. In particular, the replacement of $\mathrm{Mn}^{\text {II }}$ by $\mathrm{Fe}^{\text {II }}$ ion, would offer an opportunity to achieve multifunctional materials involving spin-crossover (at the $\left\{\mathrm{Fe}^{\mathrm{II}}(\mathrm{N})_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right\}$ centres) perhaps with porosity. To obtain the original target compounds $\left[\mathrm{Fe}(\mathrm{L})(\mathrm{CN})_{4} \mathrm{M}\left(\mathrm{L}^{\prime}\right)\right]$, the bonding of $\mathrm{H}_{2} \mathrm{O}$ at $\mathrm{M}=\mathrm{Cu}^{\text {II }}$ (in 3c) mean that dry solvent condition, and anhydrous precursor materials will need to be used. The projection of the th ligand above the $\left\{\mathrm{Cu}_{2} \mathrm{Fe}_{2}\right\}$ square plane in 3d mean that en ligand should be tried.

Due to the diamagnetic nature of the $\left[\mathrm{Fe}^{\mathrm{II}}(\text { bidentate })(\mathrm{CN})_{4}\right]^{2-}$ building block, the substitution of the diamagnetic $\mathrm{Fe}^{\mathrm{II}}$ ion $(S=0)$ for a paramagnetic $\mathrm{M}^{\mathrm{III}}$ ion, such as $\mathrm{Fe}^{\text {III }}(S=1 / 2), \mathrm{Cr}^{\text {III }}(S=3 / 2)$ or $\mathrm{Ru}^{\text {III }}(S=1 / 2)$, is of great interest in achieving stronger exchange coupling and long-range magnetic ordering over the 3-D lattice. The $\left[\mathrm{M}(\right.$ bidentate $\left.)(\mathrm{CN})_{4}\right]$ building blocks have important implications also in developing future designs of novel cyanide-bridged supramolecular coordination compounds of the single-molecule magnet, SMMs (George et al., 2000; Gatteschi and Sessoli, 2003; Beltran, and Long, 2005) or single-chain magnet, SCM (Lescouězec et al., 2005).

## CHAPTER IV

## SUPRAMOLECULAR ARCHITECTURE

## AND COORDINATION POLYMERS WITH $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$ AS BUILDING BLOCK

### 4.1 Introduction

The crystal engineering of supramolecular architectures or metal organic coordination polymers has attracted great attention due to their potential use as functional solid materials (Robson et al., 1992; Batten and Robson, 1998, Yaghi et al., 2003). But, in many cases, it is quite difficult to control the desired solid state structures. Several factors such as (i) stereo electronic molecular information encoded in the ligands, (ii) size, charge and electronic structure, and (iii) external conditions, eg. solvent, counter ions, have a strong influence in the crystallization process on the formation of the solid state architectures. It is well known that noncovalent interactions (eg. hydrogen bonds, $\pi-\pi$ and metallophilic interactions) have also presented a synthetic paradigm for the rational design and synthesis of functional materials in supramolecular chemistry (Desiraju, 2003).

The linear dicyanometallates of formula $\left[\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right]^{-}$, where $\mathrm{M}^{\mathrm{I}}=\mathrm{Ag}$ and Au , are of particular interest for use as bridging ligands for the construction of multidimensional cyanometalate coordination polymers exhibiting spin-crossover (SCO) phenomena (Niel et al., 2002, Niel et al., 2003; Niel et al., 2005; Munoz et al., 2007). These complex ligands have show versatile abilities to coordinate to metal ions
in different modes and numbers such as the (i) rod-shaped or a linear bridging motif (Dong et al., 2003), (ii) a discrete anion playing the role of space filler (Omary et al., 1996), and (iii) as a unidentate ligand blocking some coordination sites of a central atom (Soma and Iwamoto, 1998). Unlike other related two-connecting bridging ligands such as dicyanamide, $\left[\mathrm{N}(\mathrm{CN})_{2}\right]^{-}$, the $\left[\mathrm{M}(\mathrm{CN})_{2}\right]^{-}$bridges can also possesses the ability to further stabilize the polymeric structures through interactions between closed-shell $\mathrm{d}^{10} \cdots \mathrm{~d}^{10}$ argentophilic $\left(\mathrm{Ag}^{\mathrm{I}} \cdots \mathrm{Ag}^{\mathrm{I}}\right)$ or aurophilic $\left(\mathrm{Au}^{\mathrm{I}} \cdots \mathrm{Au}^{\mathrm{I}}\right)$ interactions which effectively increase the dimensionality (Pyykko, 1997; Liu et al., 2006). In addition, theoretical studies on dimeric models of linear two-coordinate complexes indicate that the strengths of such interactions are within the range of typical hydrogen bonds (Magnko et al., 2002), the latter being perhaps the most widely applied tool for the increase of dimensionality and control of supramolecular architecture.

Recently, various coordination polymers have been discovered which employ the $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$ligand as a building block. For examples, 1-D chain $\left[\mathrm{Cu}(4-\mathrm{Mepy})_{2}\right.$ $\left.\mathrm{Ag}_{2}(\mathrm{CN})_{4}\right]$ (Tričíková et al., 2003), $\left[\mathrm{Cu}(\mathrm{en})_{2}\right]\left[\mathrm{Ag}_{2}(\mathrm{CN})_{3}\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right],\left[\mathrm{Mn}(\mathrm{NITpPy})_{2}\right]$ $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]_{2}$ (Dasna et al., 2001), $\left[\mathrm{Ni}(\right.$ tren $\left.) \mathrm{Ag}(\mathrm{CN})_{2}\right]\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ (Shorrock et al., 2002), $\left[\mathrm{Cu}(\mathrm{en})_{2} \mathrm{Ag}_{2}(\mathrm{CN})_{4}\right]$ (Černák et al., 1998), $\left[\mathrm{Ni}(\mathrm{en})_{2} \operatorname{Ag}(\mathrm{CN})_{2}\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ (Ren et al., 2005), 2-D network $\left[\mathrm{Ni}(\mathrm{en})_{2} \mathrm{Ag}_{3}(\mathrm{CN})_{5}\right]$ (Zhang et al., 1999), 2-D interpenetrating nets $\left[\mathrm{Cu}(\mathrm{en}) \mathrm{Cu}(\mathrm{CN})_{2} \operatorname{Ag}(\mathrm{CN})_{2}\right]$ (Shorrock et al., 2002), $\left[\mathrm{Ni}(\mathrm{en})_{2}\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]_{2}\left[\mathrm{Ag}_{2}(\mathrm{CN})_{2}\right]$ (Duriska et al., 2006), 3-D networks $\left[\mathrm{Ag}_{4} \mathrm{Cd}_{2}(\operatorname{tren})_{2}(\mathrm{CN})_{6.5}\right]\left[\mathrm{Ag}(\mathrm{CN})_{1.5}\right]$ (Zhang et al., 2002), $\left[\mathrm{Cu}(\text { dien }) \mathrm{Ag}(\mathrm{CN})_{2}\right]_{2}\left[\mathrm{Ag}_{2}(\mathrm{CN})_{3}\right]\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ (Lescouëzec et al., 2003), and 3-D doubly interpenetrating $\left[\mathrm{Cd}(\mathrm{pyz}) \mathrm{Ag}_{2}(\mathrm{CN})_{3} \operatorname{Ag}(\mathrm{CN})_{2}\right]$ (Soma et al., 1994).

The present work forms part of a research program on the chemistry of cyanide-bridged bimetallic coordination polymers with the primary aim of synthesizing 1-D tube-like motifs using $\left[\mathrm{M}(\text { bidentate })(\mathrm{CN})_{4}\right]^{2-}$ donors and $\left[\mathrm{M}(\text { bidentate })(\text { solvent })_{4}\right]^{2+}$ acceptors as building blocks. A more general aim was to study the structural diversity and magnetic properties of cyanide-bridged and cyanometallate-bridged compounds. In this chapter, the initial aim was to use a linear dicyanoargentate $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$as bridging ligand to replace CN groups of the $\left[\mathrm{M}(\text { bidentate })(\mathrm{CN})_{4}\right]^{2-}$ building block (see Chapter III). The aromatic planar $2,2^{\prime}-$ bipyridine (2,2'-bipy) bidentate ligand is used here to block two coordination sites in the acceptor group. This approach is expected to produce 1-D tube-like motifs of $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ bridged bimetallic coordination polymers. But other stoichiometries and topologies are possible even when $\mathrm{M}^{\mathrm{II}}:\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$ratios of 1:1 are used. Thus, new supramolecular complexes can be formed that involve interactions such as argentophilic, hydrogen bonding, and $\pi \cdots \pi$ interactions. The synthesis and structures of four new mixed-metal compounds of $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (4a), $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \operatorname{Ag}(\mathrm{CN})_{2} \quad(\mathbf{4 b})$ and two coordination polymers $\left[\mathrm{Ag}_{4}(\mathrm{CN})_{7}\left\{\mathrm{Cd}\left(2,2^{\prime}-\text { bipy }\right)\right\}_{2}\right] \cdot\left[\mathrm{ClO}_{4}\right]$ (4c) and $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Cd}\left(2,2^{\prime}\right.\right.$-bipy $\left.)\right]$ (4d) are described. 4a and 4b display supramolecular structures, while $\mathbf{4 c}$ and $\mathbf{4 d}$ are coordination polymers. Their structures contain $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ units which behave as building blocks as well as increasing the dimensionality and stabilizing the crystal structures through interactions of the argentophilic $(\mathrm{Ag} \cdots \mathrm{Ag}), \mathrm{Ag} \cdots \mathrm{N}$ and $\mathrm{Ag} \cdots \pi$ types. The temperature dependent magnetic behavior of $\mathbf{4 b}$ is also examined.

### 4.2 Experimental Section

### 4.2.1 Materials and Physical Measurements

$\mathrm{KAg}(\mathrm{CN})_{2}, \mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Cd}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, and $2,2^{\prime}-$ bipy were commercially available, and were used without further purification.

Caution!: Perchlorate salts of metal complexes with organic ligands are potentially explosive. Only small amounts of material should be prepared, and these should be handled with care. Cyanide is very poisonous. Great care should be taken that its salts do not come into contact with acid, which liberates highly toxic hydrogen cyanide gas. It should not be touched with the fingers; use a spatula or handle small pieces with pincers, and reactions were performed under a fume hood.

Microanalytical measurements ( $\mathrm{C}, \mathrm{H}, \mathrm{N}$ ) were performed by Campbell Microanalytical Laboratory, Chemistry Department, University of Otago, Dunedin, New Zealand. Infrared spectra of Nujol mulls were recorded using a diamond-ATR cell on a Bruker Opus/IR IFS 55 spectrometer in the range of $600-4000 \mathrm{~cm}^{-1}$ (50 scans, resolution $\pm 4 \mathrm{~cm}^{-1}$ ). Variable-temperature magnetic susceptibility data were obtained by Dr. Boujemaa Moubaraki, Department of Chemistry, Monash University, using a Quantum Design MPMS 5 SQUID magnetometer for DC magnetization measurements.

### 4.2.2 Syntheses

Preparation of $\left[\left\{\mathbf{A g}(\mathbf{C N})_{2}\right\}_{2} \mathbf{M n}\left(\mathbf{2}, \mathbf{2}^{\prime} \text {-bipy }\right)_{2}\right] \cdot \mathbf{H}_{\mathbf{2}} \mathrm{O}$ (4a)
A crystalline sample of $\mathbf{4 a}$ was obtained using the slow diffusion method in which an aqueous solution of 14 mL capacity was contained in an H -shaped tube and left in the dark. In a typical experiment, $\operatorname{KAg}(\mathrm{CN})_{2}(40 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved in 3 mL of distilled water to form a bright colorless solution, and this was pipetted
into one side of the H-tube. $\mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(57 \mathrm{mg}, 0.2 \mathrm{mmol})$ and $2,2^{\prime}$-bipy ( 31 mg , 0.2 mmol ) were dissolved in 3 mL of distilled water to give a bright yellow aqueous solution, and this was pipetted into the other side arm of the H -tube. The H-tube was then carefully filled with distilled water. Upon slow diffusion for two weeks, paleyellow shaped single crystals of $\mathbf{4 a}$ were formed in the silver-containing side of the H-tube. Yield: 25 mg ( $63 \%$ based on $\operatorname{KAg}(\mathrm{CN})_{2}$ ). Anal. Found (calcd) for $\mathrm{C}_{24} \mathrm{H}_{20} \mathrm{Ag}_{2} \mathrm{MnN}_{8} \mathrm{O}(\mathrm{Mr}=705.14 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 40.85(40.88) ; \mathrm{H}, 2.80(2.79), \mathrm{N}, 15.92$ (15.89). ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 648 \mathrm{~m}, 737 \mathrm{~s}, 765 \mathrm{~s}, 1013 \mathrm{~s}, 1154 \mathrm{~m}, 1312 \mathrm{~m}, 1436 \mathrm{~s}$, $1471 \mathrm{~s}, 1489 \mathrm{~s}, 1575 \mathrm{~s}, 1594 \mathrm{~m}, 1630 \mathrm{w}, 2134 \mathrm{~s}, 2155 \mathrm{~s}, 3050 \mathrm{w}, 3089 \mathrm{w}, 3120 \mathrm{w}, 3468 \mathrm{~m}$, 3534br.

## Preparation of $\left[\mathrm{Ag}(\mathbf{C N})_{\mathbf{2}} \mathbf{M n}\left(\mathbf{2 , 2} \mathbf{2}^{\prime}-\text { bipy }\right)_{\mathbf{2}}\left(\mathrm{H}_{\mathbf{2}} \mathrm{O}\right)\right]\left[\mathrm{Ag}(\mathrm{CN})_{\mathbf{2}}\right](4 \mathrm{~b})$

The compound $\mathbf{4 b}$ was prepared by a similar procedure to that described for 4a above, in methanol/water (1:1, v/v) solution with $\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ being used instead of $\mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$. X-ray quality pale-yellow block shaped single crystals of 4b were formed in the silver-containing side after two weeks. Yield: $28 \mathrm{mg}(70 \%)$. Anal. Found (calcd) for $\mathrm{C}_{24} \mathrm{H}_{18} \mathrm{Ag}_{2} \mathrm{MnN}_{8} \mathrm{O}(M r=705.14 \mathrm{~g} / \mathrm{mol}) \mathrm{C}, 40.86(40.88)$; H , $2.57(2.79), \mathrm{N}, 15.87(15.89)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 733 \mathrm{~s}, 759 \mathrm{~s}, 1013 \mathrm{~s} 1437 \mathrm{~s}, 1472 \mathrm{~s}$, $1566 \mathrm{~m}, 1575 \mathrm{~m}, 1595 \mathrm{~s}, 2142 \mathrm{w}, 2153 \mathrm{~s}, 2611 \mathrm{br} 2649 \mathrm{br}, 2664 \mathrm{br}, 2744 \mathrm{br}, 3097 \mathrm{br}$, 3596 br , 3619br, 3644br, 3679br, 3764br.

## Preparation of $\left[\mathrm{Ag}_{4}(\mathbf{C N})_{7}\left\{\mathbf{C d}\left(\mathbf{2 , 2} \mathbf{2}^{\prime} \text {-bipy }\right)\right\}_{2}\right] \mathrm{ClO}_{4}(4 \mathrm{c})$ and $\left[\left\{\operatorname{Ag}(\mathbf{C N})_{2}\right\}_{2} \mathbf{C d}\left(\mathbf{2}, \mathbf{2}^{\prime}-\right.\right.$-bipy $\left.)\right](4 d)$

The samples were prepared by a similar procedure to that described above for 4b, in methanol/water $(1: 1, \mathrm{v} / \mathrm{v})$ solution, and $\mathrm{Cd}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ was used instead of
$\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$. X-ray quality colorless plate- (4c) and block- (4d) shaped single crystals were formed after two weeks.

Major phase 4c: yield, $18.4 \mathrm{mg}\left(46 \%\right.$ based on $\left.\operatorname{KAg}(\mathrm{CN})_{2}\right)$. Anal. Found (calcd) for $\mathrm{C}_{37} \mathrm{H}_{32} \mathrm{Ag}_{4} \mathrm{Cd}_{2} \mathrm{ClN}_{15} \mathrm{O}_{4}(M r=1562.63 \mathrm{~g} / \mathrm{mol})$ : C, $37.01(36.13)$; $\mathrm{H}, 2.19$ (2.06), $\mathrm{N}, 13.52(13.45)$. ATR-FTIR ( $v_{\max } / \mathrm{cm}^{-1}$ ): 736m, 762s, 1018m, 1154m, 1314m, 1438s, 1473s, 1489m, 1567m, 1577w, 1593w, 1601s, 2129w, 2139w, 2159s, 3053w, 3088w, 3112w, 3464w, 3535w.

Minor phase 4d: yield, $2 \mathrm{mg}\left(5 \%\right.$ based on $\left.\operatorname{KAg}(\mathrm{CN})_{2}\right)$. ATR-FTIR ( $v_{\max }$ ) $\left.\mathrm{cm}^{-1}\right): 737 \mathrm{~m}, 767 \mathrm{~s}, 1314 \mathrm{~m}, 1439 \mathrm{~s}, 1473 \mathrm{~s}, 1576 \mathrm{~m}, ~ 1599 \mathrm{~s}, 2130 \mathrm{~s}, 2137 \mathrm{~m}, 2155 \mathrm{~s}$, 2163m, 3051w, 3083w, 3109w, 3192w, 3471br, 3538br, 3847w.

### 4.2.3 X-Ray Crystallographic Study

Single crystals of $\mathbf{4 a}-\mathbf{4 d}$ were mounted on a MiTeGen MicroMounts fiber in a small amount of oil and prior to measurements made by Dr. Suzanne M. Neville and Dr. Craig Forsyth, Monash University. Reflection intensities were collected on a Bruker X8 APEX CCD diffractometer (Mo $K_{\alpha}$ radiation, $\bar{\lambda}=0.71073$ Å) and equipped with an Oxford Instruments nitrogen gas Cryostream. Empirical absorption corrections were applied to all data using SADABS (Blessing, 1995). The structures were solved using SHELXS-97 (Sheldrick, 1997) and refined on $F^{2}$ using SHELXL97 (Sheldrick, 1997) with X-SEED (Barbour, 2001) as a graphics interface.

In the final cycles of refinement, all atoms except hydrogen atoms and disorder molecules were refined anisotropically. Hydrogen atoms attached to carbon atoms of $2,2^{\prime}$-bipy molecules were placed in idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}$ distance at $0.95 \AA$, with $U_{\mathrm{iso}}(\mathrm{H})=1.2 U_{\mathrm{eq}}(\mathrm{C})$.

For $\mathbf{4 a}$ and $\mathbf{4 b}$, hydrogen atoms attached to oxygen atoms of the water molecules were located in a difference Fourier map and refined as riding in their asfound positions with a DFIX restraint of $\mathrm{O}-\mathrm{H}$ distance at $0.90 \AA$, with $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\mathrm{eq}}(\mathrm{O})$.

For $\mathbf{4 c}$, the cyanide group, $\mathrm{C} 4 \equiv \mathrm{~N} 4$, was modeled as disordered over the symmetry site, with both atoms occupying the same site in the asymmetric unit and treated as a hybrid atom of $50 \% \mathrm{~N}$ and $50 \% \mathrm{C}$ in the structure refinement. The $\mathrm{ClO}_{4}$ anions were also disordered over inversion centers, and were refined with restrained $\mathrm{Cl}-\mathrm{O}$ distances and the $U_{\text {iso }}$ for the O atoms constrained to be the same.

Crystal data and details of the data collection, and structure refinement for $\mathbf{4 a}-$ 4d are summarized in Table 4.1. Selected interatomic bond lengths and angles for $\mathbf{4 a} \mathbf{-}$ 4d are given in Tables 4.2-4.4. Intra- and intermolecular hydrogen bonds and geometrical parameters of $\pi-\pi$ interactions for all compounds are provided in Tables 4.5 and 4.6 , respectively. Other crystallographic data are given as supplementary material in a CIF in the attached CD-ROM.

Table 4.1 Summary of crystallographic data for the compounds $\mathbf{4 a}-\mathbf{4 d}$.

### 4.3 Results and Discussion

### 4.3.1 Synthesis and ATR-IR Spectra

Reaction of $\mathrm{Mn}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{K}\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$, and $2,2^{\prime}$-bipy in a 1:1:1 molar ratio in an aqueous or methanol/water solutions afforded pale-yellow block-shaped single crystals of the new complexes $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (4a) and $\left[\operatorname{Ag}(\mathrm{CN})_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \operatorname{Ag}(\mathrm{CN})_{2}$ (4b) in good yields. The crystallizing solvent and the counter anions have profound effects on the structures of the products. Both compound have $\operatorname{Ag}(\mathrm{CN})_{2}: \mathrm{Mn}: 2,2^{\prime}$-bipy ratios of 2:1:2, thus a mole equivalent of $\mathrm{Mn}(\mathrm{II})$ remains in solution. A methanol/water solution of $\mathrm{Cd}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ containing one equivalent of $2,2^{\prime}$-bipy with a methanol/water solution of one equivalent of $\mathrm{K}\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ afforded a major product of colorless plate shaped crystals of $\left[\mathrm{Ag}_{4}(\mathrm{CN})_{7}\left\{\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right\}_{2}\right] \mathrm{ClO}_{4}(\mathbf{4 c})$ and traces of block-shaped crystals of $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathrm{Cd}\left(2,2^{\prime}\right.\right.$-bipy $\left.)\right]$ (4d). Interestingly, compound $\mathbf{4 c}$ has $\operatorname{Ag}(\mathrm{CN})_{2}: \mathrm{Cd}: 2,2^{\prime}$-bipy ratios of 2:1:2, while 4 d has $2: 1: 1$. Attempts to grow crystals using $\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{2} \cdot x \mathrm{H}_{2} \mathrm{O}, \mathrm{Co}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{Zn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ instead of $\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{Cd}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ using the same procedure as in $\mathbf{4 b}$ were unsuccessful. Despite many attempts, the crystals obtained were always very small, often twinned and of poor quality.

Bridging or terminal cyano groups can usually be differentiated by the positions of the corresponding infrared $v(\mathrm{CN})$ stretching absorption bands. Typically, bridging CN ligands have higher stretching frequencies than the terminal CN ligand (Nakamoto, 1963). The solid state IR spectrum of $\mathrm{K}\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ had $v(\mathrm{CN})$ band at $2134 \mathrm{~cm}^{-1}$. The CN stretching region of the solid state IR spectrum of $\mathbf{4 a}$ and $\mathbf{4 b}$ is consistent with the presence of bridging cyano groups with $v(\mathrm{CN})$ at 2155 s and 2153 s
$\mathrm{cm}^{-1}$, and terminal cyano groups at 2134 s and $2142 \mathrm{w} \mathrm{cm}^{-1}$, respectively. The infrared spectrum of $\mathbf{4 c}$ had a $v(\mathrm{CN})$ band at $2159 \mathrm{~s} \mathrm{~cm}^{-1} .4 \mathbf{d}$ has $v(\mathrm{CN})$ bands at 2154 s and $2163 \mathrm{~s} \mathrm{~cm}^{-1}$, at higher wavenumbers than that of free $\mathrm{K}\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$, indicating all the cyano groups are bridging. These results are consistent with the single crystal X-ray studies.

### 4.3.2 Structural Description of $\left[\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{2} \mathbf{M n}\left(2,2^{\prime} \text {-bipy }\right)_{2}\right] \cdot \mathbf{H}_{2} \mathrm{O}$ (4a)

4a crystallizes in a monoclinic system with the space group $P 2_{1} / n$ (No. 14). The asymmetric unit consists of one $\left[\mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\right]^{2+}$ fragment and two distinct $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$units in general positions, and half of two water molecules of crystallization on a special positions, in Figure 4.1. The structure consists of discrete metal complexes and intercalated water molecules.

The Mn (II) center is cis six-coordinated by four $2,2^{\prime}$-bipy nitrogen and two cyanide nitrogen atoms to form a distorted octahedral geometry. The $\mathrm{Mn}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths range from $2.240(3)$ to $2.279(3) \AA$, and are comparable to those observed in other 2,2'-bipy containing manganese(II) complexes; cis-[Mn(2,2'bipy $\left.)_{2}(\mathrm{NCS})_{2}\right]$ (Veidis et al., 1981) and cis-[Mn(2,2'-bipy $\left.)_{2}(\mathrm{Cl})_{2}\right]$ (Lumme and Lindell, 1988). The $\mathrm{Mn}-\mathrm{N}_{\mathrm{CN}}$ bond lengths at 2.177(4) and 2.186(4) $\AA$ are slightly shorter than the $\mathrm{Mn}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths. Similar shorter bonds for $\mathrm{Mn}-\mathrm{N}_{\mathrm{CN}}$ versus $\mathbf{M n}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ in $\mathbf{4 a}$ are observed in $c i s-\left[\mathrm{Mn}\left(2,2^{\prime} \text {-bipy }\right)_{2}(\mathrm{NCS})_{2}\right]$ (Veidis et al., 1981), cis-[Mn(1,10-phen $\left.)_{2}(\mathrm{NCS})_{2}\right]$ (Hollenman et al., 1994), and cis-[Mn(1,10-phen $)_{2}$ $(\mathrm{dca})_{2}$ ] (Wang et al., 2000). The $\mathrm{Mn}-\mathrm{N}-\mathrm{C}$ bond angles are 162.6(4) and 163.0(4) ${ }^{\circ}$.

The two $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$units in $\mathbf{4 a}$ is somewhat bent. The $\mathrm{C}-\mathrm{Ag}-\mathrm{C}$ bond angles range from $165.6(1)$ to $166.6(1)^{\circ}$, and the $\mathrm{Ag}-\mathrm{C}-\mathrm{N}$ bond angles are in the 173.2(4) and $176.4(4)^{\circ}$ range. The $\mathrm{Ag}-\mathrm{C}$ bond lengths range from 2.048(5) to 2.068(5) $\AA$.

These values are slightly different to that reported for the free $\operatorname{Ag}(\mathrm{CN})_{2}$ molecules (Victoria et al., 2005) caused by the cyanide group from $\operatorname{Ag}(\mathrm{CN})_{2}$ bridging to the manganese (II) centre.

Figure 4.1 Perspective view of $\mathbf{4 a}$ with the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are shown as small spheres of arbitrary radii. The labeling scheme, $A-D$, applied to the phenyl rings are used to identify the rings in subsequent discussion.

The $2,2^{\prime}$-bipy ligands in $\mathbf{4 a}$ are essentially planar. A maximum deviation of $-0.082(3) \AA$ is observed at atom N8 from the least-squares plane of ring $D$. The bond lengths and angles within the $2,2^{\prime}$-bipy ring (1.333(5) to $1.482(6) \AA$ and $115.4(4)$ to $\left.124.0(5)^{\circ}\right)$ are all normal and compare well with those observed for the free $2,2^{\prime}$-bipy molecules (Merritt and Schroeder, 1956). The dihedral angle between the leastsquares planes through the two $2,2^{\prime}$-bipy ligands containing rings $\mathrm{A} / \mathrm{B}$ and rings $\mathrm{C} / \mathrm{D}$ is $78.7(1)^{\circ}$. The bite angle of $2,2^{\prime}$-bipy is $72.2(1)$ and $72.8(1)^{\circ}$ for $\mathrm{N} 5-\mathrm{Mn} 1-\mathrm{N} 6$ and

N7-Mn1-N8, respectively. This is one of the main factors accounting for this distortion from ideal octahedral geometry (angle of $90^{\circ}$ ) of the $\mathrm{Mn}(\mathrm{II})$ centre.

Figure 4.2 Packing diagram of 4a view along the $c$ axis. Included water molecules are represented as space-filling model.

The crystal packing view along the crystallographic $c$ axis in $\mathbf{4 a}$ is shown in Figure 4.2. A number of supramolecular interactions are observed within the solid state packing. The unligated N -end (nitrile) of the monodentate $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ anions, N 4 , is bonded at $2.753(4) \AA$ to the Ag 1 atoms of adjacent component into chains running parallel to the $a$ direction, Figure 4.3a. The value of this $\mathrm{Ag} \cdots \mathrm{N}$ contact in $\mathbf{4 a}$ is well below the sum of the van der Waals radii $[1.72(\mathrm{Ag})+1.54(\mathrm{~N})=3.26 \AA]$ (Bondi, 1964) and within the range of other $\mathrm{Ag} \cdots \mathrm{N}$ inteactions (2.7-3.1 $\AA$ ) reported in the literature (Withersby et al., 1997; Batten et al., 1998; Janiak et al., 1999). The

Figure 4.3 Views of supramolecular interactions in $\mathbf{4 a}$ (a) $\mathrm{Ag} \cdots \mathrm{N}$, (b) $\pi \cdots \pi$ and (c) P4AE C $-\mathrm{H} \cdots \pi$ interactions.
chains are then interconnected through offset head-to-head $\pi-\pi$ interactions (off) between the pyridyl groups of the $2,2^{\prime}$-bipy ligands as shown in Figure 4.3b. The closest distances of approach between the pyridyl rings are 3.402(7) and 3.571(6) $\AA$ for ring $A \cdots$ ring $C$ and ring $B \cdots$ ring $D$, respectively. Ring $C$ reinforces the supramolecular structure of $\mathbf{4 a}$ by additional $\mathrm{C}-\mathrm{H} \cdots \pi$ edge-to-face type interactions from hydrogen atoms, H12, of the stacked aryl rings, pointing towards the faces of aryl rings $C$ at a distance of $2.508(7) \AA$. This result in centrosymmetric, achiral, parallel fourfold aryl embraces (P4AE), containing one off interaction, and two ef interactions (Dance and Scudder, 1996) as illustrated Figure 4.3c. These interactions are associated to give the resulting 2-D square grid, and are further linked together between grids to form 3-D supramolecular architectures along the crystallographic $c$ axis as shown in Figure 4.4.

Figure 4.4 Crystal packing in $\mathbf{4 a}$ along the $c$ axis showing a single (space-filling) and second (ball and stick) square grids formed via $\mathrm{Ag} \cdots \mathrm{N}, \mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ interactions.

In order to investigation the argentophilic $(\mathrm{Ag} \cdots \mathrm{Ag})$ interactions, a CSD (version 5.29 updates January 2008) search was carried out with the help of the ConQuest (version 1.10) program (Allen et al., 1991). The result for a search on complexes having $\mathrm{Ag} \cdots \mathrm{Ag}$ interactions between two $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ fragments with the $\mathrm{Ag} \cdots \mathrm{Ag}$ contact constrained to be less than the sum of van der Waals radii of two Ag atoms, $3.44 \AA$ (Bondi, 1964), is illustrated in Figure 4.5. A typical range for these $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts is $c a .2 .95$ to $3.30 \AA$. The interchain $\mathrm{Ag} \cdots \mathrm{Ag}$ separation in $\mathbf{4 a}$ is $3.847(1) \AA$, which is greatly longer than the sum of its van der Waals radii. Thus, this value is considered to be a very weak van der Waals contact.

Figure 4.5 Histogram plot of distribution of $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts between two $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ fragments obtained from the CSD (version 5.29 updates January 2008).

Furthermore, the uncoordinated water molecules of O 1 and O 2 act as both hydrogen bond donors and acceptors participating in two strong ( $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}=2.982(5)$ and 3.031(6) $\AA$ ) and two weak $(\mathrm{C}-\mathrm{H} \cdots \mathrm{O}=3.383(7)$ and 3.451(7) $\AA$ ) hydrogen bonds, thereby producing an infinite chain running parallel to the $c$ direction, as shown in Figure 4.6.

Figure 4.6 Part of the crystal structure of $\mathbf{4 a}$, showing the formation of an infinite $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ chain running parallel to the $c$ direction.

### 4.3.3 Structural Description of $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathbf{M n}\left(2,2^{\prime}-\mathrm{bipy}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathbf{A g}(\mathrm{CN})_{2}(\mathbf{4 b})$

Unlike compound $\mathbf{4 a}$, the single crystal X-ray diffraction analyses of $\mathbf{4 b}$ revealed that a water molecule is coordinated to the $\mathrm{Mn}(\mathrm{II})$ centre, and there is also one isolated $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]$ anion. 4a crystallizes in the monoclinic space group $P 2_{1} / c$ (No. 14). The asymmetric unit contains one $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathrm{Mn}\left(2,2^{\prime}-\text { bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{+}$cation and one uncoordinated $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$anions in general positions, Figure 4.7.

Figure 4.7 Perspective view of $\mathbf{4 b}$ with the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity. The labeling scheme, $E-G$, applied to the phenyl rings are used to identify the rings in subsequent discussion.

Again, the $\mathrm{Mn}(\mathrm{II})$ centre is cis six-coordinated by four $2,2^{\prime}$-bipy nitrogen, one cyanide nitrogen, and one water oxygen atoms, taking a distorted octahedral geometry. The dihedral angle of the $2,2^{\prime}$-bipy planes of $78.3(1)^{\circ}$ in $\mathbf{4 b}$ is essentially the same as that found in $\mathbf{4 a}$. The $\mathrm{Mn}-\mathrm{N}_{\mathrm{CN}}\left(2.196(2) \AA\right.$ ) and the $\mathrm{Mn}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths (2.240(3) to $2.273(3) \AA$ ) are comparable to that found in $\mathbf{4 a}$.

The two $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$groups in $\mathbf{4 b}$ are almost linear with the $\mathrm{C}-\mathrm{Ag}-\mathrm{C}$ bond angles ranging from $172.5(1)$ to $175.9(1)^{\circ}$ and the $\mathrm{Ag}-\mathrm{C}-\mathrm{N}$ bond angles in the $171.9(2)$ to $176.7(3)^{\circ}$ range. The bond lengths and angles involving the $2,2^{\prime}$-bipy molecules are comparable to those of $\mathbf{4 a}$. The bite angles of $2,2^{\prime}$-bipy molecules are respectively at $71.8(1)$ and $72.9(1)^{\circ}$ for $\mathrm{N} 5-\mathrm{Mn} 1-\mathrm{N} 6$ and for $\mathrm{N} 7-\mathrm{Mn} 1-\mathrm{N} 8$, which is one of the main factors accounting for the distortion of manganese(II) centre.

A significant difference between the structures of $\mathbf{4 a}$ and $\mathbf{4 b}$ is the presence the argentophilic $(\mathrm{Ag} \cdots \mathrm{Ag})$ interactions and the absence of $\mathrm{Ag} \cdots \mathrm{N}$ interactions and weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds in $\mathbf{4 b}$. As shown in Figure 4.8 a, the $\left[\mathrm{Mn}\left(2,2^{\prime}-\right.\right.$ bipy $\left.)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right) \operatorname{Ag}(\mathrm{CN})_{2}\right]^{+}$cation and $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$anion portions make contact to each other via argentophilic interactions and generate a 1-D zigzag chain parallel to the crystallographic $c$ axis. The $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts are $3.188(1)$ and $3.775(1) \AA$ for $\mathrm{Ag} 1-\mathrm{Ag} 2$ and $\mathrm{Ag} 1^{\mathrm{i}}-\mathrm{Ag} 2$ (symmetry code: $(\mathrm{i})=x, 1.5-y, z-0.5$ ), respectively. The dihedral angles between two $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$fragments are $84.0(1)[\mathrm{N} 1-\mathrm{C} 1-\mathrm{Ag} 1-\mathrm{C} 2$ -N 2 and $\mathrm{N} 3-\mathrm{C} 3-\mathrm{Ag} 2-\mathrm{C} 4-\mathrm{N} 4]$ and $83.5(1)^{\circ}\left[\mathrm{N} 1^{\mathrm{i}}-\mathrm{C} 1^{\mathrm{i}}-\mathrm{Ag} 1^{\mathrm{i}}-\mathrm{C} 2^{\mathrm{i}}-\mathrm{N} 2^{\mathrm{i}}\right.$ and $\mathrm{N} 3-\mathrm{C} 3$ $-\mathrm{Ag} 2-\mathrm{C} 4-\mathrm{N} 4$, symmetry code: $(\mathrm{i})=x, 1.5-y, z-0.5]$. For these $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts, one is significantly shorter and one longer than the sum of the van der Waals radii of two $\mathrm{Ag}(\mathrm{I})$ centers, $3.44 \AA$ (Bondi, 1964). Therefore, the former and latter interactions indicate the presence of strong argentophilic and weak van der Waals interactions, respectively. There is an additional hydrogen bonding interaction between O 1 and N 2 at $2.745(4) \AA$ which helps to stabilize the chain. Each chain in $\mathbf{4 b}$ is linked through weak $\pi \cdots \pi$ stacking interactions with the shortest $\mathrm{C} \cdots \mathrm{C}$ distance between the pyridine rings of adjacent chains being $3.231(4) \AA$, thus creating a 2-D array parallel to the crystallographic $c$ axis as shown in Figure 4.8b.

There are additional $\mathrm{O} \cdots \mathrm{N}$ hydrogen bonding $(\mathrm{O} 1 \cdots \mathrm{~N} 4=2.745(4) \AA)$ and $\pi-\pi$ stacking interactions of the pyridine rings between the 2-D arrays which hold the components together into a 3-D supramolecular structure as well as make the crystal structure more stable (Tables 4.5 and 4.6).

(a)

(b)

Figure 4.8 The 2-D sheet in $\mathbf{4 b}$ via intermolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds, $\mathrm{Ag} \cdots \mathrm{Ag}$, and $\pi \cdots \pi$ interactions.

### 4.3.4 Structural Description of $\left[\mathrm{Ag}_{4}(\mathbf{C N})_{7}\left\{\mathbf{C d}\left(2,2^{\prime} \text {-bipy }\right)\right\}_{2}\right] \mathrm{ClO}_{4}(\mathbf{4 c})$

4c crystallizes in the monoclinic space group $C 2 / c$ (No. 15). The structure consists of 1-D polymer ladders of $\left[\mathrm{Ag}_{4}(\mathrm{CN})_{7}\left\{\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right\}_{2}\right]$ cations, charge balanced by disordered $\left[\mathrm{ClO}_{4}\right]$ counter anions, Figure 4.9. Similar to the coordination environment of the $\mathrm{Mn}(\mathrm{II})$ ion in $\mathbf{4 a}$, the $\mathrm{Cd}(\mathrm{II})$ centre in $\mathbf{4 c}$ is cis six-coordinated by four $2,2^{\prime}$-bipy nitrogen and two cyanide nitrogen atoms, and adopts a distorted octahedral coordination geometry. The $\mathrm{Cd}^{-}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths (2.240(3) and $2.279(3) \AA$ ) are somewhat shorter than the $\mathrm{Cd}-\mathrm{N}_{\mathrm{CN}}$ bonds lengths (2.265(3) and $2.295(3) \AA$ ). The dihedral angle between the least-squares planes through the two $2,2^{\prime}$-bipy ligands containing rings $I / J$ and $K / L$ is $72.5(1)^{\circ}$.

Figure 4.9 Perspective view of $\mathbf{4 c}$ with the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarify. The labeling scheme, $I-L$, applied to the phenyl rings are used to identify the rings in the subsequent discussion.

Two different environments can be distinguished for the $\operatorname{Ag}(\mathrm{I})$ atoms. $\operatorname{Ag} 1$ is coordinated to the $\mathrm{Cd}(\mathrm{II})$ centre through the N 1 cyanide, and to Ag 2 via the N 2 cyanide, while Ag 2 is similarly bonded to the $\mathrm{Cd}(\mathrm{II})$ centre through the N 3 atom and to another Ag2 via the $\mathrm{C} 4 / \mathrm{N} 4$ atom in which crystallographic occupancy of $\mathrm{C} / \mathrm{N}$ atoms in cyanide was 0.5 for each. The $\left[\mathrm{Ag} 1(\mathrm{CN})_{2}\right]^{-}$and $\left[\mathrm{Ag} 2(\mathrm{CN})_{2}\right]^{-}$groups in $\mathbf{4 c}$ do not have similar geometrical characteristics. Site Ag 1 is almost linear, while the Ag 2 site is more bent. The $\mathrm{C}-\mathrm{Ag}-\mathrm{C}$ bond angles are $174.8(1)$ and $157.3(1)^{\circ}$ for $\mathrm{C} 1-\mathrm{Ag} 1-\mathrm{C} 2$ and $\mathrm{C} 3-\mathrm{Ag} 2-\mathrm{C} 4 / \mathrm{N} 4$, respectively. The $\mathrm{Ag}-\mathrm{C}-\mathrm{N}$ bond angles are in the range $170.0(3)$ to $176.6(3)^{\circ}$. The $\mathrm{Ag}-\mathrm{C}$ bond lengths range from 2.046(3) to 2.073(3) $\AA$ which is similar to those found in $\mathbf{4 a}$ and $\mathbf{4 b}$.

Figure 4.10 View of 1-D ladder like chain in $\mathbf{4 c}$.

Figure 4.11 (a) Ball and stick and (b) space-filling representation showing two ladder chains in $\mathbf{4 c}$ viewed along the $b$ axis.

As shown in Figures 4.10 and 4.11, cationic ladders are generated. The sides of the ladders are built by $\left[\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right]^{2+}$ moieties being bridged by $\left[\mathrm{Ag}_{2}(\mathrm{CN})_{3}\right]^{-}$ groups. The rungs are created by the disordered C4/N4 cyanide bridging between Ag 2 atoms. The dimension of the 24 -memberred square cavities is $10.632(3) \times$ $11.051(3) \AA$. Each square is occupied by a $\left[\operatorname{Cd}\left(2,2^{\prime} \text {-bipy }\right)_{2}\right]^{2+}$ fragment from a neighboring ladder chain and a $\left[\mathrm{ClO}_{4}\right]^{-}$counter anion. There is no intermolecular $\mathrm{Ag} \cdots \mathrm{Ag}$ contact less than $3.44 \AA$ (Bondi, 1964). The shortest intermolecular $\mathrm{Ag} \cdots \mathrm{Ag}$ distance of $4.043(1) \AA$ is too long to be regarded as a significant argentophilic interaction. There are, however, weak interactions of $\operatorname{Ag} 1 \cdots \pi($ ring $J)$ at $3.374(1) \AA$ between the ladders.

The adjacent ladder chains are further aggregated into 2-D sheets through the offset head-to-head $\pi-\pi$ interactions with the closest distance of approach between the pyridyl rings of $2,2^{\prime}$-bipy molecules of adjacent chains being $3.361(4) \AA$, as shown in Figure 4.12.

It is also worthwhile to note that the 2-D sheets form a 3-D supramolecular structure via an intermolecular edge-to-face $\mathrm{C}-\mathrm{H} \cdots \pi$ interaction. The H 13 atoms point toward the faces of aryl rings $I$ at a distance of 2.608(3) $\AA$. A view of the crystal packing along the $b$ axis is presented in Figure 4.13. The included $\left[\mathrm{ClO}_{4}\right]^{-}$counter anions are located between the cationic chains, and interact with the $2,2^{\prime}$-bipy of the cationic chains, forming $\mathrm{C} \cdots \mathrm{O}$ hydrogen bonds with the distances ranging from $3.179(14)$ to $3.297(10) \AA$ (Table 4.5). These weak hydrogen bonds no doubt help to stabilize the supramolecular 3-D framework of $\mathbf{4 c}$.

Figure 4.12 The 2-D sheet in 4 c via intermolecular $\pi \cdots \pi$ interactions.

Figure 4.13 Crystal packing in $\mathbf{4 c}$ along the $a$ axis. Included perchlorate counter anions represented as space-filling model.

### 4.3.5 Structural Description of $\left[\left\{\operatorname{Ag}(\mathbf{C N})_{2}\right\}_{2} \mathbf{C d}\left(\mathbf{2}, \mathbf{2}^{\prime}-\right.\right.$-bipy $\left.)\right](4 d)$

$\mathbf{4 d}$ was separated from the same reaction as $\mathbf{4 c}$. Single crystal X-ray analysis reveals that $\mathbf{4 d}$ is composed of an interpenetrated polymeric structure without the present of any solvent molecules. $4 \mathbf{d}$ crystallizes in the monoclinic space group $P 2_{1} / c$ (No. 14). The asymmetric unit contains two independent $\mathrm{Cd}(\mathrm{II})$ and four distinct $\mathrm{Ag}(\mathrm{I})$ centers, all of which each lie on general positions, Figure 4.14.

Figure 4.14 Perspective view of $\mathbf{4 d}$ with the atom-numbering scheme. Displacement ellipsoids are drawn at the $50 \%$ probability level. Hydrogen atoms are omitted for clarity. The labeling scheme, $M-P$, applied to the phenyl rings are used to identify the rings in subsequent discussion. Symmetry codes: (i) $2-x,-1 / 2-y,-1 / 2-z$; (ii) $1+x,-1 / 2-y, 1 / 2+z$; (iii) $1-x,-1 / 2+y$, $1 / 2-z$.

The $\mathrm{Cd}($ II $)$ center has a slightly distorted $\left\{\mathrm{CdN}_{6}\right\}$ octahedral coordination sphere with two $2,2^{\prime}$-bipy nitrogen and four cyanide nitrogen atoms. The $\mathrm{Cd}-\mathrm{N}_{2,2^{\prime} \text {-bipy }}$ bond lengths in $\mathbf{4 d}$ range from $2.350(3)$ to $2.372(2) \AA$, and are slightly longer than the $\mathrm{Cd}-\mathrm{N}_{\mathrm{CN}}$ bond lengths, 2.257(2) and 2.387(2) $\AA$. The four $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]$ groups in $\mathbf{4 d}$ are very similar, and are somewhat bent. The $\mathrm{C}-\mathrm{Ag}-\mathrm{C}$ bond angles are in the 166.4(1) to $172.8(1)^{\circ}$ range, while the $\mathrm{Ag}-\mathrm{C}-\mathrm{N}$ bond angle range from 171.9(2) to $176.7(3)^{\circ}$. The $\mathrm{Ag}-\mathrm{C}$ bond lengths vary in the range 2.050 (3) to $2.064(3) \AA$, and are essentially the same as those found in $\mathbf{4 c}$. It should be noted that the $2,2^{\prime}$-bipy ligand coordinated to Mn2 centre is not planar. R. m. s. deviation of fitted atoms from the best plane calculated using twelve atoms (rings $M / N$ ) is $0.20 \AA$ with the largest deviation being $0.297(2) \AA$ at C12. The dihedral angle between the two planes is $23.6(1)^{\circ}$.

Figure 4.15 The 2-D sheet with the $(6,3)$ topology in $\mathbf{4 c}$.

The $\mathrm{Cd}(\mathrm{II})$ ions are linked by the four different types of $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$ligands into a 3-D network. The net may be described in terms of 2-D sheets in which the $\left[\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right]^{2+}$ moieties are bridged by the $\mathrm{Ag} 1, \mathrm{Ag} 2$ and Ag 4 containing anions. These sheets have a brickwork like $(6,3)$ topology, Figure 4.15 , with the rectangular widows having the dimensions $10.526(2) \times 21.650(2) \AA$. Each sheet is then bridged by the Ag3 anions to both the sheet above and the sheet below, to give an overall 3-D net, Figure 4.16. The Ag 3 anions bridge the two types of $\left[\mathrm{Cd}\left(2,2^{\prime} \text {-bipy }\right)\right]^{2+}$ groups, and create square windows. An overall 4-connected net is created, with both types of $\mathrm{Cd}(\mathrm{II})$ atoms acting as 4 -connecting nodes. Both nodes are topologically equivalent, and thus the net has the Schläfli symbol $4^{2} .6^{3} .8$ (Batten and Robson, 1998).

Figure 4.16 Schematic view of the 3-D 4-connected network with $4^{2} .6^{3} .8$ topology for 4d.

The 3-D net resulting the construction of two types of 1-D open channels along the crystallographic $b$ axis, as shown in Figures 4.16 and 4.17. The edge length of the 1 -D channel is $c a .10 .8 \AA$ but no guest molecules are encapsulated in the channels. Instead, the channels of a single 3-D net provide enough space for two other identical nets to interpenetrate, yielding three interpenetrating 3-D nets (4connected), as shown in Figure 4.18.

Figure 4.17 (a) Wires/sticks and (b) space filling representations of single 3-D framework with 1-D channels in $\mathbf{4 d}$ viewed along the $b$ axis.

An additional factor that also appears to influence the packing of the structure is weak $\mathrm{C}-\mathrm{H}^{\cdots} \pi$ hydrogen bonding between the $2,2^{\prime}$-bipy ligands of the adjacent nets. $\mathrm{H} \cdots \pi$ (ring $M$ ) separations are $2.544(4)$ and $2.977(4) \AA$. As mentioned above, this interaction causes the pyridyl rings ( $M$ and $N$ ) of the $2,2^{\prime}$-bipy ligands to not be coplanar but be twisted by $23.6(1)^{\circ}$. The interactions observed in $4 d$ presumably assist the formation interpenetrated nets, similar to the triple interpenetrated 3-D SCO polymers of $\left[\mathrm{Fe}(\mathrm{pmd})\left(\mathrm{H}_{2} \mathrm{O}\right)\left\{\mathrm{M}(\mathrm{CN})_{2}\right\}_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$, where pmd $=$ pyrimidine, $\mathrm{M}=\mathrm{Ag}$ or

Au (Neil et al., 2003). Indeed, it is possible that the Fe(II) analogues of $\mathbf{4 d}$ would show SCO features.

(a)

(b)

Figure 4.18 (a) Ball and stick and (b) space-filling representations of the interpenetrating nets along the $b$ axis of $\mathbf{4 d}$, the alternating frameworks are shown in yellow, red and green. The $2,2^{\prime}$-bipy molecules are omitted for clarity.

In addition, although these 1-D channels of single 3-D nets have significant size, despite the occurrence of interpenetration of second and third 3-D nets which reduces the void volume, there is no significant void space as calculated by PLATON (Spek, 1995).

(a)

(b)

Figure 4.19 Views of a fragment of the alternating nets in $\mathbf{4 d}$ showing (a) the $\mathrm{Ag} \cdots \mathrm{Ag}$ argentophilic and (b) $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ interactions (dotted lines).

### 4.3.6 Magnetic Properties of $\left[\mathrm{Ag}(\mathrm{CN})_{2} \mathbf{M n}\left(2,2^{\prime}-\text {-bipy }\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathrm{Ag}(\mathrm{CN})_{2}(\mathbf{4 b})$

Complex 4b shows a Curie-Weiss dependence of $\chi_{\mathrm{Mn}}$ versus temperature as shown in Figure 4.20, with the corresponding $\mu_{\text {eff }}$ values being independent of temperature, $5.8 \mu_{\mathrm{B}}$, indicating no spin-spin coupling is occurring in agreement with the crystal structure.

Figure 4.20 Plot of magnetic moment in field of 1 T for $\mathbf{4 b}$. The solid lines are not calculated plots.

### 4.4 Conclusions

At a synthetic level, the used of a $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}: \mathrm{M}^{\mathrm{II}}: 2,2^{\prime}$-bipy mole ratio of 1:1:1 led in only one case, $\mathbf{4 d}$, to the stoichiometry $\mathrm{M}^{\mathrm{II}}: 2,2^{\prime}$-bipy of $1: 1$, desired in the aim of making square tube topologies. The other compounds, $\mathbf{4 a}-\mathbf{4 c}$, all crystallized with the cis-(2,2'-bipy $)_{2} \mathrm{M}$ fragments in mononuclear or polynuclear compounds, showing that this is a stable moiety. Perusal of Figure 4.15 show that, in $4 d$ the square "rings" have the four cis-oriented $\left[\mathrm{Ag}(\mathrm{CN})_{2}\right]^{-}$group required to construct
tubes. However, because the $2,2^{\prime}$-bipy chelates are not all on the "outer" blocking position of each square, this allows bridging to continue to join the squares, "side ways", into extended grids. In the cis-(2,2'-bipy) ${ }_{2} \mathrm{M}$-containing species $\mathbf{4 a}-\mathbf{4 c}$, the tubes can not, of course, form.

Despite this, the $\left[\operatorname{Ag}(\mathrm{CN})_{2}\right]^{-}$is a useful building block for the construction of various supramolecular coordination polymers. Among the four complexes, argentophilic $(\mathrm{Ag} \cdots \mathrm{Ag})$ and other noncovalent interactions of $\mathrm{Ag} \cdots \mathrm{N}, \mathrm{Ag} \cdots \pi$, strong (O-H $\cdots \mathrm{N}$ ) or weak $(\mathrm{C}-\mathrm{H} \cdots \mathrm{O}, \mathrm{C}-\mathrm{H} \cdots \pi)$ hydrogen bonds and $\pi \cdots \pi$ interactions have an impact on the overall structures as well as playing important roles in increasing supramolecular structural dimensionality.

The influence of $\mathrm{Ag} \cdots \mathrm{N}$ and $\mathrm{Ag} \cdots \mathrm{Ag}$ interactions is apparent on the structures of $\mathbf{4 a}$ and $\mathbf{4 b}$, respectively, which increase in dimensionality from 0 - to 1-D chains. In both complexes, dimensionality is then increased from 1-D chain to 3-D supramolecular network via hydrogen bonds and $\pi \cdots \pi$ interactions. $\mathbf{4 c}$ and $\mathbf{4 d}$ are novel heterobimetallic $\mathrm{Cd}(\mathrm{II})-\mathrm{Ag}(\mathrm{I})$ cyano bridged coordination polymers. The former forms a 1-D ladder like structure and the latter consists of triply interpenetrating square-grid nets. Although $4 \mathbf{c}$ displays no $\mathrm{Ag} \cdots \mathrm{Ag}$ interactions, there are $\mathrm{Ag} \cdots \pi, \mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\pi \cdots \pi$ interactions cross-linked between the 1-D thus yielding a 3-D supramolecular structure. Triply interpenetrated 3-D nets of 4d are stabilized by a number of $\mathrm{Ag} \cdots \mathrm{Ag}$ contacts as well as weak $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \pi$ interactions. Paramagnetic behaviour with zero antiferromagnetic coupling has been observed in 4b, in accord with the long $\mathrm{Mn}^{\mathrm{II}}-\mathrm{NC}-\mathrm{Ag}^{\mathrm{I}}-\mathrm{CN}-\mathrm{Mn}^{\mathrm{II}}$ covalent bridging. The $\mathrm{Mn}^{\mathrm{II}}-\mathrm{NC}-\mathrm{Ag}^{\mathrm{I}}-\mathrm{CN}-\left(\mathrm{H}_{2} \mathrm{O}\right)-\mathrm{Mn}^{\mathrm{II}}$ bridges in $4 \mathbf{b}$, were not conducive to spin-spin coupling.

## CHAPTER V

## SYNTHESIS, STRUCTURE, AND

## MAGNETIC PROPERTIES OF 3-D CYANIDE-BRIDGED HOMOMETALLIC COORDINATION POLYMERS

### 5.1 Introduction

The design and synthesis of polymeric cyano bridged metal complexes has received much attention over the past three decades due to their interest in the fields of magnetic (Verdaguer et al., 1999; Ohba and Ōkawa, 2000, Černák et al., 2002), electrochemical (Karyakin, 2001), and microporous features (Hoskins and Robson, 1990; Zheng et al., 2005; Kepert, 2006; Chapman and Chupas, 2007). The diamagnetic, square-planar anions $\left[\mathrm{M}(\mathrm{CN})_{4}\right]^{2-}$, where $\mathrm{M}=\mathrm{Ni}$, Pt , and Pd, are ideal building blocks for constructing of coordination polymers, due to the ability of the four cyanide groups to connect to other metal atoms, and thus build up molecular assemblies either heterometallic or homometallic with various degrees of dimensionality (Muga et al., 2004). Among such materials were the first 2-D Hofmann-like structures of formula $\left[\mathrm{Fe}(\mathrm{py})_{2} \mathrm{Ni}(\mathrm{CN})_{4}\right]$, where $\mathrm{py}=$ pyridine, exhibiting spin-crossover (SCO) properties (Kitazawa et al., 1996). In this system, the $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ moiety acts as an anionic "ligand" in the related fashion to the anionic ligand $\mathrm{NCS}^{-}$observed, for example, in 3-D structure of iron(II) SCO compounds of $\left[\mathrm{Fe}_{2}(\text { azpy })_{4}(\mathrm{NCS})_{4}\right] \cdot($ guest $)$, azpy $=$ trans-4,4'-azopyridine $(H a l d e r ~ e t ~ a l ., ~ 2002) . ~$

Following this early work by Kitazawa et al and Real et al reported the use of 2connecting pyridine ligands such as pyrazine to increase the dimensionality of coordination polymers, resulting in 3-D Hofmann structures of the type $\left[\mathrm{Fe}(\right.$ pyz $\left.) \mathrm{M}^{\mathrm{II}}(\mathrm{CN})_{4}\right]$, where pyz $=$ pyrazine, $\mathrm{M}^{\mathrm{II}}=\mathrm{Ni}, \mathrm{Pd}$, Pt (Niel et al., 2001; Bonhommeau et al., 2005). Similar structural motifs were obtained when aliphatic bidentate amines were used in the $\mathrm{Cd}-\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ system (Kitazawa et al., 1991). These pyrazine-bridged compounds have similar cooperative SCO properties and characteristic change of color upon spin change, and to the pyridine 2-D species. From a reactivity point of view, Iwamoto and co-workers showed that the rigidity of the Hofmann type clathrate frameworks allows for shape and size selective inclusion of organic solvents or water molecules to fill up the void space stabilizing the crystal structure. The absorption and/or desorption of guest molecules may reveal potential applications in the areas of separation and catalysis (Nishikiori and Iwamoto, 1986; Park and Iwamoto, 1992; Yuge and Iwamoto, 1993; 1994; Yuge et al., 1995; Yuge, Noda and Iwamoto, 1996).

The tetracyanometallate moieties (generally formed by $\mathrm{d}^{8}$ metal ions) are lowspin and diamagnetic, and thus cannot exhibit intrinsic spin and magnetic properties as do the $S=1 / 2$ entities such as $\mathrm{d}^{5}$ (low-spin) $\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{CN})_{6}\right]^{3-}$. Therefore, from a magnetic point of view, the use of $\left[\mathrm{M}^{\mathrm{II}}(\mathrm{CN})_{4}\right]^{2-}$ building blocks has received little attention for designing magnetically ordered coordination polymers, but they can provide second neighbor magnetic interactions across the five atom $\mathrm{NC}-\mathrm{Ni}-\mathrm{CN}$ bridge. Importantly, the cyanide ligand can also participate in noncovalent interactions such as hydrogen bonding and weaker electrostatic contacts. It has been suggested that hydrogen bonds and $\pi-\pi$ interactions between neighbouring aromatic
rings may serve as weak exchange pathways between paramagnetic centers (Goodson et al., 1994; Van Langenberg et al., 1997). Such a situation was observed in the complex $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Cu}(\mathrm{en})_{2}\right]$, where en $=1,2$-diaminoethane (Oredáč et al., 1995). This compound has structure consisting of 1-D 2,2-TT chains of composition $\left[-\mathrm{Cu}(\mathrm{en})_{2}-\mathrm{N} \equiv \mathrm{C}-\mathrm{Ni}(\mathrm{CN})_{2}-\mathrm{C} \equiv \mathrm{N}-\right]_{n},(T=$ trans $)$, formed by $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anions linked via two cyano groups in the trans position to $\left[\mathrm{Cu}(\mathrm{en})_{2}\right]^{2+}$ cations. Low-temperature magnetic and thermodynamic studies indicated that this compound behaved as a 2-D magnet in which hydrogen bonds mediate the exchange coupling. Following this example, a series of 1-D cyanide-bridged bimetallic coordination polymers constructed from $\left[\mathrm{M}(\mathrm{CN})_{4}\right]^{2-}$ acting as the bridge between four-coordinate bis(diamine) metal(II) complex, have been structurally and magnetically studied. The most representative examples of these types of complexes were discovered by Černák and co-workers (Černák et al., 2002).

As mentioned in Chapter I (section 1.6) the present work forms part of a research program on the chemistry of cyanide-bridged bimetallic coordination polymers with a primary aim being the synthesis of 1-D tube-like motifs using $\left[\mathrm{M}(\text { bidentate })(\mathrm{CN})_{4}\right]^{2-}$ and $\left[\mathrm{M}(\text { bidentate })(\text { solvent })_{4}\right]^{2+}$ building blocks, where bidentate blocks the 2- and 3-D directions. A more general aim of the project was to study the structural diversity and magnetic properties of cyanide-bridged compounds. In this chapter some novel cyanide-bridged compounds of the types $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right.$ $\mathrm{Ni}(\mathrm{en})] \cdot 2 \mathrm{H}_{2} \mathrm{O}(\mathbf{5 a})$ and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ tn $\left.)\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeOH}(5 b)$, having 3-D homometallic frameworks are described, in which the complex anions $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ was employed as building block. These compounds are formed reproducibly in high yield ( $>80 \%$ ) by a slow diffusion method at room temperature. The $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ compound did not, of
course, contain a bidentate chelate and thus the method could not yield tube-like product. The preparation of these compounds and their magnetostructural investigation are presented here.

### 5.2 Experimental Section

### 5.2.1 Materials and Physical Measurements

$\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{K}[\mathrm{Ni}(\mathrm{CN}) 4] \cdot \mathrm{H}_{2} \mathrm{O}, \quad$ en, and tn were commercially available, and were used without further purification. Precursor complex $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ was prepared according to the method reported in Chapter III.

Caution!: Cyanide containing compounds are very poisonous. Great care was taken so that its salts did not come into contact with acid, which would liberate highly toxic hydrogen cyanide gas. Cyanide salts should not be touched with the fingers, a spatula was used or small pieces with pincers were handled, and reactions were performed under a fume hood.

Microanalytical measurements ( $\mathrm{C}, \mathrm{H}, \mathrm{N}$ ) were performed by Campbell Microanalytical Laboratory, Chemistry Department, University of Otago, Dunedin, New Zealand. Infrared spectra of Nujol mulls were recorded using a diamond-ATR cell on a Bruker Opus/IR IFS 55 spectrometer in the range of $600-4000 \mathrm{~cm}^{-1}$ ( 50 scans, resolution $\pm 4 \mathrm{~cm}^{-1}$ ]. Thermogravimetric analysis (TGA) was performed on a Perkin-Elmer TGA 7 thermogravimetric analyzer in the air with a heating rate of 10 ${ }^{\circ} \mathrm{C} / \mathrm{min}$. Variable-temperature magnetic susceptibility data were obtained by Dr. Boujemaa Moubaraki, Monash University using a Quantum Design MPMS 5 SQUID magnetometer for DC magnetization measurements.

### 5.2.2 Syntheses

## Preparation of $\left[\mathrm{Ni}(\mathrm{CN})_{\mathbf{4}} \mathrm{Ni}(\mathrm{en})\right] \cdot \mathbf{2 \mathrm { H } _ { 2 } \mathrm { O }}$ (5a)

A crystalline sample of $\mathbf{5 a}$ was obtained using a slow diffusion method in which an aqueous solution of 14 mL capacity was contained in an H -shaped tube, and left in the dark. In a typical experiment procedure, $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}(158 \mathrm{mg}, 0.5$ mmol ) was dissolved in 3 mL of distilled water to form a bright blue solution and this was pipetted into one side of the H -tube. $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}(120 \mathrm{mg}, 0.5 \mathrm{mmol})$ was dissolved in 3 mL of distilled water to give a bright yellow solution, and this was pipetted into the other side arm of the H -tube. The H -tube was then carefully filled with distilled water. Upon slow diffusion over a period of two weeks, pink blockshaped single crystals of $\mathbf{5 a}$ were formed in the $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)_{2}$ containing side of the H-tube. Yield: $96 \mathrm{mg}, 80 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{~N}_{6} \mathrm{Ni}_{2} \mathrm{O}_{2}(\mathrm{Mr}=317.59 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 22.89(22.70) ; \mathrm{H}, 3.75(3.81), \mathrm{N}, 26.33$ (26.46). ATR-FTIR ( $v_{\max } / \mathrm{cm}^{-1}$ ): 669w, $959 \mathrm{w}, 1019 \mathrm{~m}, 1070 \mathrm{w}, 1095 \mathrm{w}, 1317 \mathrm{w}, 1395 \mathrm{w}$, $1452 \mathrm{w}, ~ 1597 \mathrm{~s}, 1982 \mathrm{w}, 2163 \mathrm{~s}, 2324 \mathrm{w}, 2867 \mathrm{w}, 2908 \mathrm{w}, 2960 \mathrm{w}, 3189 \mathrm{w}, 3285 \mathrm{~m}$, $3340 \mathrm{~m}, 3580 \mathrm{~m}, 3857 \mathrm{~s} . \mu_{\mathrm{eff}}(300 \mathrm{~K})=3.03 \mu_{\mathrm{B}}$.

## Preparation of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot \mathbf{H}_{\mathbf{2}} \mathrm{O} \cdot \mathbf{M e O H}(5 b)$

A sample of $\mathbf{5 b}$ was prepared following the procedure described above for $\mathbf{5 a}$ using aqueous methanolic $(1: 1, \mathrm{v} / \mathrm{v})$ solutions. Typically, $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(150 \mathrm{mg}$, $0.5 \mathrm{mmol})$ and $\mathrm{tn}(40 \mathrm{mg}, 0.5 \mathrm{mmol})$ were dissolved in 3 mL of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ to form a blue solution of $\left[\mathrm{Ni}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$ (in situ), and this was pipetted into one side of a $\mathrm{H}-$ tube. $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}(120 \mathrm{mg}, 0.5 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ to give a bright yellow solution, and this was pipetted into the other arm. The H-tube was then carefully filled with $\mathrm{MeOH} / \mathrm{H}_{2} \mathrm{O}$ solution. Slow diffusion for two weeks
yielded pink-blue block-shaped crystals of $\mathbf{5 b}$ in the $\left[\mathrm{Ni}(\mathrm{tn})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$ containing side. Yield: $120 \mathrm{mg}, 85 \%$ based on $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$. Anal. Found (calcd) for $\mathrm{C}_{8} \mathrm{H}_{16} \mathrm{~N}_{6} \mathrm{Ni}_{2} \mathrm{O}_{2}(M r=345.64 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 27.68(27.80) ; \mathrm{H}, 4.53(4.67), \mathrm{N}, 24.29$ (24.31). ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 640 \mathrm{w}, 910 \mathrm{~m}, 1016 \mathrm{~m}, 1073 \mathrm{w}, 1140 \mathrm{w}, 1279 \mathrm{w}, 1399 \mathrm{w}$, $1430 \mathrm{w}, 1457 \mathrm{~m}, 1599 \mathrm{~m}, 2158 \mathrm{~s}, 2830 \mathrm{w}, 2871 \mathrm{w}, 2932 \mathrm{w}, 2972 \mathrm{w}, 3272 \mathrm{~m}, 3342 \mathrm{~m}$, $3455 w, 3549 w, 3616 w . \mu_{\text {eff }}(300 K)=2.99 \mu_{\mathrm{B}}$.

### 5.2.3 X-Ray Crystallographic Study

Single crystals with dimensions $0.12 \times 0.14 \times 0.20 \mathrm{~mm}(\mathbf{5 a})$ and $0.08 \times 0.14 \times$ 0.26 mm (5b) were mounted on a MiTeGen MicroMounts fiber in a small amount of oil and quench cooled to $123(2) \mathrm{K}$ prior to measurements made by Dr. Suzanne M. Neville, Monash University. Reflection intensities were collected on a Bruker X8 APEX CCD diffractometer (Mo $K_{\alpha}$ radiation, $\bar{\lambda}=0.71073 \AA$ ) and equipped with an Oxford Instruments nitrogen gas Cryostream. Empirical absorption corrections were applied to all data using SADABS (Blessing, 1995). The structures were solved using SHELXS-97 (Sheldrick, 1997) and refined on $F^{2}$ using SHELXL-97 (Sheldrick, 1997) with X-SEED (Barbour, 2001) as a graphics interface.

In the final model all non-hydrogen atoms were given anisotropic atomic displacement parameters. For 5a, hydrogen atoms attached to oxygen atoms of the water molecules were located in a difference Fourier map and were isotropically. Hydrogen atoms bound to carbon or nitrogen atoms of en molecule were positioned geometrically and refined as riding atoms with $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ distances of 0.97 and $0.86 \AA$, respectively, and $U_{\text {iso }}(\mathrm{H})$ values of $1.2 U_{\text {eq }}(\mathrm{C}, \mathrm{N})$. In compound $\mathbf{5 b}$, the tn molecule exhibits disorder across the pseudo mirror plane with refined occupancies of approximately 1:1. Standard DFIX and SIMU restraints were used for the dimensions
of the disordered tn molecule. The disorder in hydrogen occupancy on this tn molecule was refined using two hydrogen atom sites and the correct geometry was induced using DFIX and DANG restraints (Shelxl-97). A DFIX restraint was also used to refine the hydrogen atoms of water and methanol molecules. Crystal data and details of the data collection, and structure refinement are summarized in Teble 5.1. Selected interatomic bond lengths and angles for compounds $\mathbf{5 a}$ and $\mathbf{5 b}$ are given in Teble 5.2. Intra- and intermolecular hydrogen bonds in compounds are provided in Teble 5.3.

### 5.3 Results and Discussion

### 5.3.1 Syntheses

The compounds $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (5a) and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot$ $\mathrm{MeOH} \cdot \mathbf{( 5 b})$ were synthesized (close to quantitatively) by slow evaporation of aqueous solution for $\mathbf{5 a}$, and an aqueous/methanolic ( $1: 1, \mathrm{v}, \mathrm{v}$ ) solution for $\mathbf{5 b}$. Hshaped tubes were employed, and left in the dark at room temperature. The syntheses involved equations 1 and 2 , respectively.

Attempts to grow single crystals of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in aqueous solution using the same procedure as in $\mathbf{5 a}$ were unsuccessful. So the mixed solvent was used. Change of counter ions from $\mathrm{Ni}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ to $\mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ does not have any significant effect on the nature of the products, provided the reactant ratios of 1:1 remain the same. This is perhaps not surprising since anions are not in the product. More significantly, the dimensionality of cyanide-bridged homometallic coordination polymers in the $\mathrm{Ni}(\mathrm{CN})_{4}-\mathrm{Ni}-\mathrm{L}$ system (where $\mathrm{L}=$ en or tn ) is increased by controlling the stoichiometry of $\mathrm{Ni}: \mathrm{L}$. In the present system, the reaction of $\mathrm{L}: \mathrm{Ni}: \mathrm{Ni}(\mathrm{CN})_{4}$ in the molar ratio of 1:1:1 yielded 3-D network structures in $\mathbf{5 a}$ and $\mathbf{5 b}$ (below). In contrast, Černák and co-workers used 2 mole equivalents of en per Ni , $\left[\mathrm{Ni}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]^{2+}$, and obtained coordination polymers containing 1-D chains of $\left.\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right\}\right]$. At higher en: Ni ratios $\left.(1: 3),\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{3}\right\}\right]$ was produced (Černák et al., 2002).

### 5.3.2 Structural Description of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})\right] \cdot \mathbf{2 \mathrm { H } _ { 2 } \mathrm { O }}(\mathbf{5 a})$

Compound 5a crystallizes in the monoclinic system with space group $C 2 / c$ (No. 15). The structure is a neutral 3-D nickel cyanide framework. The detailed coordination environments for both kinds of metal ions in the lattice are shown in Figure 5.1. The asymmetric unit contains nine non-hydrogen atoms with two crystallographically distinct Ni atoms. Atoms Ni 1 and Ni 2 lie on 2-fold rotation axes
and inversion centers, respectively. The uncoordinated lattice water molecule lies on a general position.

Figure 5.1 View of 5a with the atom-numbering scheme. Displacement ellipsoids are draw at the $50 \%$ probability level. Hydrogen atoms are shown as small spheres of arbitrary radii. Symmetry codes: (i) $0.5-x, 0.5-y, 1-z$; (ii) $-x$, $y, 0.5-z$; (iii) $0.5+x, 0.5+y, z$; (iv) $0.5-x, 0.5+y, 0.5-z$; (v) $-x, y, 0.5-z$.

The central Nil atom exhibits octahedral geometry. Of the six nitrogen atoms, four positions are occupied in the equatorial plane by two bridging cyano groups and a chelating en molecule. The remaining two nitrogen atoms belong to two N -bonded bridging cyano groups situated in the axial sites. The chelating en molecule has the gauche conformation. The angle between the planes $\mathrm{N} 2-\mathrm{Ni} 1-\mathrm{N} 2^{\mathrm{i}}$ and $\mathrm{C} 3-\mathrm{Ni} 1-\mathrm{C} 3^{\mathrm{i}}$ (symmetry operation: (i) $-x, y, 0.5-z$ ) is $28.3(1)^{\circ}$. This value is comparable with the value of $24.1(8)^{\circ}$ and $25.6(7)^{\circ}$ observed in $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right] \cdot 2.16 \mathrm{H}_{2} \mathrm{O}$ (Černák et al., 1990), and $29.6(3)^{\circ}$ found for the anhydrous complex $\left.\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right\}\right]$ (Černák et al., 1988). The largest deviation from the least squares plane for Nil through
$\mathrm{N} 1 / \mathrm{N} 1^{\mathrm{i}} / \mathrm{N} 2 / \mathrm{N} 2^{\mathrm{i}}$ is -0.081 (1) $\AA$ at $\mathrm{N} 2^{\mathrm{i}}$ (symmetry operation: (i) $-x, y, 0.5-z$ ). The Ni1 center is exactly located in the plane. The $\mathrm{Ni}-\mathrm{N}_{\text {en }}$ distance of 2.094 (1) $\AA$ is comparable with those observed in the analogues en complexes $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]\left(\mathrm{NO}_{3}\right)$ (McDougall and Hancock, 1980) and $\left[\mathrm{Ni}(\mathrm{en})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \cdot \mathrm{SO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (Healy et al., 1984). Moreover, the distances $\mathrm{Ni}-\mathrm{N}_{\mathrm{en}}$ are a little shorter than the bond distances of the same type in some bis(en), $\left[\mathrm{Ni}(\mathrm{en})_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\mathrm{ClO}_{4}\right]_{2}$ (Minacheva et al., 1974), or tris(en), $\left.\left[\mathrm{Ni}(\mathrm{en})_{3}\right]\left[\mathrm{NO}_{3}\right)_{2}\right]$ (Korp et al., 1980) complexes. This means that the en ligand in compound 5a is bonded more strongly than in bis(en) or tris(en) complexes. The $\mathrm{Ni}-\mathrm{N}_{\mathrm{CN}}$ distances exhibit different values. Namely, the $\mathrm{Ni}-\mathrm{N} 1$ bonds (2.064(1) $\AA$ ) in the cis position with respect to the bridging cyano groups are somewhat shorter compared to that in the trans position of $\mathrm{Ni}-\mathrm{N} 3$ (2.092(1) $\AA$ ). A similar elongation of the trans-positioned bonds versus cis-positioned bonds was observed the $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right]$, (Černák et al., 1988) and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{M}(\mathrm{en})_{2}\right]_{2}\left(\mathrm{PhNH}_{2}\right)$, where $\mathrm{M}^{\mathrm{II}}=$ $\mathrm{Cd}, \mathrm{Zn}, \mathrm{Cu}$ and Ni (Yuge and Iwamoto, 1994).

The overall mean $\mathrm{C} \equiv \mathrm{N}$ bond length of $1.149(2) \AA$ is also in accordance with the sum of the triple bond radii of C and N atoms ( 0.603 and $0.55 \AA$, respectively) found in the work of Pauling (1960). Looking at the $\mathrm{Ni}-\mathrm{N} \equiv \mathrm{C}$ angle, $\mathrm{Ni} 1-\mathrm{N} 1 \equiv \mathrm{C} 1$ at $174.1(1)^{\circ}$ is less bent than Ni1-N3 $\equiv \mathrm{C} 2,167.1(1)^{\circ}$.

The Ni 2 atom has a $\mathrm{NiC}_{4}$ chromophore, and exhibits a slightly deformed square planar geometry. The maximum deviation of the C atoms from the leastsquares plane through the $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ ion (defined by $\mathrm{C} 1 / \mathrm{N} 1 / \mathrm{C} 2 / \mathrm{N} 3 / \mathrm{Ni} 2 / \mathrm{Cl}^{\mathrm{i}}{ }^{1}$ $\mathrm{N} 1^{\mathrm{i}} / \mathrm{C} 2^{\mathrm{i}} / \mathrm{N} 3^{\mathrm{i}}$ (symmetry operation: (i) $0.5-x, 0.5-y, 1-z$ ) is $0.489(2) \AA$ for $\mathrm{C} 1^{i}$. This means that the $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion is not quite as planar as in the compound $\mathrm{Na}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, the largest deviation in that plane being $0.027 \AA$ at 295 K and
$0.022 \AA$ at 30 K (Ptasiewicz-Bak et al., 1998). Comparison of the structural parameters of the $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion with other tetracyanonickelates(II) complexes shows that the bond lengths and angles have typical values, and are similar to those found in $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right]$ and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right] \cdot 2 \cdot 16 \mathrm{H}_{2} \mathrm{O}$ complexes, reported by Černák and co-workers (1988; 1990).

Figure 5.2 The 2-D sheet motif in 5a. Hydrogen atoms and water molecules are omitted for clarity.

Figure 5.3 Projection of the 3-D network structure of 5a viewed slightly offset from the $c$ axis, en molecules are omitted.

Each $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ is coordinated to four $[\mathrm{Ni}(\mathrm{en})]^{2+}$ cations through four cyano nitrogen atoms to form a 2-D sheet motif with alternating fused rows of twenty fourmember $\mathrm{Ni}_{8}(\mathrm{CN})_{8}$ rings and square shaped $\mathrm{Ni}_{4}(\mathrm{CN})_{4}$ rings, as shown in Figure 5.2. This topology is similar to that found in $\left[\mathrm{NdM}(\right.$ bpym $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(\mathrm{CN})_{6}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$, where bpym $=2,2^{\prime}-$ bipyrimidine, $\mathrm{M}=\mathrm{Fe}$ and Co (Ma et al., 2001). Within this arrangement, the $\mathrm{Ni} \cdots \mathrm{Ni}$ distance across the cyanide ligands is $5.0613(3) \AA$. The shortest $\mathrm{Ni} \cdots \mathrm{Ni}$ distances across the square rings of the sheets are $15.5247(7)$ and 16.3115(7) $\AA$ for Ni1 $\cdots \mathrm{Ni} 1^{\mathrm{i}}$ and $\mathrm{Ni} 2 \cdots \mathrm{Ni} 2{ }^{\text {ii }}$ (symmetry codes: (i) $1-x, 1-y,-z$; (ii) $0.5+x, 0.5+y,-1+z$ ), respectively. As shown in Figure 5.3, the overall 3-D network is generated by these 2-D sheets being mutually connected to neighbouring sheets through $\mathrm{Ni} 2-\mathrm{C} 1 \equiv \mathrm{~N} 1$
-Ni1 linkages. Water molecules are located in the lattice, and the cavities are filled by the coordinated en ligands (not shown in Figure). In addition, each nickel center acts as four-connected node and gives a binodal network with the Schläfli symbol $\left(4^{2} .8^{4}\right)\left(4^{2} .8^{4}\right)($ Batten and Robson, 1998).

Figure 5.4 The detailed view of the hydrogen bonds in the 5a. Hydrogen bonds are represented by dotted lines.

As stated previously, hydrogen bonds may serve as an exchange pathway between paramagnetic centers. The observed intra- and intermolecular hydrogen bonds are given in Teble 5.3. As shown in Figure 5.4, atom N2 in the coordinated en ligand forms hydrogen bonds to atom O1 of the solvent water molecule with distances of $3.078(3)$ and $3.272(3) \AA$. The $\mathrm{N} 2-\mathrm{N}-\mathrm{O} 1$ angle is $c a .160^{\circ}$. In turn, atoms H 1 a and H 1 b of the water molecule $(\mathrm{O} 1)$ are oriented perpendicular to the mid-point (A) of the $\mathrm{C} 1 \equiv \mathrm{~N} 1(0.5+x, 0.5+y, z)$ and $\mathrm{C} 2 \equiv \mathrm{~N} 3(0.5-x, 1.5-y, 1-z)$ at 2.82 and $2.04 \AA$
for $\mathrm{H} 1 \mathrm{a} \cdots A(\mathrm{C} 1 \equiv \mathrm{~N} 1)$ and $\mathrm{H} 1 \mathrm{~b} \cdots A(\mathrm{C} 2 \equiv \mathrm{~N} 3)$, respectively. The $\mathrm{O} 1-\mathrm{H}-A$ angle is in between 146 and $147^{\circ}$. These observed distances and angles are suggesting weak interactions with the $\pi$ molecular orbital of the cyano groups at the limited of such interactions (Saenger and Jeffrey, 1991), with the $\mathrm{C} 2 \equiv$ N3 interaction being considering stronger.

### 5.3.3 Structural Description of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathbf{M e O H}(5 \mathrm{~b})$

Compound $\mathbf{5 b}$ crystallizes in the tetragonal system with space group $P 4 m b m$ (No. 127). The asymmetric unit with the atom-numbering scheme is shown in Figure 5.5, and consists of a half $[\mathrm{Ni}(\mathrm{tn})]^{2+}$ cation, half a $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anion $(0.25 \mathrm{Ni} 2,0.25$ $\mathrm{Ni} 3)$, and isolated disordered water and methanol molecules.

Nil exhibits a distorted $\mathrm{NiN}_{6}$ octahedral geometry, coordinating to two nitrogen atoms from the chelating tn ligand $\left(\mathrm{Ni}-\mathrm{N}_{\mathrm{tn}}=2.100(3) \AA\right)$, and four cyano groups atoms $\left(\mathrm{Ni}^{-}-\mathrm{N}_{\mathrm{tn}}=2.075(3)\right.$ and 2.078(3) $\left.\AA\right)$. The chelating tn molecule is disordered about a crystallographic mirror plane with equal site occupation factors. The $\mathrm{Ni}-\mathrm{N} \equiv \mathrm{C}$ bond angles fall into two groups. $\mathrm{Ni} 1-\mathrm{N} 2 \equiv \mathrm{C} 1$ is nearly linear $\left(176.7(2)^{\circ}\right)$, whereas Ni1-N3 $\equiv \mathrm{C} 2$ deviates significantly from linearity $\left(163.4(3)^{\circ}\right)$. Ni2 and Ni3 are located on special positions ( $0,1 / 2,1 / 2$ ) and ( $0,0,0$ ), respectively. Each Ni2 ion is coordinated by four cyanide ligands in a square planar arrangement. All four of the cyanide groups then bridge to the Nil atoms. The Ni2-C bond distance is $1.864(3) \AA$. This value is normal and comparable to that observed in $\mathbf{5 a}$, and those reported for other the bimetallic complexes of $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ building blocks, such as $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right]$ and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})_{2}\right] \cdot 2.16 \mathrm{H}_{2} \mathrm{O}$ (C̆ernák et al., 1988; 1990). The $\mathrm{Ni}-\mathrm{C} \equiv \mathrm{N}$ bond angles are almost linear and range from 177.3(3) to $179.0(3)^{\circ}$,
indicative of strong directional bonding as the $\pi$ orbitals of the cyano ligands interact with the d orbitals of the metal center. The average $\mathrm{C} \equiv \mathrm{N}$ bond length of $1.150(3) \AA$ is found to be similar to that in $\mathbf{5 a}$.

Figure 5.5 Perspective view of part of the structure in $\mathbf{5 b}$ showing coordination environments around the Ni metals. Displacement ellipsoids are draw at the $50 \%$ probability level. Hydrogen atoms are shown as small spheres of arbitrary radii. Symmetry codes: (i) $-x, 1-y,-z$; (ii) $1-x, y, z$; (iii) $x$, $-y, 1$; (iv) $x, y,-1+z$; (v) $x, 1+y, z$; (vi) $-1 / 2+x, 1 / 2-y,-z$; (vii) $1 / 2+x$, $1 / 2-y,-z$.

As depicted in Figure 5.6, the structure of compound $\mathbf{5 b}$ contains pairs of $[\mathrm{Ni}(\mathrm{tn})]^{2+}$ cationic groups bridged by $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ anions in a cis fashion, generating $\left[\mathrm{Ni}_{2}-\mathrm{Ni}_{2}\right]$ squares with the $\mathrm{Ni} 1 \cdots \mathrm{Ni} 2$ distance across the cyanide ligands being 5.0914(4) $\AA$. Each square is linked to another two others through shared Ni2 atoms, creating a 1-D chain parallel to the crystallographic $c$ axis. These 1-D chains are further connected by Ni1- $\mathrm{C}=\mathrm{N}-\mathrm{Ni} 3$ linkages along the crystallographic $a$ axis with a Ni1 $\cdots \mathrm{Ni} 3$ distance of $5.0320(2) \AA$, to create a column network as shown in Figure 5.7. Within the column, the shortest intermolecular $\mathrm{Ni} \cdots \mathrm{Ni}$ distances are $7.3909(10)$, 9.8784(5), and $7.0038(4) \AA$ for $\mathrm{Ni} 1 \cdots \mathrm{Ni}^{\mathrm{i}}, \mathrm{Ni} 1 \cdots \mathrm{Ni}^{3}{ }^{\mathrm{i}}$, and $\mathrm{Ni} 2 \cdots \mathrm{Ni} 2^{\mathrm{ii}}$ (symmetry codes: (i) $-x, 1-y, z$; (ii) $x, y,-1+z$ ), respectively. The underlying net is a trinodal 4connected net with the Schläfli symbol $\left(4^{2} .8^{4}\right)\left(4.6^{5}\right)_{2}\left(6^{4} .8^{2}\right)$, where the symbols represent the nodes in the order Ni2, Ni1, and Ni3. The 3-D network structure in $\mathbf{5 b}$ viewed from an angle slightly displaced from the crystallographic $c$ axis is depicted in Figure 5.8.

Figure 5.6 View of 1-D of a square shaped $[\mathrm{Ni}-\mathrm{Ni}]$ core in $\mathbf{5 b}$ parallel to the $c$ axis.

Figure 5.7 Perspective view of column structure in $\mathbf{5 b}$ along the $c$ axis.

Figure 5.8 Perspective view of the cell packing in 5b along the $c$ axis. Hydrogen atoms and methanol molecules are omitted for clarity.

The crystal structure of $\mathbf{5 b}$ is stabilized by $\mathrm{N} / \mathrm{O} / \mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds and $\mathrm{O}-\mathrm{H} \cdots \pi$ interactions, Table 5.3. As can be seen in Figure 5.9, the hydroxyl groups of the methanol (O1) act as hydrogen bond donor to the oxygen atom of lattice water (O2) molecules $\left(\mathrm{O} 1-\mathrm{H} 1 \mathrm{a} \cdots \mathrm{O} 2^{\mathrm{i}}=2.847(9) \AA\right.$, symmetry code: $\left.(\mathrm{i})-x, y, z\right)$, and also act as a hydrogen bond acceptors toward nitrogen (N1) and carbon atoms (C3) of the tn ligands $\left(\mathrm{N} 1-\mathrm{H} 1 \mathrm{a} \cdots \mathrm{O} 1=3.060(5) \AA, \mathrm{C} 3-\mathrm{H} 3 \mathrm{~b} \cdots \mathrm{O}^{\mathrm{i}}=3.315(6) \AA\right.$, symmetry code: (i) $0.5-x, 0.5-y, 1-z$ ). Atom H 2 of the water molecule (O2) is oriented perpendicular to the mid-point $(A)$ of the $\mathrm{C} 1 \equiv \mathrm{~N} 1(x, y, z)$ and $\mathrm{C} 2 \equiv \mathrm{~N} 3(x, y,-z)$ cyanide groups. The $\mathrm{H} 2 \cdots A$ bond lengths and the $\mathrm{O} 2-\mathrm{H} 2-A$ angles are $2.50(8) \AA, 145(7)^{\circ}$ and $3.06(8) \AA$, $117(8)^{\circ}$ for $\mathrm{O} 2-\mathrm{H} 2 \cdots A(\mathrm{C} 1 \equiv \mathrm{~N} 1)$ and $\mathrm{O} 2-\mathrm{H} 2 \cdots A(\mathrm{C} 2 \equiv \mathrm{~N} 3)$, respectively. These values may be considered as weak $\mathrm{O}-\mathrm{H} \cdots \pi$ interactions (Saenger and Jeffrey, 1991).

Figure 5.9 The detailed view of the hydrogen bonds in $\mathbf{5 b}$. Hydrogen bonds are represented by dotted lines.

The network structures of these two compounds are completely different as schematic depicted shown in Figure 5.10. Despite the similar formulae, the size of the aliphatic diamine ligand and the solvated molecules influences the orientations of the linkages, generating different networks for these two compounds.

### 5.3.4 Magnetic Properties

Variable temperature magnetic susceptibility data for polycrystalline samples of $\mathbf{5 a}$ and $\mathbf{5 b}$ were collected in the temperature range $4-300 \mathrm{~K}$. The magnetic behaviours of $\mathbf{5 a}$ and $\mathbf{5 b}$ are very similar. Plots of magnetic behaviours in $\mathbf{5 a}$ and $\mathbf{5 b}$ are shown in Figure 5.11, in the form of the molar magnetic susceptibility $\left(\chi_{M}{ }^{-1}\right)$ or effective magnetic moment ( $\mu_{\text {eff }}$ ) per $2 \mathrm{Ni}^{\text {II }}$, versus the temperature.

DC magnetic susceptibilities were measured in a field of 1 T . The observed value of $\mu_{\text {eff }}$ per $\left\{2 \mathrm{Ni}^{\mathrm{II}}\right\}$ unit at 300 K is $3.03 \mu_{\mathrm{B}}$, where $\mu_{\mathrm{B}}=$ the Bohr magneton $\left(\chi_{\mathrm{M}} T\right.$ $\left.=1.15 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $\mathbf{5 a}$ and $2.99 \mu_{\mathrm{B}}\left(\chi_{\mathrm{M}} T=1.12 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}\right)$ for $\mathbf{5 b}$, which is expected for the magnetically dilute system consisting of square planar $\mathrm{Ni}^{\mathrm{II}}(S=0)$ and octahedral $\mathrm{Ni}^{\mathrm{II}}(S=1)$. These $\mu_{\text {eff }}$ values for $\mathbf{5 a}$ and $\mathbf{5 b}$ are slightly higher than those observed for the 1-D compounds: $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{pn})_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}\left(2.75 \mu_{\mathrm{B}}\right),\left[\mathrm{Ni}(\mathrm{CN})_{4}\right.$ $\left.\mathrm{Ni}(\mathrm{tn})_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O} \quad\left(2.75 \mu_{\mathrm{B}}\right), \quad\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ dien $\left.\left.)\right\}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O} \quad\left(2.78 \mu_{\mathrm{B}}\right)$, and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}\right.$ (trien) $] \cdot \mathrm{H}_{2} \mathrm{O}\left(2.80 \mu_{\mathrm{B}}\right)$ at room temperature, where $\mathrm{pn}=1,2$-diaminopropane, $\mathrm{tn}=1,3-$ diaminopropane, dien $=$ diethylenetriamine, and trien $=$ triethylenetetraamine $($ Zhan et al., 2000). On lowering the temperature, the $\mu_{\text {eff }}$ values for the compounds remain almost constant until 50 K , then decreases gradually in the $50-15 \mathrm{~K}$ range, and finally decreases sharply to reach 2.77 and $2.57 \mu_{\mathrm{B}}$ at 4 K for $\mathbf{5 a}$ and $\mathbf{5 b}$, respectively, the sharp decrease being due to zero-field split of $S=1$ states. The $1 / \chi_{\mathrm{M}}$ versus $T$ plot obeys the Curie-Weiss law, $\chi_{\mathrm{M}}=C /(T-\Theta), C=0.56$ and $0.41 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$, with a negative Weiss constant $(\Theta)=-0.48$ and -0.37 K for $\mathbf{5 a}$ and $\mathbf{5 b}$, respectively. These results might indicate the existence of a weak antiferromagnetic interaction. No differences between the magnetization $(M)$ in zero-field cooling (ZFCM) and in fieldcooling (FCM) samples are observed down to 4 K for both compounds, which
indicates that no long-range magnetic ordering occurs, at leas above 4 K . This is not surprising considering the long $\mathrm{Ni}^{\mathrm{II}}(S=1)-\mathrm{NC}-\mathrm{Ni}^{\mathrm{II}}(S=0)-\mathrm{CN}-\mathrm{Ni}^{\mathrm{II}}(S=1)$ pathway which will lead to very weak coupling. The $\mathrm{Ni}^{\mathrm{II}}(S=1) \cdots \mathrm{Ni}^{\mathrm{II}}(S=1)$ distances in both compounds are approximately $10.1 \AA$.

Figure 5.11 Temperature dependent magnetic behaviours of (a) 5a and (b) 5b.

### 5.3.5 ATR-FTIR Spectra

Comparison of the infrared spectral patterns for compounds $\mathbf{5 a}, \mathbf{5 b}$, and the precursor $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ are shown in Figure 5.12. The assignments of the vibrational bands of these compounds are given in the Table 5.4. The IR spectra of the $\mathrm{Ni}(\mathrm{CN})_{4}$ group in the clathrate, $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ dabn $\left.\left.)\right\}\right] \cdot 1.5$ benzene (Kasap and Özcelík, 1997), and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ dapn $\left.)\right] \cdot$ Toluene (Kasap et al., 1998) are also listed in Table 5.4 for comparison.

In the solid state spectra, the infrared spectral features of the compounds $\mathbf{5 a}$ and $\mathbf{5 b}$ in the range 3000 to $600 \mathrm{~cm}^{-1}$ are similar to each other. Strong absorption band at 2162 and $2154 \mathrm{~cm}^{-1}$ observed in the IR spectrum are assigned to the bridging cyano groups for $\mathbf{5 a}$ and $\mathbf{5 b}$, respectively. Typically, bridging CN ligands have higher stretching frequencies than the terminal CN ligand (Nakamoto, 1963). As expected, the CN stretching band is shifted to higher wavenumbers than those for the free $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ when a CN group is bridged to a second metal. Such frequency shifts were also observed for other compounds which all of the CN group of square planar $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$ moiety were coordinated with a second metal (Kasap et al., 1997; Demirci, and Kantarci, 1998). Broad absorption bands at $3460-3185 \mathrm{~cm}^{-1}$ for $\mathbf{5 a}$ are assigned to $v(\mathrm{NH})$ frequencies from $\mathrm{NH}_{2}$ groups involved in hydrogen bonds (Nakamoto, 1963), for 5a, and a sharp absorption band around $3658-3550 \mathrm{~cm}^{-1}$ is attributed to $v(\mathrm{OH})$ of hydrated water (Sorrell, 1988). The bands appears between 3616 to $3272 \mathrm{~cm}^{-1}$ for $\mathbf{5 b}$ are due to $v(\mathrm{OH})$ from water and methanol molecules. This is consistent with the presence of solvated of water and methanol molecules observed in the single crystal X-ray studies. Broad absorption band at $3480-3160 \mathrm{~cm}^{-1}$ for $\mathbf{5 b}$ are assigned to $v(\mathrm{NH})$ frequencies.

Figure 5.12 ATR-FTIR spectra of $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}, \mathbf{5 a}$ and $\mathbf{5 b}$.

### 5.3.6 Differential Thermal Analysis and Thermal Gravimetric Analysis

Single crystal X-ray structure analysis of compounds $\mathbf{5 a}$ and $\mathbf{5 b}$, reveals that crystallize solvent molecules exist in the lattice (Figures 5.4 and 5.10). From the topological point of view, these solvate molecules have the ability to leave the host lattice. The investigation of inclusion of guest solvent molecules and the thermal stability of the framework in compounds $\mathbf{5 a}$ and $\mathbf{5 b}$, has therefore been monitored by DTA/TGA analysis on polycrystalline sample. The profile consists of two distinguished stages corresponding to the initial release of solvent molecules, and then the organic molecules and cyano groups decomposing. The framework structures of both compounds were found to be stable in the solid state up to $c a .320$ ${ }^{\circ} \mathrm{C}$. The thermal decomposition curve for $\mathbf{5 a}$ and $\mathbf{5 b}$ plotted as a function of temperature versus percent weight loses are shown in Figures 5.13 and 5.14, respectively.

Table 5.4 Vibrational frequencies for compounds $\mathbf{5 a}$ and $\mathbf{5 b}\left(\mathrm{cm}^{-1}\right)$.

| Assignment | $\mathrm{K}_{2}\left[\mathrm{Ni}(\mathrm{CN})_{4}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ | $\mathbf{5 a}$ | $\mathbf{5 b}$ | $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{dabn})\right]^{\mathrm{a}}$ | $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{dapn})\right]^{\mathrm{b}}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $v(\mathrm{OH})$ | $3591 \mathrm{brsh}, 3425 \mathrm{brsh}$ | $3658 \mathrm{vs}, 3580 \mathrm{ssh}$ | $3615 \mathrm{br}, 3549 \mathrm{br}$ | - | - |
| $v(\mathrm{NH})$ | - | $3340 \mathrm{~s}, 3285 \mathrm{~s}, 3189 \mathrm{~m}$ | $3458 \mathrm{sbr}, 3342 \mathrm{~s}, 3272 \mathrm{~m}$ | $3356 \mathrm{~s}, 3294 \mathrm{~s}$ | $3363 \mathrm{~s}, 3298 \mathrm{~m}$ |
| $v(\mathrm{CH})$ | - | $2960 \mathrm{w}, 2911 \mathrm{w}, 2867 \mathrm{w}$ | $2972 \mathrm{wsh}, 2931 \mathrm{wsh}$, | $2950 \mathrm{~s}, 2912 \mathrm{~m}$, | $2954 \mathrm{~s}, 2927 \mathrm{~m}$, |
| $v(\mathrm{C} \equiv \mathrm{N})$ | 2130 vs | 2870 m | 2879 m | $2877 \mathrm{~m}, 2858 \mathrm{~m}$ |  |
| $\delta\left(\mathrm{NH}_{2}\right)$ | - | 2162 vs | 2154 vs | 2169 vs | 2170 vs |
| $\delta\left(\mathrm{CH}_{2}\right)$ | - | 1598 s | 1598 s | 1587 w | 1581 vs |
| $v(\mathrm{CN})$ | - | 1452 w | 1430 w | 1460 m | 1475 m |

The symbols $v$ and $\delta$ to valence and in-plane vibrations, respectively.
$\mathrm{v}=$ very, $\mathrm{s}=$ strong, $\mathrm{m}=$ medium, $\mathrm{w}=$ weak, $\mathrm{br}=$ broad, $\mathrm{sh}=$ shoulder
${ }^{a}\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ dabn $\left.\left.)\right\}\right] \cdot 1.5$ benzene, dabn $=1,4$-diaminobutane (Kasap et al., 1998)
${ }^{b}\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\right.$ dapn $\left.\left.)\right\}\right] \cdot$ Toluene, dapn $=1,5$-diaminopentane (Kasap et al., 1998)

The dehydration process of $\mathbf{5 a}$ is a single step in the range from room temperature to $110{ }^{\circ} \mathrm{C}$. The weight loss is $10.0 \%$ which smaller than the theoretical value of $11.3 \%$, corresponding to the loss of two water molecules. It leads to broad endothermic peaks. The second step has a sharp mass loss and broad endothermic in the $320-417^{\circ} \mathrm{C}$ temperature range. Two for these broader losses occur below $590^{\circ} \mathrm{C}$ the observed total weight loss of $51.9 \%$ in the range $320-590{ }^{\circ} \mathrm{C}$, corresponding to the decomposition of en molecule and cyanides (calculated $51.7 \%$ ), and to the collapse of the framework. The final thermal decomposition product is presumably a mixture of NiO . The total observed weight loss (61.9\%) is in agreement with the calculated (63.4\%).

Figure 5.13 TGA (red) and DTA (blue) profiles for 5a.

Figure 5.14 TGA (red) and DTA (blue) profiles for $\mathbf{5 b}$. The very sharp blue lines of derivative DTA due to the possible moving of sample during heating and should be ignored.

The thermal decomposition of $\mathbf{5 b}$ is similar to the thermal decomposition of 5a and can be described in the same way. In the first endothermic two-stages, broad step observed in the temperature rang $105-280^{\circ} \mathrm{C}$ has a weight loss of $16.1 \%$ due to the loss of solvent water and methanol molecules (calculated 16.0\%). The framework structure of $\mathbf{5 b}$ was found stable in the solid state up to $c a .320{ }^{\circ} \mathrm{C}$ which similar to that found in 5a. The decomposition then proceeds continuously into the second endothermic and sharp step finished at $660^{\circ} \mathrm{C}$. The corresponding observed weight loss of $49.6 \%$ which corresponds to the decomposition of tn molecules and cyanides
(calculated $51.5 \%$ ). The final thermal decomposition product is a mixture of NiO . The total observed weight loss ( $66.1 \%$ ) is in agreement with the calculated one (66.0\%).

### 5.4. Conclusions

Reaction of diamagnetic square-planar complex of tetracyanonickelate(II), $\left[\mathrm{Ni}(\mathrm{CN})_{4}\right]^{2-}$, with $\left[\mathrm{Ni}(\mathrm{L})\left(\mathrm{H}_{2} \mathrm{O}\right)_{n}\right]^{2+}$, where $\mathrm{L}=$ en $(\mathbf{5 a})$ and tn $(\mathbf{5 b})$, provided 3-D cyanide-bridged homometallic coordination polymers of $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{en})\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}(\mathbf{5 a})$ and $\left[\mathrm{Ni}(\mathrm{CN})_{4} \mathrm{Ni}(\mathrm{tn})\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \mathrm{MeOH}(\mathbf{5 b})$. The framework structures of these 3-D species show similar but not identical networks, with some beautiful structural details and hydrogen bonding interactions for solvate molecules. Thermogavimetric studies show that the solvate molecules are removed prior to complex decomposition. These exhibit paramagnetic behavior at the octahedral $\mathrm{Ni}(\mathrm{II})$ centers with little or no spin coupling occurring across either $\mathrm{Ni}(\mathrm{CN})_{4}$ or hydrogen bonding pathways. Further work on such novel framework systems could involve exploration of their porosity and to see if Nil center replaced by $\mathrm{Fe}(\mathrm{II})$ to probably yield 3-D SCO $\left\{\mathrm{FeN}_{6}\right\}$ species somewhat related to Hofmann phases (see also Chapter VI).

## CHAPTER VI

## SYNTHESIS, STRUCTURES,

## AND SPIN-CROSSOVER PROPERTIES OF <br> INFINITE 3-D FRAMEWORK IRON(II) CONTAINING ORGANODINITRILE BRIDGING LIGANDS

### 6.1 Introduction

Prussian blue analogues (PBs) and closely related polymeric metal cyanides have a remarkable history in coordination chemistry and have aroused intensive interest due to their magnetostructural feature and potential application in many fields (Itaya et al., 1986; Ohba and Ōkawa, 2000; Gütlich et al., 2001; Culp et al., 2005; Roy et al., 2008). The archetypical $\mathrm{PB},\left[\mathrm{Fe}_{4}\left\{\mathrm{Fe}(\mathrm{CN})_{6}\right\}_{3}\right] \cdot x \mathrm{H}_{2} \mathrm{O}$, has a cubic network structure in which the Fe atoms lie at the lattice points and the cyanide groups are bridging (Buser et al., 1977). It orders ferromagnetically below $T_{\mathrm{C}}=5.6 \mathrm{~K}$ (Herren et al., 1980). Many methods have been developed over the last 50 years for the synthesis of PB and PBs. In 1960, Pauling and Pauling reported the first "Super-PB" of trisilver cobalt(III) hexacyanide, $\mathrm{Ag}_{3}\left[\mathrm{Co}(\mathrm{CN})_{6}\right]$, from powder X-ray data. The structure contains $\mathrm{NC}-\mathrm{Ag}-\mathrm{CN}$ bridges between two cobalt metal ions to form three interpenetrating frameworks, with the edge of the unit cube having a value of $c a .10 .2$ $\AA$ (Pauling and Pauling, 1960). Much later, Robson and co-workers reported a single crystal structure of the related compound $\operatorname{Rb}\left[\operatorname{Cd}\left\{\operatorname{Ag}(C N)_{2}\right\}_{3}\right]$. The structure contains
three identical, independent and interpenetrating of $\alpha$-Po-related 3-D nets, with an approximately linear $\mathrm{NC}-\mathrm{Ag}-\mathrm{CN}$ connector in place of the CN of the parent of PB . The Cd $\cdots \mathrm{Cd}$ distance of cuboid edge connectors is $24.5 \AA$, whereas, the other three solid diagonals of the cuboid are contracted with the $\mathrm{Cd} \cdots \mathrm{Cd}$ distance of $16.5 \AA$ and remain equivalent to each other (Hoskins et al., 1994). In order to address the challenge and obtain 3-D super PBs, Fischer and co-workers used a planar $\mathrm{Me}_{3} \mathrm{Sn}^{+}$ fragment as spacer to replace each $\mathrm{Ag}(\mathrm{I})$ ion of super PB . The resulting 3-D framework organotin(IV) polymer $\left[\left(\mathrm{Me}_{3} \mathrm{Sn}\right)_{3} \mathrm{Co}(\mathrm{CN})_{6}\right]$ has a $\mathrm{Co} \cdots$ Co separation across the $\mathrm{N}-\mathrm{Sn}-\mathrm{N}$ spacer of ca. $9.5 \AA$ (Behrens et al., 1992). Following these studies, several more 3-D super PB complexes, eg. $\left[\left(\mathrm{Me}_{2} \mathrm{Sn}\right)_{3}\left\{\mathrm{Co}(\mathrm{CN})_{6}\right\}_{2}\right] \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (Siebel et al., 2000), $\left[\left(\mathrm{Me}_{3} \mathrm{Sn}\right)_{3} \mathrm{M}(\mathrm{CN})_{6}\right]$, where $\mathrm{M}=\mathrm{Co}$ and $\mathrm{Ir}(\mathrm{Poll}$ et al., 2001) were also prepared having different $\mathrm{M} \cdots \mathrm{M}$ separations across the spacers.

Many polymeric structures have been reported of "molecular" $\mathrm{CN}^{-}$type structures and clusters containing chelating co-ligands such as $\left[\left\{\mathrm{Ni}^{\mathrm{II}}(\mathrm{bpm})_{2}\right\}_{3}\left\{\mathrm{Fe}^{\mathrm{III}}\right.\right.$ $\left.\left.(\mathrm{CN})_{6}\right\}_{2}\right] \cdot 7 \mathrm{H}_{2} \mathrm{O}, \mathrm{bmp}=\operatorname{bis}(1-$ pyrazolyl)methane (Van Langenberg et al., 1997) and $\left[\mathrm{Ni}^{\mathrm{II}}(\mathrm{tn})_{2}\right]_{3}\left[\mathrm{Fe}^{\mathrm{III}}(\mathrm{CN})_{6}\right]_{2} \cdot \mathrm{X}, \mathrm{tn}=$ diaminopropane, $\mathrm{X}=\mathrm{ClO}_{4}, \mathrm{BF}_{4}, \mathrm{PF}_{6}$ (Ohba et al., 1997). Charged dinitrile of the dca type, $\mathrm{N}(\mathrm{CN})_{2}^{-}$, have been used in studies of $\left[\mathrm{M}\left\{\mathrm{N}(\mathrm{CN})_{2}\right\}_{2}\right]$ compounds that form 3-D networks and display long-range magnetic order in most case, where $\mathrm{M}=\mathrm{Cr}, \mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}$ and Cu (Batten and Murray, 2003).

The polymeric approach has also been used for the construction of Fe (II) SCO compounds (Real et al., 1995; Kahn and Martinez, 1998). This strategy consists of linking together the SCO sites by covalent bridges into extended polymeric structures. In 1999, the first example of a 3-D polymeric complex, $\left[\mathrm{Fe}(\mathrm{btr})_{3}\right]\left(\mathrm{ClO}_{4}\right)_{2}, \mathrm{btr}=$ $\operatorname{tris}\left(4,4^{\prime}\right.$-bis-1,2,4-triazole), exhibiting a cooperative SCO has been reported by Kahn
and co-workers (Garcia et al., 1999). Subsequently, Real et al reported 3-D SCO Hofmann-like networks $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{pz}) \mathrm{M}^{\mathrm{II}}(\mathrm{CN})_{4}\right] \cdot n \mathrm{H}_{2} \mathrm{O}$, where pyz $=$ pyrazine, $\mathrm{M}=\mathrm{Ni}, n=$ 2; Pd, $n=2.5$, and Pt, $n=2.5$, and found that their magnetic and chromatic properties changed abruptly and they displayed thermal- and pressure-induced hysteresis at temperatures close to room temperature (Niel et al., 2001). The assembly of $\left[\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right]$ groups, $\mathrm{Fe}(\mathrm{II})$, and pyrimidine afforded triply interpene-trated, porous 3D SCO polymers of formula $\left[\mathrm{Fe}(\mathrm{pmd})\left(\mathrm{H}_{2} \mathrm{O}\right)\left\{\mathrm{M}^{\mathrm{I}}(\mathrm{CN})_{2}\right\}_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$, where $\mathrm{M}^{\mathrm{I}}=\mathrm{Ag}$ and Au, pmd = pyrimidine (Niel et al., 2003). Murray and Kepert (2004) described 3-D SCO materials incorporating 2-connecting di-pyridyls and these showed very interactive guest dependent effects. Most of the more open framework Fe(II) SCO coordination polymers incorporate N -donating heterocyclic type ligands of the linked di-triazole or di-tetrazole (Grunert et al., 2004; Absmeier et al., 2006). Neutral organonitrile bridged spacer using $\mathrm{NC}-\mathrm{R}-\mathrm{CN}$ ligands are much less well known. One example with $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4}$ has been used in dinuclear Fe (II) SCO compounds (Batten et al., 2004). The anionic dinitrile, $\mathrm{N}(\mathrm{CN})_{2}^{-}$(dca), has also been used as a bridge in dinuclear SCO compounds (Ortega-Villar et al., 2005; Murray, 2008).

An early report by Zuur and co-workers deal with neutral dinitrile ligands and the influence of linking azo groups on complex formation (Zuur et al., 1984). This group synthesized a number of compounds of the type $\left[\mathrm{M}(\mathrm{AIBN})_{3}\right]\left[\mathrm{InCl}_{4}\right]_{2}$ where M is $\mathrm{Fe}, \mathrm{Co}, \mathrm{Ni}$, and Zn , AIBN is a potential bridging, 2-connecting dinitrile, 2,2'azobisisobutyronitrile. They studied their spectral and magnetic properties and concluded that three ligand molecules are used for complete octahedral coordination as evidenced by the optical (d-d) and IR spectra. Interestingly, the iron(II)-complex was reported to exhibit a high spin-low SCO transition with the magnetic moment
dropping from $5.9 \mu_{\mathrm{B}}$ at room temperature to $4.6 \mu_{\mathrm{B}}$ at 70 K . However, there was no crystal structure explored. Therefore, it prompted us in the present work to confirm and elucidate the structure and magnetism using the same AIBN ligand, and a related one, Scheme 1. In this chapter is reported the synthesis, single crystal structural and magnetic and Mössbauer spectral investigation of complexes of formula $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{L})_{3}\right]\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$, where L is either 1, 1 '-azobiscyclopentanecarbonitrile (ACCN) or 2,2'-azobisisobutyronitrile (AIBN), $\mathrm{M}^{\text {III }}=\mathrm{Fe}$ or In. It will be shown that, they have 3D $\alpha$-Po type framework structures. The compounds synthesized were $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$ (6a), $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(\mathbf{6 b}),\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{ACCN})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$ (6d), and $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{ACCN})_{3}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$ (6e). The crystal structure of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN}) \mathrm{H}_{2} \mathrm{O}\right]$ $\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(\mathbf{6 c})$, which was a minor phase separated from the reaction producing $\mathbf{6 b}$, is also briefly described.

1,1'-azobiscyclohexanecarbonitrile (ACCN)

2,2'-azobisisobutyronitrile (AIBN)

Scheme 1 The ligands (left) ACCN and (right) AIBN used for this study. They are capable of binding to two metal ions via the $\mathrm{C} \equiv \mathrm{N}$ nitrogen donors but not via the azo group.

As indicated above, there are a number of polynuclear Fe (II) SCO network structures known using 2-connecting di-triazoles and di-tetrazoles but none are known using dinitriles. Compounds $\mathbf{6 a}$ and $\mathbf{6 b}$ are thus the first example of 3-D Fe(II) SCO containing dinitrile ligands.

### 6.2 Experimental Section

### 6.2.1 Materials and Physical Measurements

$\mathrm{FeCl}_{2}, \mathrm{FeCl}_{3}, \mathrm{InCl}_{3}, \mathrm{ACCN}$, and AIBN were purchased from commercial sources and used without further purification.

Microanalytical measurements ( $\mathrm{C}, \mathrm{H}, \mathrm{N}$ ) were performed by Campbell Microanalytical Laboratory, Chemistry Department, University of Otago, Dunedin, New Zealand. Infrared spectra of Nujol mulls were recorded using a diamond-ATR cell on a Bruker Opus/IR IFS 55 spectrometer in the range of $600-4000 \mathrm{~cm}^{-1}(50$ scans, resolution $\pm 4 \mathrm{~cm}^{-1}$ ). Thermogravimetric analysis (TGA) was performed on a Perkin-Elmer TGA 7 thermogravimetric analyzer in the air with a heating rate of 10 ${ }^{\circ} \mathrm{C} / \mathrm{min}$. Variable-temperature magnetic susceptibility data were obtained by Dr. Boujemaa Moubaraki, School of Chemistry, Monash University, using a Quantum Design MPMS 5 SQUID magnetometer for DC magnetization measurements. Mössbauer measurements were obtained by Assoc. Prof. Dr. John D. Cashion, School of Physics, Monash University. The spectra were measured using a conventional constant acceleration drive with a symmetrical saw-tooth waveform. The source of ${ }^{57} \mathrm{Co}$ in rhodium was maintained at room temperature. Fresh crystalline samples were loaded into a piston type Perspex holder. The holder was placed in a cold-finger type cryostat in good thermal contact with a reservoir containing liquid nitrogen. The
spectra were fitted to Lorentzian lines, with the matching lines of a doublet constrained to have the same intensity and line width. Isomer shifts were calibrated against the spectrum of $\alpha$-iron.

### 6.2.2 Syntheses

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(6 a)$

Method \#1: A single crystal of 6a suitable for X-ray crystallographic analysis was obtained by slow diffusion in which $\mathrm{MeNO}_{2}$ solutions of 14 mL capacity were contained in an H-shaped tube and allowed left in the dark. In a typical experiment, $\mathrm{FeCl}_{2}(62 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{InCl}_{3}(220 \mathrm{mg}, 1 \mathrm{mmol})$ were dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to formed a bright yellow-brown solution and this was pipetted into one side of the H-tube. AIBN ( $250 \mathrm{mg}, 1.5 \mathrm{mmol}$ ) was dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to give a colorless solution and this was pipetted into the other side arm of the H-tube. The Htube was then carefully filled with $\mathrm{MeNO}_{2}$. Upon slow diffusion for three weeks, yellow blocks shaped single crystals of $\mathbf{6 a}$ were formed in the iron-indium-containing side of the H -tube. Yield: $20 \mathrm{mg}, 32 \%$ based on $\mathrm{FeCl}_{2}$.

Method \#2: The route of Zuur et al., (1984) was followed. $\mathrm{FeCl}_{2}$ ( $62 \mathrm{mg}, 0.5$ $\mathrm{mmol}), \mathrm{InCl}_{3}(220 \mathrm{mg}, 1 \mathrm{mmol})$ and AIBN ( $250 \mathrm{mg}, 1.5 \mathrm{mmol}$ ) were dissolved in 15 mL of $\mathrm{MeNO}_{2}$ with vigorous stirring. After 24 hrs of stirring under $\mathrm{N}_{2}$, a white precipitate of $\mathbf{6 a}$ was filtered off and washed with small amount of $\mathrm{MeNO}_{2}$ and diethyl ether subsequently and dried in vacuum over $\mathrm{P}_{2} \mathrm{O}_{5}$. Yield: $50 \mathrm{mg}, 82 \%$ based on $\mathrm{FeCl}_{2}$. The IR spectrum of this sample is similar to that of the sample obtained by the slow diffusion method above. Found (calcd) for $\mathrm{C}_{24} \mathrm{H}_{36} \mathrm{Cl}_{8} \mathrm{FeIn}_{2} \mathrm{~N}_{12}(\mathrm{Mr}=1061.73$ $\mathrm{g} / \mathrm{mol}): \mathrm{C}, 27.11(27.15) ; \mathrm{H}, 3.40(3.42)$, $\mathrm{N}, 15.78(15.83)$. ATR-FTIR ( $v_{\max } /$ $\mathrm{cm}^{-1}$ ): 717w, 856w, 958w, 1178s, 1217s, 1369m, 1388m, 1438w, 1461w, 1599m,

1982w, 2051w, 2166w, 2286m, 2314w, 2944w, 2996m, 3404w. TGA (under air ambient, rate $\left.10{ }^{\circ} \mathrm{C} \mathrm{min}^{-1}\right)-\Delta w\left(122-130^{\circ} \mathrm{C}\right)=45.8 \%$, corresponding to loss of AIBN molecules ( $46.4 \%$ theory). $\mu_{\mathrm{eff}}(300 \mathrm{~K})=5.28 \mu_{\mathrm{B}}$.

## Preparation of $\left[\mathrm{Fe}^{\text {II }}(\mathrm{AIBN})_{3}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(6 \mathrm{~b})$ and $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(6 \mathrm{c})$

Single crystals of $\mathbf{6 b}$ and $\mathbf{6 c}$ were synthesized from the same reaction and were prepared following the procedure described above for $\mathbf{6 a}$, except that $\mathrm{FeCl}_{3}$ was used instead of $\mathrm{FeCl}_{2}$ and without $\mathrm{InCl}_{3}$. Typically, $\mathrm{FeCl}_{3}(81 \mathrm{mg}, 0.5 \mathrm{mmol})$ was dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to formed a yellow-brown solution and this was pipetted into one side of the H-tube. AIBN ( $250 \mathrm{mg}, 1.5 \mathrm{mmol}$ ) was dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to give a colorless solution and this was pipetted into the other side arm of the H -tube. The H-tube was then carefully filled with $\mathrm{MeNO}_{2}$. Upon slow diffusion for two weeks, yellow block-shaped (6b) and pale yellow plate (6c) single crystals were formed in the iron-containing side of the H-tube. Yield: $21 \mathrm{mg}, 27 \%$ ( $\mathbf{6 b}$ ) and 4 mg $5 \%(\mathbf{6 c})$ based on $\mathrm{FeCl}_{3}$. Anal. Found (calcd) for $\mathbf{6 b}, \mathrm{C}_{24} \mathrm{H}_{36} \mathrm{Cl}_{8} \mathrm{Fe}_{3} \mathrm{~N}_{12}(M r=943.79$ $\mathrm{g} / \mathrm{mol}): \mathrm{C}, 30.52(30.54) ; \mathrm{H}, 3.82(3.85), \mathrm{N}, 17.78(17.81)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right)$ : 713m, 853w, 951w, 1176s, 1216s, 1367m, 1385m, 1440m, 1464m, 1609m, 1642w, 1982w, 2051w, 2165w, 2242w, 2282s, 2945w, 2998m, 3458br. $\mu_{\text {eff }}(250$ K $)=9.90 \mu_{\mathrm{B}}$.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathbf{A C C N})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(\mathbf{6 d})$

Method \#1: Single crystals of $\mathbf{6 c}$ were prepared following the procedure described above for $\mathbf{6 a}$, except that ACCN was used instead of AIBN. In a typical experiment procedure, $\mathrm{FeCl}_{2}(62 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathrm{InCl}_{3}(220 \mathrm{mg}, 1 \mathrm{mmol})$ were dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to formed a bright yellow-brown solution and this was
pipetted into one side of the H-tube. ACCN ( $360 \mathrm{mg}, 1.5 \mathrm{mmol}$ ) was dissolved in 3 mL of $\mathrm{MeNO}_{2}$ to give a colorless solution and this was pipetted into the other side arm of the H -tube. The H -tube was then carefully filled with $\mathrm{MeNO}_{2}$. Upon slow diffusion for three weeks, yellow block shaped single crystals of $\mathbf{6 c}$ were formed in the iron-indium-containing side of the H -tube. Yield: $33 \mathrm{mg}, 54 \%$ based on $\mathrm{FeCl}_{2}$.

Method \#2: The route of Zuur et al., (1984) was followed. $\mathrm{FeCl}_{2}$ ( $62 \mathrm{mg}, 0.5$ $\mathrm{mmol}), \mathrm{InCl}_{3}(220 \mathrm{mg}, 1 \mathrm{mmol})$ and $\mathrm{ACCN}(360 \mathrm{mg}, 1.5 \mathrm{mmol})$ were dissolved in 15 mL of $\mathrm{MeNO}_{2}$ and vigorous stirring for 24 hrs . The resulting white precipitate was filtered off and washed with small amount of $\mathrm{MeNO}_{2}$ and diethyl ether subsequently and dried in vacuum over $\mathrm{P}_{2} \mathrm{O}_{5}$. Yield: $55 \mathrm{mg}, 90 \%$ based on $\mathrm{FeCl}_{2}$. The IR spectrum of this sample is similar to that of the sample obtained by the slow diffusion method, above. Anal. Found (calcd) for $\mathrm{C}_{42} \mathrm{H}_{60} \mathrm{Cl}_{8} \mathrm{FeIn}_{2} \mathrm{~N}_{12}(\mathrm{Mr}=1184.17 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 27.14$ (27.15); H, 3.40(3.42), N, 15.82(15.83). ATR-IR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 851 \mathrm{w}, 906 \mathrm{~m}, ~ 943 \mathrm{~m}$, 1071w, 1163w, 1256w, 1285w, 1442s, 1556w, 2116w, 2276w, 2862m, 2936w, $2949 \mathrm{~s}, 3466 \mathrm{w} . \mu_{\mathrm{eff}}(300 \mathrm{~K})=5.26 \mu_{\mathrm{B}}$.

## Preparation of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{ACCN})_{3}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(6 e)$

Single crystals of $\mathbf{6 d}$ were prepared following the procedure described above for $\mathbf{6 b}$, except that ACCN was used. Pale yellow block-shaped single crystals of $\mathbf{6 d}$ were formed in the iron-containing side of the H-tube. Yield: $35 \mathrm{mg}, 43 \%$ based on $\mathrm{FeCl}_{3}$. Anal. Found (calcd) for $\mathrm{C}_{42} \mathrm{H}_{60} \mathrm{Cl}_{8} \mathrm{Fe}_{3} \mathrm{~N}_{12}(M r=1184.17 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 42.54$ (42.60); H, $5.09(5.11), \mathrm{N}, 14.15(14.19)$. ATR-FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 854 \mathrm{w}, 957 \mathrm{w}, 1173 \mathrm{~s}$, 1223s, $1369 \mathrm{~m}, 1388 \mathrm{~m}, 1438 \mathrm{w}, 1461 \mathrm{w}, 1602 \mathrm{~m}, 1991 \mathrm{w}, 2063 \mathrm{w}, 2177 \mathrm{w}, 2239 \mathrm{~m}$, $2301 \mathrm{w}, 2941 \mathrm{w}, 3002 \mathrm{~m}, 3414 \mathrm{w} \cdot \mu_{\mathrm{eff}}(300 \mathrm{~K})=9.59 \mu_{\mathrm{B}}$.

### 6.2.3 X-Ray Crystallographic Study

Single crystals of $\mathbf{6 a - 6 e}$ were mounted on MiTeGen MicroMounts fibers in a small amount of oil prior to measurements made by Dr. Suzanne M. Neville and Dr. Craig Forsyth, Monash University. Reflection intensities were collected on a Bruker X8 APEX CCD diffractometer using Mo $K \alpha(\lambda=0.71073 \AA)$ radiation and equipped with an Oxford Instruments nitrogen gas Cryostream. Empirical absorption corrections were applied to all data using SADABS (Blessing, 1995). The structures were solved using SHELXS and refined on $F^{2}$ using SHELXL-97 (Sheldrick, 1997) with X-SEED (Barbour, 2001) as a graphics interface.

In the final cycles of refinement, all atoms except hydrogen atoms were refined anisotropically. Hydrogen atoms were placed in geometrically idealized positions and constrained to ride on their parent atoms, with $\mathrm{C}-\mathrm{H}=0.99 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ for CH groups, and with $\mathrm{C}-\mathrm{H}=0.97 \AA$ and $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{C})$ for methyl groups.

For $\mathbf{6 c}$, hydrogen atoms attached to oxygen atoms of the water molecules were located in a difference Fourier map and refined as riding in their as-found positions with a DFIX restraint of $\mathrm{O}-\mathrm{H}$ distance at $0.90 \AA$, with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{O})$. For $\mathbf{6 a}$ was refined as a racemic twin using the TWIN and BASF commands in SHELXL-97 (Sheldrick, 1997). The twin law was ( $010 / 100 / 00-1$ ) and the final value of the BASF parameter was $0.471(17)$ for 103 K and $0.029(2)$ for 233 K .

Crystal data and details of the data collection and structure refinement for compounds $\mathbf{6 a - 6 c}$ and $\mathbf{6 c - 6 d}$ are summarized in Tables 6.1 and 6.2, respectively. Selected interatomic bond lengths and angles for compounds $\mathbf{6 a}-\mathbf{6 b}, \mathbf{6 c}$, and $\mathbf{6 d - 6 e}$ are given in Tables 6.3, 6.4, and 6.6, respectively. The hydrogen bonds geometries for

6c are given in Table 6.5. The bond lengths and angles and other crystallographic data are given as supplementary material in the CIF which can be found on the attached CD-ROM.

### 6.3 Results and Discussion

### 6.3.1 Syntheses and Characterizations

The iron(II) compounds are air- and moisture-sensitive solids. To isolate compounds $\mathbf{6 a}, \mathbf{6} \mathbf{b}, \mathbf{6 d}$ and $\mathbf{6 e}$ reproducibly, from $\mathrm{MeNO}_{2}$ solutions, it is necessary to remove all traces of air and moisture. The experiments were therefore performed under $\mathrm{N}_{2}$. During the synthesis of $\mathbf{6 b}$, if traces of air moisture are present, the minor product of the aqua complex of $\mathbf{6 c}$ is obtained in $c a .5 \%$ yields.
$\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{L})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$, where L is $\operatorname{AIBN}(6 a)$ and $\operatorname{ACCN}(\mathbf{6 d})$, were obtained as pale-yellow block shaped crystals by the reactions of anhydrous $\mathrm{FeCl}_{2}, \mathrm{InCl}_{3}$, and L mixed in $\mathrm{MeNO}_{2}$, in a 1:2:3 molar ratio. An H-shaped tube was employed and the solution left in the dark at room temperature. When 3 equivalents of $L$ were slowly diffused into 1 equivalent of anhydrous $\mathrm{FeCl}_{3}$ in $\mathrm{MeNO}_{2}$, yellow block-shaped
crystals of $\mathbf{6 b}$ ( L is AIBN) and $\mathbf{6 e}$ ( L is ACCN) were also isolated. Curiously, the balanced chemical equations representing the syntheses of the crystalline products $\mathbf{6} \mathbf{b}$ and $\mathbf{6 e}$ do not correspond to the actual stoichiometric ratio of reactants used, when $3 \mathrm{FeCl}_{3}+9 \mathrm{~L}$ is considered since $\mathrm{Fe}(\mathrm{II})$ is reduced, in part, to $\mathrm{Fe}(\mathrm{II})$. The dinitrile groups on the ligands may function as reducing agents. The syntheses involved equations 1 and 2 , respectively.

$$
\begin{align*}
& \mathrm{FeCl}_{2}+2 \mathrm{InCl}_{3}+3 \mathrm{~L} \xrightarrow[\text { RT }]{\mathrm{MeNO}_{2}} \xrightarrow[\substack{\text { 6a, } \mathbf{d d}}]{\left[\mathrm { Fe } ( \mathrm { L } ) _ { 3 } \left[\left[\mathrm{InCl}_{4}\right]_{2}\right.\right.}  \tag{1}\\
& 3 \mathrm{FeCl}_{3}+9 \mathrm{~L} \quad \xrightarrow[\text { RT }]{\mathrm{MeNO}_{2}}\left[\mathrm{Fe}(\mathrm{~L})_{3}\right]\left[\mathrm{FeCl}_{4}\right]_{2}  \tag{2}\\
& \text { 6b, 6e }
\end{align*}
$$

Single crystals of all compounds are unstable and sensitive to oxidation or hydrolysis, when they are taken from the mother liquor and exposed to moist air. Yellowish powder compounds are thus formed. A white powder sample of $\mathbf{6 a}$ was prepared according to the literature (Zuur et al., 1981), and was phase pure as judged by microscopic visual examination and microelemental analysis. The IR spectra of the compounds provide spectral evidence for the occurrence of bridging organonitrile ligands. The CN stretching band is shifted to higher wave numbers compare to those for the free AIBN ( $2243 \mathrm{~m} \mathrm{~cm}^{-1}$ ) or ACCN $\left(2237 \mathrm{~m} \mathrm{~cm}^{-1}\right)$ ligands. The bridging coordinated organonitrile group frequency is now higher when a cyanide group is bridged to a second metal: $2286 \mathrm{~m}(\mathbf{6 a}), 2274 \mathrm{~m}(\mathbf{6 b}), 2241 \mathrm{~m}(6 \mathbf{d})$, and $2239 \mathrm{~m} \mathrm{~cm}^{-1}$ (6e). TGA showed that 3-D nets of compound 6a are thermally stable up to $c a .120$ ${ }^{\circ} \mathrm{C}$ after lose the AIBN ligands.

### 6.3.2 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathbf{A I B N})_{3}\right]\left[\mathrm{MII}^{\mathrm{II}} \mathrm{Cl}_{4}\right]_{2}, \mathrm{M}^{\mathrm{III}}=\mathrm{In}(6 \mathrm{a}), \mathrm{Fe}(6 \mathrm{~b})$

The X-ray single crystal structure analysis was performed at 103 and 223(2) K using the same crystal. At both temperatures the compounds have isomorphous structures of formula $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$, where $\mathrm{M}^{\mathrm{III}}=\mathrm{In}(\mathbf{6 a})$ and $\mathrm{Fe}(\mathbf{6 b})$, and crystallize in the trigonal space group $R \overline{3}$ (No. 148). There is no crystallographic phase transition as the temperature is lowered. The asymmetric unit with atomic numbering is shown in Figure 6.1 ( $\mathbf{6 a}$ uses the same numbering as in $\mathbf{6 b}$ ). It contains two crystallographically independent Fe atoms, half of two $\left[\mathrm{MCl}_{4}\right]$ anions, and one AIBN molecule. All metal ions lie on special position of the three fold inversion axis and have an inversion center. The midpoint of the AIBN ligands coincides with an inversion center. At 233 K , all the $\mathrm{Fe}(\mathrm{II})$ ions are in the HS state. At 103 K , however, the Fe 1 site is now characteristic of the Fe (II) ion in the LS state, while the Fe 2 site remains characteristic of Fe (II) ion in the HS state.

HS-HS complex structure ( $\boldsymbol{T}=\mathbf{2 3 3} \mathbf{K}$ ). Each Fe atom is coordinated by six nitrogen atoms from each of six AIBN ligands. At 233 K , the $\mathrm{Fe}-\mathrm{N}$ bond lengths in the $\mathrm{FeN}_{6}$ coordination core of $\mathbf{6 a}(2.139(6) \AA$ for Fe 1 and $2.175(6) \AA$ for Fe 2$)$ correspond to the values found for $\mathbf{6 b}$ (2.133(3) $\AA$ for Fe 1 and 2.171(3) $\AA$ for Fe 2$)$. These values are typical of a HS Fe(II) complex with six similar N -donor atoms as observed for the 3-D polymeric SCO of $\left[\mathrm{Fe}(\mathrm{btr})_{3}\right]\left[\mathrm{ClO}_{4}\right]_{2}$, where $\mathrm{btr}=\operatorname{tris}\left(4,4^{\prime}\right.$-bis-1,2,4-triazole) (Garcia et al., 1999) and $\left[\mathrm{Fe}(\mathrm{pbtz})_{3}\right]\left[\mathrm{ClO}_{4}\right]_{2}$, where $\mathrm{pbtz}=1,3-$ di(tetrazol-2-yl)propane (Bronisz, 2007).

Figure 6.1 View showing asymmetric unit with the atom numbering in 6a. Thermal ellipsoids are drawn at the $50 \%$ probability level at 103 K . The hydrogen atoms are omitted for clarity. Compound $\mathbf{6 b}$ is isostructural.

The Fe 2 octahedron ( $\mathrm{N} 4-\mathrm{Fe} 2-\mathrm{N} 4^{\prime}=87.5(2)^{-92.5(2)^{\circ}}$ for $\mathbf{6 a}$ and $87.1(1)^{-}$ $92.8(1)^{\circ}$ for $\mathbf{6 b}$ ) is slightly more distorted from the ideal geometry $\left(90^{\circ}\right)$ than that found in the Fel octahedron $\left(\mathrm{N} 1-\mathrm{Fe} 1-\mathrm{N} 1^{\prime}=89.6(2)-90.4(2)^{\circ}\right.$ for $\mathbf{6 a}$, and 89.2(1)$90.7(1)^{\circ}$ for $\mathbf{6 b}$ ). However, this distortion remains limited, as shown by the values (close to 180 or $90^{\circ}$ ) of the $\mathrm{N}-\mathrm{Fe}-\mathrm{N}$ angles (Table 6.3). The octahedral angular distortion around the Fe 2 centre in $\mathbf{6 a}$ and $\mathbf{6 b}$, defined as $\Sigma$, the sum of the deviations from $90^{\circ}$ (the trigonal distortion angle $=0$ for a perfect octahedron) of the twelve $[\mathrm{N}-\mathrm{Fe}-\mathrm{N}]$ angles $\left(\Sigma=30.0^{\circ}\right.$ for $\mathbf{6 a}$, and $33.8^{\circ}$ for $\mathbf{6 b}$ ), is large compared with the Fe 1 centres $\left(\Sigma=4.8^{\circ}\right.$ for $\mathbf{6 a}$, and $8.4^{\circ}$ for $\left.\mathbf{6 b}\right)$. The $\mathrm{Fe}-\mathrm{N}-\mathrm{C}$ bond angles range
respectively from $170.7(6)-174.4(5)^{\circ}$ and $170.5(2)-172.6(2)^{\circ}$ for $\mathbf{6 a}$ and $\mathbf{6 b}$ and are somewhat bent from strict linearity. This is one factor accounting for the distortion from ideal octahedral geometry of the Fe (II) centre in the present compounds.

The bridging AIBN ligands for both compounds have an $S$-shaped conformation. All atoms except those of the methyl groups are nearly planar. For the plane consists of the best plane of eight atoms (N1, C1, C2, N2, N3, C3, C4, N4) referred to the orthogonalized axial system, the r. m. s. deviation of fitted atoms is 0.019 and $0.020 \AA$ with the largest deviation being $0.044(6)$ and $0.0043(3)$ at N 2 (which is in the double bond) for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively. The atoms of the two methyl groups are not of course in the plane. The conformation of the AIBN ligand can also described by the torsion angles: $\mathrm{N} 1-\mathrm{C} 1-\mathrm{C} 2-\mathrm{N} 2=169.2(1)^{\circ}$ for $\mathbf{6 a}$ and $166.3(3)^{\circ}$ for $\mathbf{6 b}, \mathrm{N} 4-\mathrm{C} 4-\mathrm{C} 3-\mathrm{N} 3=-142.1(2)^{\circ}$ for $\mathbf{6 a}$ and $-130.01(1)^{\circ}$ for $\mathbf{6 b}$. The $\mathrm{N} 1 \cdots \mathrm{~N} 4$ separations are $6.609(7)$ and $6.601(3) \AA$ for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively. These values are slightly shorter than those of $6.67 \AA$ for the free AIBN ligands (Argay and Sasvári, 1971). The $\mathrm{Fe} 1 \cdots \mathrm{Fe} 2$ separations across the AIBN ligands are 10.5398(7) and 10.4408(2) $\AA$ for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively.

HS-LS complex structure ( $\boldsymbol{T}=\mathbf{1 0 3} \mathbf{K}$ ). On cooling to 103 K , the $\mathrm{Fe}-\mathrm{N}$ bond lengths are markedly temperature dependent as depicted in Figure 6.2 and listed in Table 6.3. The Fe1 -N 1 bond lengths $(\mathbf{6 a}=2.000(6) \AA, \mathbf{6 b}=1.945(2) \AA)$ are shorter than those for the $\mathrm{Fe} 2-\mathrm{N} 4$ bonds $(\mathbf{6 a}=2.177(6) \AA, \mathbf{6 b}=2.176(2) \AA)$. The $\mathrm{Fe}-\mathrm{N}$ bond lengths exhibit significantly different values within experimental error $(3 \sigma)$ as large as $c a .0 .1-0.2 \AA(\Delta d[\mathrm{Fe}-\mathrm{N}]=0.1$ for $\mathbf{6 a}$ and $0.2 \AA$ for $\mathbf{6 b})$. HS

LS-HS, Red
$T=103 \mathrm{~K}$, trigonal, $R \mathbf{3}$

Figure 6.2 Comparison of $\mathrm{Fe}-\mathrm{N}$ bond lengths in $\mathbf{6 a}$ and $\mathbf{6 b}$ at 103 and 233 K .
octahedral complexes of transition metal ions, i.e. $\mathrm{d}^{6} \mathrm{Fe}(\mathrm{II})$, are expected to display larger radii, and hence longer metal-ligand bonds than their LS counterparts upon moving from HS, $S=2$ to LS, $S=0$ (Gütlich et al., 1994). Therefore, the long $\mathrm{Fe}-\mathrm{N}$ bonds in $\mathbf{6 a}$ and $\mathbf{6 b}$ indicate the presence of a HS iron(II) ion, whereas, the short $\mathrm{Fe}-\mathrm{N}$ bonds point to a LS configuration of the iron(II) ion. This shortening of the $\mathrm{Fe}-\mathrm{N}$ bond lengths after lowering temperatures is a characteristic feature of the $\mathrm{HS} \rightarrow$ LS transition which was similar to that observed in other Fe(II) SCO complexes: $\left[\mathrm{Fe}(\mathrm{btzb})_{3}\right]\left[\mathrm{PF}_{6}\right]_{2}$, where btzb $=1,4$-bis(tetrazol-1-yl)butane-N4,N4' (Grunert et al., 2004), $\left[\mathrm{Fe}(n \text { ditz })_{3}\right]\left[\mathrm{ClO}_{4}\right]_{2}$, where $n=4-9$, ditz $=\operatorname{bis}($ tetrazol-1-yl)alkane-N4,N4' $(A b s m e i e r ~ e t ~ a l ., ~ 2006), ~\left[F e(N C S)_{2}(b p b d)_{2}\right] \cdot\{$ acetone $\}, \operatorname{bpbd}=2,3$-bis $(4 '-$ pyridyl $)-2,3-$ butanediol (Neville et al., 2007), and $\left[\mathrm{Fe}(\mathrm{NCSe})_{2}(\mathrm{cddt})\right] \cdot 2(\mathrm{MeOH})$ and $\left[\mathrm{Fe}(\mathrm{NCS})_{2}\right.$ (cddt)] $2(\mathrm{MeOH})$, where $\mathrm{cddt}=2$-chloro-4,6-bis(di-pyrid-2-ylamino)-1,3,5-triazine (Neville et al., 2007). The Fe1-N1 distances are decreased by 6.8 and $9.8 \%$ on going from the HS $(233 \mathrm{~K})$ to the LS $(103 \mathrm{~K})$ state for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively.

In the 103 K structure, the $\mathrm{N} 1-\mathrm{Fe} 1-\mathrm{N} 1^{\prime}$ bond angles for the LS form vary from $89.2(2)-90.8(2)^{\circ}$ and $89.1(1)-90.9(1)^{\circ}$, and are slightly different for the $\mathrm{N} 4-\mathrm{Fe} 2-\mathrm{N} 4^{\prime}$ angles in the HS species that adopt values of $87.3(2)-92.7(2)^{\circ}$ and 87.1(1)-92.9(1) ${ }^{\circ}$ for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively. Indeed, the decreasing of temperature shows a significant increasing of deformation of the octahedral geometry about the Fe centre as defined by $\Sigma$, the sum of the deviations from $90^{\circ}$ from twelve $[\mathrm{N}-\mathrm{Fe}-\mathrm{N}]$ angles. As depicted in Figure 6.3, the $\mathrm{Fe} 1 \mathrm{~N}_{6}$ chromophore in the LS state shows a significantly greater distortion of the coordination octahedron and is more

Figure 6.3 Schematic representation for comparison of distorted octahedral geometry around $\mathrm{Fe}(\mathrm{II})$ centres in (a) 6a and (b) 6b at 103 (red) and 233 K (yellow).
compressed in comparison to the $\mathrm{Fe} 2 \mathrm{~N}_{6}$ core in the HS species following the $\mathrm{HS} \rightarrow$ LS transition: $\mathrm{Fe} 1: \Sigma=4.8^{\circ}$ at $233 \mathrm{~K} \rightarrow 9.6^{\circ}$ at 103 K for $\mathbf{6 a} ; \Sigma=8.4^{\circ}$ at $233 \mathrm{~K} \rightarrow$ $10.8^{\circ}$ at 103 K for $\mathbf{6 b} ; \mathrm{Fe} 2: \Sigma=30.0^{\circ}$ at $233 \mathrm{~K} \rightarrow 32.4^{\circ}$ at 103 K for $\mathbf{6 a}, 33.8^{\circ}$ at 233 $\mathrm{K} \rightarrow 34.8^{\circ}$ at 103 K for $\mathbf{6 b}$. The slight distortion observed in the present compounds is not unusual for Fe (II) SCO complexes, with similar behaviour observed for other 3D polymeric compounds (Garcia et al., 1999; Bronisz, 2007).

The AIBN bridging ligands show small changes in bond lengths with temperature as shown in Figure 6.4. The main structural modification of the AIBN molecule between 233 and 103 K concerns the coordination sphere of the Fe 1 site and torsion angle changes in AIBN. The $\mathrm{N} 1-\mathrm{C} 1-\mathrm{C} 2-\mathrm{N} 2$ torsion angle is reduced from $169.2(1)^{\circ}$ at 233 K to $151.7(5)^{\circ}$ at 103 K for $\mathbf{6 a}$, but is increased form $166.3(3)^{\circ}$ at 233 K to $171.5(1)^{\circ}$ at 103 K for $\mathbf{6 b}$. Furthermore, the torsion of $\mathrm{N} 4-\mathrm{C} 4-\mathrm{C} 3-\mathrm{N} 3$ is reduced form $-142.2(1)^{\circ}$ at 233 K to $-117.1(2)^{\circ}$ at 103 K for $\mathbf{6 a}$, and is weakly reduced form $-130.1(1)^{\circ}$ at 233 K to $-128.4(2)^{\circ}$ at 103 K for $\mathbf{6 b}$. R. m. s. deviation of fitted atoms is 0.023 and $0.024 \AA$ with the largest deviation being $-0.036(5)$ and $-0.043(1) \AA$ at C 2 for $\mathbf{6 a}$ and $\mathbf{6 b}$, respectively. The largest deviation of atoms at 103 K is now C 2 (at N 2 , at 233 K ). These values indicate that the AIBN molecule reorientates when cooling temperature. The temperature dependence can also be demonstrated by the intramolecular $\mathrm{N} 1 \cdots \mathrm{~N} 4$ separation, which increases by $0.8 \%$ from $6.609(7)$ and $6.601(3) \AA$ at 233 K to $6.666(8)$ and $6.658(2) \AA$ at 103 K for $\mathbf{6 a}$ and 6b, respectively. The $\mathrm{Fe} 1 \cdots \mathrm{Fe} 2$ separations across the AIBN ligands in 6a decreases by $1 \%$ from $10.5398(7) \AA$ at 233 K to $10.4375(3) \AA$ at 103 K , whereas in $\mathbf{6 b}$, it decreases by $1.2 \%$ from $10.4408(2) \AA$ at 233 K to $10.3110(1) \AA$ at 103 K .

Figure 6.4 Views of AIBN ligands in (a) 6a and (b) $\mathbf{6 b}$ at 103 (red) and 233 K (yellow).

Of greater significance is the comparison between the unit cell parameters at the two collection temperatures. The cell volume of the unit cell decreases from 7018.1(12) and $6823.8(4) \AA^{3}$ at 233 K to $6817.9(5)$ and $6574.3(2) \AA^{3}$ at 103 K for $\mathbf{6 a}$ $(\Delta V=3 \%)$ and $\mathbf{6 b}(\Delta V=3.8 \%)$, respectively. The largest change in cell dimensions was for the $c$ axis ( $\Delta c=1.4 \%$ for $\mathbf{6 a}, 1.7 \%$ for $\mathbf{6 b}$ ). The changes in the $a$ and $b$ axes are considerably smaller ( $\Delta a / b=0.7 \%$ for $\mathbf{6 a}, 0.9 \%$ for $\mathbf{6 b}$ ). The characteristic feature of $\mathbf{6 a}$ and $\mathbf{6 b}$ is the thermochromic effect observed in which the HS $\rightarrow$ LS transition is accompanied by a concomitant change from yellow (233 K) to red (103 K). In summary, between the $\mathrm{FeN}_{6}$ chromophores in compounds $\mathbf{6 a}$ and $\mathbf{6 b}$ show that, the Fe 2 core at 103 K does not reveal any significant differences to that at 233 K , whereas
the Fel core undergoes the thermally induced SCO transition between the two temperatures. We see later in the magnetism description this transition occurs between 100 and 150 K for $\mathbf{6 a}$ and $100-200 \mathrm{~K}$ for $\mathbf{6 b}$.

In addition, the geometry of the $\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]$ counter anion in all compounds is distorted tetrahedral. The basic trends in the $\mathrm{M}-\mathrm{Cl}$ bond lengths in $\mathbf{6 a}$ and $\mathbf{6 b}$ at selected temperatures are consistent with the trend in the ionic radii between Fe and In in which the $\mathrm{M}-\mathrm{Cl}$ bond lengths decrease with decrease in the ionic radii of the central metal ions. As expected, the bond lengths of $\mathrm{Fe}^{\text {III }}-\mathrm{Cl}[2.170(7)-2.184(8) \AA$ at 103 K and $2.142(3)-2.170(2) \AA$ at 233 K ] are shorter than those of the $\mathrm{In}^{\mathrm{III}}-\mathrm{Cl}$ bonds [2.298(3)-2.317(4) $\AA$ at 103 K and 2.294(3)-2.308(5) $\AA$ at 233 K$]$. The bond lengths and angles around the anions metal centre at the collected temperatures are typical and comparable to those observed in other four-coordinated $\mathrm{Fe}(\mathrm{III})$ or $\mathrm{In}(\mathrm{III})$ complexes: $2.15-2.31 \AA$ for $\left(\mathrm{SbzSbz}_{2}\left[\mathrm{FeCl}_{4}\right] \mathrm{Cl}\right.$, where $\mathrm{SbzSbz}=3,5$-diphenyl-1,2dithiolium (Mason, et al., 1974), and 2.30-2.36 $\AA$ for $\left(\mathrm{Et}_{4} \mathrm{~N}\right)\left[\mathrm{InCl}_{4}\right]$ (Trotter, et al., 1969).

The extended structure consists of a 3-D cationic host framework of $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]^{2+}$ which is charged balance by two "guest" $\left[\mathrm{MCl}_{4}\right]^{-}$anions. The $\mathrm{Fe}(\mathrm{II})$ centres are six-connected and each Fe (II) atom connects to six other Fe (II) atoms through the nitrile nitrogens of the AIBN ligands to give a 3-D $\alpha$-Po like network (Batten and Robson, 1998), as shown in Figure 6.5. This topology is identical to those found in other 3-D $\alpha$-Po-related nets, eg. three interpenetrating framework structures in the "Super-Prussian-Blue" of $\left[\mathrm{Ag}_{3} \mathrm{Co}(\mathrm{CN})_{6}\right]$ (Pauling and Pauling, 1968),

Figure 6.5 (a) Views of the 3-D net in the structure of $\mathbf{6 a}$ at 103 K . Methyl groups and counter anions are omitted for clarity. (b) Schematic presentation of the $\alpha$-Po related net in 6a. Counter anions and AIBN molecules are represented as space-filling model and yellow solid lines, respectively. Compound $\mathbf{6 b}$ is isostructural.
$\operatorname{Rb}\left[\mathrm{Cd}\left\{\mathrm{Ag}(\mathrm{CN})_{2}\right\}_{3}\right]$ (Hoskins et al., 1994), $\left[\left(\mathrm{Me}_{3} \mathrm{Sn}\right)_{3} \mathrm{Rh}(\mathrm{SCN})_{6}\right]$ (Siebel and Fischer, 1997), and two interpenetrating nets of $\left[M(d c a)_{2}\left(4,4^{\prime}-\right.\right.$ bipy $\left.)\right]$, where $M=F e, C o$, and Ni (Jensen et al., 2002). Within each of the rhombohedral channels are two independent $\left[\mathrm{MCl}_{4}\right]$ counter anions. These ions sterically prevent interpenetration of the coordination networks in a similar way to that of $\left[\mathrm{CoCp}_{2}\right]^{+}$guest cations ions in a 3-D non-interpenetrating open-framework of $\left(\mathrm{CoCp}_{2}\right)\left[\mathrm{Fe}\left(\mu-\mathrm{CNSnMe}_{3} \mathrm{NC}\right)_{3}\right]$ (Schwarz et al., 1995).

A surprising aspect of the structures in $\mathbf{6 a}$ and $\mathbf{6 b}$ is the absence of significant intermolecular hydrogen bonds. There are no intermolecular $\mathrm{C} \cdots \mathrm{Cl}$ contacts of less than $3.45 \AA$ in lengths (Bondi, 1964). The shortest intermolecular $\mathrm{C} \cdots \mathrm{Cl}$ contact has $\mathrm{H}^{\cdots} \mathrm{Cl}$ and $\mathrm{C} \cdots \mathrm{Cl}$ distances of 2.90 and $3.463(12) \AA$, respectively, both too long to be regarded as a significant $\mathrm{C}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bond. The decreasing of the temperature does not involve any differences in the structures of the polymeric network. Therefore, only electrostatic forces and van der Waals interactions appear to contribute to the stabilization of the structures in $\mathbf{6 a}$ and $\mathbf{6 b}$.

### 6.3.3 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN}) \mathrm{H}_{2} \mathrm{O}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(6 \mathrm{c})$

A few yellow plate crystals of $\mathbf{6 c}$ were obtained as a minor product, and were separated by eye from 6b. The X-ray single crystal structure analysis was only determined at 123 K . The compound crystallizes in the monoclinic space group $P 2_{1} / n$ (No. 14). The asymmetric unit comprises one Fe atom on a special position and one AIBN ligand, one coordinated water, and one $\mathrm{FeCl}_{4}$ counter anions in general position, Figure 6.6. The crystal structure of $\mathbf{6 c}$ is made up of the packing of 2-D $(4,4)$ topology polymeric $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN}) \mathrm{H}_{2} \mathrm{O}\right]^{2+}$ cations and $\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-}$anions perpendicular to the crystallographic $b$ axis.

Figure 6.6 View showing the asymmetric unit with the atom numbering in $\mathbf{6 c}$. Thermal ellipsoids are drawn at the $50 \%$ probability level at 123 K . The hydrogen atoms are omitted for clarity. Symmetry codes:

The Fe(II) ion is coordinated by four AIBN nitrogen ligands in the equatorial plane while two water molecules occupy the axial positions, forming a somewhat distorted $\mathrm{FeN}_{4} \mathrm{O}_{2}$ octahedral geometry. The $\mathrm{Fe}-\mathrm{N}$ bond lengths of 2.144(1) [Fe1-N1] and 2.171(1) $\AA\left[\mathrm{Fe} 1-\mathrm{N} 4^{\mathrm{i}}\right.$; (i) $\left.=x-1 / 2,1 / 2-y, z-1 / 2\right]$ are not significantly different within experimental error $(3 \sigma)$ and are comparable to those $\mathrm{Fe}-\mathrm{N}$ bond lengths for the HS species in $\mathbf{6}$ a and $\mathbf{6 b}$. The Fe1-O1 bond length of $2.083(1) \AA$ is well within the sum of the $\mathrm{Fe} / \mathrm{O}$ van der Waals radii of $3.59 \AA$ (Bondi, 1964). The values of the $\mathrm{N}-\mathrm{Fe} 1-\mathrm{N}$ and $\mathrm{N}-\mathrm{Fe} 1-\mathrm{O}$ angles between adjacent atoms are in the range $85.5(1)-94.4(1)^{\circ}$. This shows a strong deviation from the ideal octahedral geometry caused by the coordination of four AIBN ligands and two coordinated water
molecules. The deformation of the octahedral geometry as defined by $\Sigma$, the sum of the deviations from $90^{\circ}$ from four $[\mathrm{N}-\mathrm{Fe}-\mathrm{N}]$ angles and eight $[\mathrm{N}-\mathrm{Fe}-\mathrm{O}]$ is $23.7^{\circ}$.

Figure 6.7 View of 2-D $(4,4)$ sheets in $\mathbf{6 c}$ along the $b$ axis.

As shown in Figure 6.7, viewed perpendicular to the crystallographic $b$ axis, the bridging AIBN ligands in $\mathbf{6 c}$ have again an $S$ shaped conformation, with a N1 $\cdots \mathrm{N} 4$ separation of $6.544(1) \AA$, and then link the Fe(II) ions into a 2-D sheet topology. The cavities in the sheet exhibit rhombohedral grids with a Fe to Fe dimension of $10.3521(2) \times 10.3521(2) \AA$ (the $\mathrm{Fe} \cdots \mathrm{Fe}$ separation across the AIBN ligand) which is somewhat shorter than those of $\mathbf{6 a}$ and $\mathbf{6 b}$. The $\mathrm{Fe} \cdots \mathrm{Fe}$ distances across the windows
are $12.9995(3)$ and $16.1444(4) \AA$. The sheets pack on each other with an interlayer separation of $11.1659(2) \AA(\mathrm{Fe} \cdots \mathrm{Fe})$.

The coordination geometry around the Fe (III) centre of the $\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}$ counter anions is a distorted tetrahedron. The bond lengths and angles around the Fe (III) ions are typical and comparable to those observed in $\mathbf{6 b}$. These counter anions are located between the sheets as shown in Figure 6.8. The 2-D sheet associates into a 3-D structure via $\mathrm{O} \cdots \mathrm{Cl}$ bonds formed between the apical coordination water molecules and Cl atoms of the counter anions (Table 6.5), aligned along the crystallographic $b$ axis.

Figure 6.8 View slightly offset from the $b$ axis showing the 2-D layered structure in 6c. Inclusion of $\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}$ is represented by the space filling models. Hydrogen atoms are omitted for clarity.

### 6.3.4 Structural Description of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathbf{A C C N})_{3}\right]\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}, \mathrm{M}^{\mathrm{III}}=\mathrm{In}(6 \mathrm{c})$, $\mathrm{Fe}(6 d)$

A CSD search, with the help of the ConQuest program (version 1.10) in the January 2008 release of the CSD version 5.29 (Allen, 1991), showed that there have been no reports on the crystal structure of compounds involving the ACCN ligand. Xray single crystal structure analysis at 123 K reveals that compounds $\mathbf{6 d}$ and $\mathbf{6 e}$ are isomorphous and crystallize in a triclinic system with the space group $P-1$ (No. 2). The asymmetric unit contains one Fe atom, half of two crystallographically independent $\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]$ ions, and half of six ACCN molecules as shown in Figure 6.9. The complex molecule is located on a general position, thus losing the crystallographic three fold symmetry in the solid state as they exist in compounds $\mathbf{6 a}$ and 6b (vide infra).

Figure 6.9 A view showing asymmetric unit with the atom numbering in $\mathbf{6 c}$. Thermal ellipsoids are drawn at the $50 \%$ probability level at 123 K . The hydrogen atoms are omitted by simplicity. $\mathbf{6 d}$ is isostructural.

The $\mathrm{Fe}-\mathrm{N}$ bond lengths in $\mathbf{6 d}$ range from 2.123(3) to $2.172(3) \AA$, and correspond closely to those in $\mathbf{6 e}$, which range from 2.125(3) to $2.2 .179(3) \AA$. These values are characteristic of the HS form of $\mathrm{Fe}(\mathrm{II})$ ions, and are comparable to those observed for the HS species in $\mathbf{6 a}$ and $\mathbf{6 b}$. The $\mathrm{Fe}-\mathrm{N}-\mathrm{C}$ bond angles range from $166.9(2)$ to $176.0(2)^{\circ}$ and $168.4(5)$ to $177.6(5)^{\circ}$ for $\mathbf{6 d}$ and $\mathbf{6 e}$, respectively, and are somewhat different from those in $\mathbf{6 a - 6 c}$. This change probably results from the steric effect of the R group in the ACCN ligand, which may compress all the $\mathrm{Fe}-\mathrm{N}-\mathrm{C}$ bond angles, resulting in a marked expansion and simplification of the lattice.

The bond distances and angles within the tetrahedral $\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]$ counter anions in $6 \mathbf{d}$ and 6e agree with those in the $\mathbf{6 a}$ and $\mathbf{6 b}$ analogues. The bond lengths and angles involving the ACCN dinitrile ligands are comparable to those for the AIBN ligands in 6a-6c.

Compounds $\mathbf{6 d}$ and $\mathbf{6 e}$ show an extended framework similar to those of $\mathbf{6 a}$ and $\mathbf{6 b}$, but more distorted, being made up of a 3-D polymeric cationic network of $\left[\mathrm{Fe}(\mathrm{ACCN})_{3}\right]^{2+}$ and uncoordinated $\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]$ anions where $\mathrm{M}=\mathrm{Fe}(\mathbf{6 c})$, In ( $\mathbf{6 d}$ ), as shown in Figure 6.10. Within the network each ACCN molecule bridges two Fe(II) ions and six ACCN molecules are coordinated to each iron(II) ion in an $S$ shaped conformation. Such a bridging fashion of the neighboring Fe(II) ions is propagated in three directions, leading to the formation of a 3-D network. Comparing the structures of $\mathbf{6 a - 6 b}$ with $\mathbf{6 d - 6 e}$, the replacement of the two methyl groups by a cyclopentane group has little effect on the overall topology. However, the $\mathrm{Fe} \cdots \mathrm{Fe}$ separations across the ACCN ligands range from $10.6461(9)$ to $12.0096(9)$ and $10.6032(17)$ to $11.9705(17) \AA$ for $\mathbf{6 d}$ and $\mathbf{6 e}$, respectively, and are significantly different to those observed in $\mathbf{6 a}$ and $\mathbf{6 b}$ (Tables 6.3 and 6.6).

Figure 6.10 (a) A view of the 3-D net in the structure of $\mathbf{6 d}$ at 123 K . Cyclopentane groups and $\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-}$counter anions are omitted for clarity. (b) Schematic presentation of the $\alpha$-Po-related net in $\mathbf{6 d}$. Inclusion of counter anions and ACCN molecules represented as space-filling model and yellow solid lines, respectively. Compound $\mathbf{6 e}$ is isostructural.

Figure 6.11 Schematic presentation in comparison of the $\alpha$-Po related net for (a) $\mathbf{6 a}-$ $\mathbf{6 b}$ and (b) $\mathbf{6 d - 6 e}$. The red spheres correspond to Fe1, sky-blue spheres to Fe 2. The ACCN or AIBN molecules are represented as yellow solid lines. Included counter anions are omitted.

In addition, similarly to that observed in compounds $\mathbf{6 a}$ and $\mathbf{6} \mathbf{b}$, there are no conventional hydrogen bonds observed in $\mathbf{6 d}$ and $\mathbf{6 e}$. There are, however, electrostatic forces and van der Waals interactions which help to stabilize the overall structures.

### 6.3.5 Magnetism

In order to characterize the spin state (HS vs LS) and any crossover spin transitions, the temperature dependent magnetic susceptibility measurements were performed over a $2-300 \mathrm{~K}$ range on freshly prepared samples. Once crystallized the sample has to be kept under a nitrogen atmosphere and put into the SQUID instrument as quickly as possible. The magnetic properties of compounds $\mathbf{6 a - 6 b}$ and
$\mathbf{6 c}-\mathbf{6 d}$ are represented in Figure 6.12 in the form of a $\chi_{M} T$ versus $T$ plot, where $\chi_{\mathrm{M}}$ is the molar magnetic susceptibility per $\mathrm{Fe}(\mathbf{6 a}, \mathbf{6 b})$ and per $3 \mathrm{Fe}(\mathbf{6 d}, \mathbf{6 e})$ and $T$ is the temperature (the plots in the forms of the effective magnetic moment, $\mu_{\text {eff, }}$ versus $T$ of compounds $\mathbf{6 a}-\mathbf{6 b}$ and $\mathbf{6 c - 6 d}$ are also provided in Figure 6.13). The magnetic behaviors of compounds $\mathbf{6 a}$ and $\mathbf{6 b}$ show that they undergo an incomplete spin transition, whereas no SCO occurs in $\mathbf{6 c}$ and $\mathbf{6 d}$ and they remain HS at all temperatures.

For 6a, $\chi_{\mathrm{M}} T$ (per Fe ${ }^{\mathrm{II}}$ ion) is equal to $3.48 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\text {eff }}=5.28 \mu_{\mathrm{B}}\right)$ at 300 K , which is the expected value for the $\mathrm{Fe}(\mathrm{II})$ ions in the HS octahedral state. Upon lowering the temperature, $\chi_{\mathrm{M}} T$ remains almost constant until 150 K , below this temperature, the $\chi_{\mathrm{M}} T$ changes sharply to attain a value of $2.15 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\mathrm{eff}}\right.$ $=4.15 \mu_{\mathrm{B}}$ ) at 100 K . It then remains practically constant down to 50 K with this $\chi_{\mathrm{M}} T$ value. In the plateau region, the compound is a mixture of HS $(S=2)$ and $\mathrm{LS}(S=0)$ states in approximately $60 \%$ HS and $40 \%$ LS. The presence of the HS state of the paramagnetic fraction is in agreement with the results of the X-ray diffraction studies. Upon further lowering of the temperature below $40 \mathrm{~K}, \chi_{\mathrm{M}} T$ decreases again, reaching a value of $1.05 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\mathrm{eff}}=2.90 \mu_{\mathrm{B}}\right)$ at 2 K . This decrease may be attributed to the zero-field splitting (ZFS) of the residual HS sites of the Fe (II) ${ }^{5} \mathrm{~A}_{2 \mathrm{~g}}$ states. In the warming mode, the $\chi_{\mathrm{M}} T$ versus $T$ is the same as observed in the cooling mode, which indicates the absence of any thermal hysteresis or thermal trapping. The $T_{\mathrm{C}}\left(=T_{1 / 2}\right)$ value of the spin transition at Fe 1 sites is 118 K .

Figure 6.12 Magnetic behavior for compounds (a) $\mathbf{6 a - 6 d}$ and (b) $\mathbf{6 b}-\mathbf{6 e}$ in the form of $\chi_{\mathrm{M}} T$ vs $T$ plots.

Figure 6.13 Magnetic behavior for compounds $\mathbf{6 a}-\mathbf{6 d}$ and $\mathbf{6 b}-\mathbf{6 e}$ in the form of $\mu_{\mathrm{eff}}$ vs $T$ plots.

For $\mathbf{6 b}, \chi_{\mathrm{M}} T$ per mol is equal to $12.3 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\text {eff }}=9.92 \mu_{\mathrm{B}}\right)$ at 250 K . This $\chi_{\mathrm{M}} T$ value in the HS form, calculated per 3 Fe ions ( $\mathrm{Fe}^{\mathrm{II}}, S=2 ; 2 \mathrm{Fe}^{\mathrm{III}}, S=5 / 2$ ) is significantly larger than that of $\mathbf{6 a}\left(\mathrm{Fe}^{\mathrm{II}}, S=2 ; 2 \mathrm{In}^{\mathrm{III}}, S=0\right)$ due to the $\mathrm{HS} \mathrm{d}^{5}$ [ $\left.\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-}$counter anions. Upon cooling, the $\chi_{\mathrm{M}} T$ values remain almost constant until ca 200 K . Below this temperature, the $\chi_{\mathrm{M}} T$ values undergo a gradual decreases at the spin transition to reach a plateau value of $c a .10 .5 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\mathrm{eff}}=9.17 \mu_{\mathrm{B}}\right)$, with a small gradual decrease between $100-50 \mathrm{~K}$, then more rapidly due to ZFS of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]^{2+}$ and $\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-} \mathrm{HS}$ centres to reach $8.8 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}$ at 10 K . No thermal hysteresis was observed in this compound. The $T_{1 / 2}$ value is $c a .170 \mathrm{~K}$, higher than in 6a. After correcting $\chi_{\mathrm{M}}$ for two HS Fe(III) ions ( $2 \times 0.0145 \mathrm{~cm}^{3} \mathrm{~mol}^{-1}$ ), the proportion of HS Fe(II) undergo SCO is $c a .50 \%$.

The magnetic behaviors of $\mathbf{6 d}$ and $\mathbf{6 e}$ are characteristic of Fe (II) compounds in the HS state in agreement with the crystal structure data. The $\chi_{\mathrm{M}} T$ value at 300 K are $3.45 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\mathrm{eff}}=5.26 \mu_{\mathrm{B}}\right)$ and $11.50 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}\left(\mu_{\mathrm{eff}}=9.59 \mu_{\mathrm{B}}\right)$ for $\mathbf{6 d}$ and 6e, respectively. These $\chi_{\mathrm{M}} T$ values are almost constant in the range $50-300 \mathrm{~K}$ and display Curie-Weiss behaviors; $\mathbf{6 d}: C=3.12 \mathrm{~cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}, \Theta=-0.87 \mathrm{~K} ; \mathbf{6 e}: C=6.28$ $\mathrm{cm}^{3} \mathrm{~K} \mathrm{~mol}^{-1}, \Theta=-0.50 \mathrm{~K}$. At the temperatures lower than $50 \mathrm{~K}, \chi_{\mathrm{M}} T$ decreases due to the occurrence of ZFS of the $S=2$ state of the HS species.

### 6.3.6 Mössbauer Spectroscopy

These spectra were measured on samples $\mathbf{6 a}$ and $\mathbf{6 b}$ by Associate Professor John D. Cashion, School of Physics, Monash University, and were used to complement the magnetic susceptibility data and shed light on the spin states and spin transitions. Spectra are shown in Figures 6.14 and 6.15, and the values of the isomer shift, $\delta$ (IS), and quadrupole splitting, $\Delta E_{Q}(\mathrm{QS})$, half-width at half-height, $\Gamma$, and area
$\%$, are given in Table 6.7. Many fitting attempts were made (eg. five different fits for 6a at 295 K ) and Table 6.7 contains the fit judged to be the most compatible with the structural and magnetic data as well as a low fitting value of $\chi^{2}$.

Figure $6.14{ }^{57} \mathrm{Fe}$ Mössbauer spectra of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{In}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}(\mathbf{6 a})$ recorded at (a) 77 and (b) 295 K .

The room temperature spectrum of $\mathbf{6 a}$ was fitted to four quadrupole doublets. Two doublets are assigned to similar HS sites and make up $73 \%$ of the area, in agreement with the crystal structure. They have typical HS isomer shifts and quadrupole splitting values, viz $\delta=1.29 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=2.38 \mathrm{~mm} \mathrm{~s}^{-1}$ (site 1) and $\delta=$ $1.22 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=2.36 \mathrm{~mm} \mathrm{~s}^{-1}$ (site 2). Surprisingly, a $14 \%$ area doublet due to LS Fe(II) was observed, in view of the magnetism, but this sometime occurs. It showed $\delta$ $=0.56 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=1.35 \mathrm{~mm} \mathrm{~s}^{-1}$. A fourth doublet with $\delta=1.13 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=$ $0.38 \mathrm{~mm} \mathrm{~s}^{-1}$ helps with the fitting but can not be assigned. At 77 K , only one HS doublet, of area $18 \%$ was resolved ( $\delta=1.30 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=3.16 \mathrm{~mm} \mathrm{~s}^{-1}$ ), the high value of $\Delta E_{Q}$ compared to the 295 K value being quite common for HS Fe(II). This agrees with the occurrence of one HS site in the structure. Interestingly, two LS doublets were resolved with a total area of $82 \%$. This does not agree with the structure or magnetism, the latter showing $40 \%$ of LS Fe(II) and $60 \%$ of HS. Factors such as the Lamb effect can make Mössbauer areas different to known spin state concentrations, but the differences here are rather large.

Complex 6b contains HS tetrahedral anions, $\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-}$, with $\delta \approx 0.2-0.3 \mathrm{~mm}$ $\mathrm{s}^{-1}, \Delta E_{Q} \approx 0.27-0.4 \mathrm{~mm} \mathrm{~s}^{-1}$ (Table 6.7). The room temperature spectrum has two other quadrupole doublets, a HS with $\delta=1.16 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=2.94 \mathrm{~mm} \mathrm{~s}^{-1}$, as the structure would suggest, and a LS with $\delta=0.57 \mathrm{~mm} \mathrm{~s}^{-1}, \Delta E_{Q}=0.70 \mathrm{~mm} \mathrm{~s}^{-1}$, the latter in tiny $\%$ area as expected. This LS line increases in intensity ( $13 \%$ ) at 77 K , and to $24 \%$ at 4.2 K , although the latter is masked by the $\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]^{-}$doublet and thus has a lower $\delta$ than expected. The HS line at 4.2 has similar $\delta$ and $\Delta E_{Q}$ values to those at 77 K (Table 6.7) and to those of $\mathbf{6 a}$. It has area ratio of 1.5:1 (HS:LS) compared to $c a$. 1:1 from the magnetism and crystal data.

In summary, the Mössbauer data are generally in agreement with the magnetic and crystal structure but there are some differences, as described above.

Figure 6.15 ${ }^{57} \mathrm{Fe}$ Mössbauer spectra of $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{Fe}^{\text {III }} \mathrm{Cl}_{4}\right]_{2}$ ( $\mathbf{6 b}$ ) recorded at (a) 4.2, (b) 77, and (c) 295 K .

Table 6.7 Mössbauer data for $\left[\mathrm{Fe}^{\mathrm{II}}(\mathrm{AIBN})_{3}\right]\left[\mathrm{M}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}, \mathrm{M}^{\mathrm{III}}=\operatorname{In}(\mathbf{6 a}), \mathrm{Fe}(\mathbf{6 b})$.

### 6.4 Conclusions

Using the polymeric approach (Kahn et al., 1998), five new $\mathrm{Fe}(\mathrm{II})$ coordination polymers containing the dinitrile bridging ligands AIBN and ACCN have been synthesized using one-pot assembly reaction, and have been structurally characterized. Four of the compound of type $\left[\mathrm{Fe}^{\mathrm{II}} \mathrm{L}_{3}\right]\left[\mathrm{Fe}^{\mathrm{III}} \mathrm{Cl}_{4}\right]_{2}$ are an exceedingly moisture-sensitive solids, thus all syntheses were carried out under a nitrogen atmosphere in order to avoid oxidation/hydrolysis. The general crystal structures consist of a 3-D $\alpha$-Po like net, except for the minor phase of a diaqua derivative $\mathbf{6 c}$ that were separated from crystals of $\mathbf{6 b}$, and it has a 2-D sheet-like structure. Of these, 6a and 6b crystallize in a highly symmetrical $R \overline{3}$ phase. There are two crystallographically independent Fe (II) octahedrally distorted sites covalently linked via the nitrile nitrogen atom of AIBN bridges molecule with the $\mathrm{Fe} \cdots \mathrm{Fe}$ separation $c a$. $10.5 \AA$. The metal atoms lie on special positions of the threefold axis as well as on inversion center. The AIBN compounds $\mathbf{6 a}$ and $\mathbf{6 b}$ are particular noteworthy in displaying an interesting SCO transition. This confirms the early prediction by Zuur and co-workers (1984). The SCO transitions were characterized by use of temperature dependent magnetic susceptibility ( $2-300 \mathrm{~K}$ ) and Mössbauer effect spectral measurements (4.2, 77 and 295 K ) together with single crystal X-ray crystallography (103 and 233 K ). The data revealed that both compounds $\mathbf{6 a}$ and $\mathbf{6 b}$ exhibit incomplete "half" SCO phenomena at $T_{1 / 2}=118$ and 170 K , respectively, with no thermal hysteresis. Only half of the $\mathrm{Fe}(\mathrm{II})$ sites (Fe1) undergo the HS $\rightarrow$ LS transition. The reason for this is not clear except to note that one Fe site (Fe1) is different, even in the all HS form, to the offer Fe site ( Fe 2 ) and might be disposed to undergo SCO. There is no accompanying crystallographic phase change; the $R \overline{3}$
phase is retained both at 103 and 233 K . A difference between $\mathbf{6 a}$ and $\mathbf{6 b}$ is of course, the anion ( $\left[\mathrm{InCl}_{4}\right]^{-}$and $\left[\mathrm{FeCl}_{4}\right]^{-}$), but there are no anion $\cdots$ cation interactions. There are also subtle changes in the conformation and torsion angles of the AIBN bridging ligang across the spin transition temperatures.

For $\mathbf{6 d}$ and $\mathbf{6 e}$, there is only one crystallographically unique of Fe (II) center, when the ACCN ligand was used instead of the AIBN ligand. Thus the symmetry of the lattice is lowered from trigonal to triclinic with a change in the space group from $R \overline{3}$ to $P \overline{1}$ phase as AIBN is replaced ACCN (vide infra). On the basis of the topological perspective, $\mathbf{6 d}$ and $\mathbf{6 e}$ have essentially the same as those found in $\mathbf{6 a}$ and 6c but more distorted. This might be caused by the size of $R$ groups on the organodinitrile ligands, i.e. dimethyl in AIBN and cyclopentane in ACCN. No SCO transition was observed in compounds $\mathbf{6 d}$ and $\mathbf{6 e}$ as evidenced by of temperature dependent magnetic susceptibility and single crystal X-ray crystallographic analysis at 123 K . The HS state of $\mathrm{Fe}(\mathrm{II})$ ion persists between $50-300 \mathrm{~K}$. At lower temperatures, the magnetism displays a typical decrease in $\chi_{\mathrm{M}} T$ due to the occurrence of zero-field splitting (ZFS) of the high spin $S=2$ states. This lack of SCO in 6 d and 6 e presumably relates to the six ACCN ligands providing a weaker octahedral ligand field at Fe (II) than do the six AIBN nitrile N -donors.

Temperature induced phase transitions are of great importance in solid state chemistry, including SCO materials, and investigation of the temperature dependence of a structure can reveal much about how structure variation affects physical properties (Herbstein, 2006). However, no compounds in the present study show temperature dependent on solid-state arrangements.

Up to now, only a few 3-D open network of Fe(II) SCO compounds have been reported. Most examples in this field are coordination polymer species based on N donating heterocyclic groups linked as a spacer (Garcia et al., 1999; Absmeier et al., 2006; 2007; Bronisz, 2007). The presented result shows that use groups of organodinitrile ligands provides a new class and significantly expands known examples of the $\mathrm{Fe}(\mathrm{II}) \mathrm{SCO}$ compounds with high dimensionality of polymeric structure. Construction of such materials creates the conditions for further investigation of the influence of the ligands, $e g$. linker group between $-\mathrm{C} \equiv \mathrm{N}$, as well as the guest counter anion molecules on the coordination polymers architecture, and also on the chemical and physical properties (magnetic, photomagnetic) of such compounds.

## CHAPTER VII

## HYDRO/SOLVOTHERMAL

## SYNTHESIS OF NEW HYBRID ORGANIC-INORGANIC VANADUIM OXIDES COMPOUNDS

### 7.1 Introduction

Framework materials based on organic-inorganic hybrids involving metal oxides and organic templates are of great contemporary interest in the fields of material science and chemical research. They have a topological diversity with a rich variety of structure types and bonding geometries (Smith, 1988; Cheetham et al., 1999; Lee et al., 2003) that allows potential applications in the fields of catalysis, magnetism, photochemistry, and sorption (Williams et al., 2000; Clearfield and Wang, 2002; Maspoch et al., 2007). In the last few years, polymers of such hybrids, particularly those involving vanadium oxide and a secondary transition metal have been made using a hydrothermal approach with an aliphatic amine as a template that provides space-filling or charge-compensation and thus acts as a structure directing agent (Chirayil et al., 1998; Chesnut et al., 1999; Hagrman et al., 2001). Many of these compounds are frameworks built from edge- and corner-sharing of $\mathrm{VO}_{4}$ tetrahedra, square $\mathrm{VO}_{5}$ pyramids, or $\mathrm{VO}_{6}$ octahedra (Zavalij and Whithingham, 1999). They have been investigated for application as secondary cathode materials (Höwing et al., 2003; Whittingham, 2004), and as oxidative catalysts (Sadakane et al., 2007).

The present work forms part of exploration of hitherto unreported organicinorganic hybrids involving vanadium oxide. One focus of this research is to use the aromatic diamine planar geometry of imidazole and hydrothermal syntheses to introduce secondary inorganic metal sites. This molecule is different from the aliphatic diamines previously used (Law et al., 2000; Law and Williams, 2000; Williams et al., 2000) in terms of basicity, size, shape, ligation ability, hydrogen bond capacity and charge and this could allow different and more diverse framework structures, Scheme 1.

Two restricted hydrogen bonding site for imidazolium

More directional hydrogen bonding could be formed for aliphatic amines

In the syntheses the inorganic-organic hybrid solids, two major types interactions are usually affecting the geometries of the structure: (i) coordination and covalent bonds connecting the metal center and appropriate ligand types, and (ii) hydrogen bonds between organic solid and the metal oxide framework. Upon protonation, the imidazolium gives a conjugate acid with $\mathrm{pKa}=6.5$. It is less base compare to ordinary aliphatic organic amines, which the pKa usually 9-11. More imidazole has to be added in order to increase the pH of the reaction mixture, and this might also affect the stoichiometric ratio of the organic moiety:metal and creates thus the structure diversity. Moreover, the imidazolium does not possesses terminal $\mathrm{NH}_{3} \mathrm{R}^{+}$ammonium ions and it offer limited hydrogen bonds forming capability due to it rigid structure in compare with normal aliphatic organoammonium, thus the structural directing effect of it is believed to behaves quite different from the ordinary straight chain aliphatic diamines.

## Scheme 1

Many hybrid organic-inorganic vanadium oxide structures have been determined by single crystal X-ray diffraction. A search of the Cambridge Structure Database (Allen et al., 1995) shows that despite many of these materials displaying disorder that effects the resulting physical properties, the structures have usually only been evaluated at room temperature. Temperature induced phase transitions are of great importance in solid state chemistry (Herbstein, 2006) and investigation of the temperature dependence of a structure can reveal much about how structure variation affects physical properties.

In this chapter report the hydro/solvothermal synthesis and characterization of five new single crystal structures of hybrids organic-inorganic vanadium oxide compounds in which parts of the inorganic frameworks are constructed by $\left\{\mathrm{VO}_{4}\right\}$ tetradedra. The compounds were $\left[\mathrm{Mn}_{3}(\mathrm{OH})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right][\mathrm{ImH}](7 \mathbf{a}),\left[\mathrm{Mn}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ (7b), $\left[\mathrm{Co}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right](7 \mathbf{c}),\left[\mathrm{Ni}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right](7 \mathbf{d})$, and $\left[\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO}) \mathrm{V}_{2} \mathrm{O}_{6}\right](7 \mathbf{e})$. The crystal structures and temperature dependence of three isomorphous of $\mathbf{7 b} \mathbf{- 7 d}$ are also investigated.

### 7.2 Experimental Section

### 7.2.1 Materials and Physical Measurements

$\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ni}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, \mathrm{V}_{2} \mathrm{O}_{5}$, and imidazole (Im) were purchased from commercial sources and used without further purification. The synthesis was carried out in a 23 ml Teflon-lined stainless autoclave under autogenous pressure with a filling capacity of about $25 \%$ (safety information for hydrothermal bomb techniques, Chainok, 2004).

The morphology of the crystalline products and heavy element (> Na) compositions were observed by a scanning electron microscope (Jeol model JSM6400 SEM) equipped with an energy dispersive X-ray fluorescence microanalyzer (WDX-100 EDX attachment). Elemental analysis was performed by Medac Ltd., UK. FTIR spectra were recorded in the range $370-4000 \mathrm{~cm}^{-1}$ on a Perkin-Elmer model Spectrum GX FTIR spectrometer using KBr pellets. The phase purity of materials was established using a PW1830 Powder X-ray diffractometer with a graphite monochromator using a $1.5418 \AA \mathrm{Cu} K \alpha$ X-radiation source at room temperature (scanning rate: $0.025 \%$; scan range: $2-55^{\circ}$ ). Thermogravimetric analysis (TGA) was performed on a Perkin-Elmer TGA 7 thermogravimetric analyzer in the air with a heating rate of $10^{\circ} \mathrm{C} / \mathrm{min}^{-1}$.

### 7.2.2 Syntheses

## Preparation of $\left[\mathrm{Mn}_{3}(\mathbf{O H})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right][\mathrm{ImH}](7 \mathrm{a})$

A single crystal of 7a suitable for X-ray crystallographic analysis was obtained by hydrothermal synthesis. A typical procedure was to mix $\mathrm{V}_{2} \mathrm{O}_{5}(0.18 \mathrm{~g}, 1.0$ mmol $), \mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.25 \mathrm{~g}, 1.0 \mathrm{mmol})$ in the presence of $\operatorname{Im}(0.40 \mathrm{~g}, 5.88$ mmol ), and then dissolve the mixture with distilled water ( $5 \mathrm{~mL}, 444 \mathrm{mmol}$ ). The solution was then stirred for two hours in air to form an orange yellow mixture. The final reaction mixture was then placed in a Teflon container, sealed in a 23 mL bomb, placed in an oven, heated from room temperature to $120^{\circ} \mathrm{C}$, and maintained at $120^{\circ} \mathrm{C}$ under autogenenous pressure for 5 days. After cooling, the product was filtered off from the bright yellow mother liquor, washed with distilled water, and dried overnight at room temperature. Orange plate like crystals of 7a was easily separated from a yellow-brown powder by hand under an optical microscope. The yield was $20 \%$ ( 0.04
g) based on $\mathrm{V}_{2} \mathrm{O}_{5}$. Anal. Found (Calcd) for $\mathrm{C}_{3} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}_{15} \mathrm{Mn}_{3} \mathrm{~V}_{4}(\mathrm{Mr}=679.69 \mathrm{~g} / \mathrm{mol})$ : C, $5.22(5.31) \%, \mathrm{H}, 0.75(0.89) \%, \mathrm{~N}, 3.96(4.13) \%$. FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 3126 \mathrm{w}, 3018 \mathrm{w}$, 2840w, 1516m, 1480w, 1431m, 1327m, 1262w, 1004m, 1042s, 901s, 752s, 625s, 564 m .

## Preparation of $\left[\mathbf{M n}(\mathbf{I m})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ (7b)

Single crystals of $\mathbf{7 b}$ were prepared following the procedure described above for 7a above. A mixture of $\mathrm{V}_{2} \mathrm{O}_{5}(0.18 \mathrm{~g}, 1.0 \mathrm{mmol}), \mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(0.25 \mathrm{~g}$, $1.0 \mathrm{mmol})$, $\operatorname{Im}(0.80 \mathrm{~g}, 11.75 \mathrm{mmol})$, and distilled $\mathrm{H}_{2} \mathrm{O}(5 \mathrm{~mL}, 444 \mathrm{mmol})$ was sealed in a 23 ml Teflon-lined stainless-steel autoclave. The brown-orange solution was heated to $120^{\circ} \mathrm{C}$ and held at $120^{\circ} \mathrm{C}$ for 5 days. After cooling, the product was filtered off, washed with distilled water, and dried overnight at room temperature. Orangeyellow block shaped crystals were easy to separate from a yellow-brown powder by hand under an optical microscope. The yield was $90 \%(0.14 \mathrm{~g})$ based on $\mathrm{V}_{2} \mathrm{O}_{5}$. Anal. Found (Calcd) for $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{MnN}_{8} \mathrm{O}_{6} \mathrm{~V}_{2} \quad(\mathrm{Mr}=679.69 \mathrm{~g} / \mathrm{mol}): \quad \mathrm{C}, \quad 27.43$ (27.45)\%, H, 2.98(3.07)\%, N, 21.37(21.34)\%. EDX; V:Mn = 2:1. FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right)$ : 3430w, 3126w, 3048w, 2942w, 2840w, 1536m, 1492w, 1480w, 1431m, 1327m, $1262 \mathrm{w}, 1094 \mathrm{~m}, 1065 \mathrm{~s}, 927 \mathrm{~s}, 790 \mathrm{~s}, 655 \mathrm{~s}, 614 \mathrm{~m}, 547 \mathrm{~m}$. TGA (under air, rate $5^{\circ} \mathrm{C}$ $\left.\min ^{-1}\right)-\Delta w\left(150-650{ }^{\circ} \mathrm{C}\right)=52.1 \%$, corresponding to loss of imidazole molecules (51.9\% theory).

## Preparation of $\left[\mathrm{Co}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right](7 \mathrm{c})$

Single crystals of $\mathbf{7 c}$ was prepared analogously to $\mathbf{7 b}$ in which $\mathrm{Co}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$ $\cdot 4 \mathrm{H}_{2} \mathrm{O}$ was used instead of $\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$. Orange-red block shaped crystals were easy to separate from a purple powder. The yield was $95 \%(0.15 \mathrm{~g})$ based on
$\mathrm{V}_{2} \mathrm{O}_{5}$. Anal. Found (Calcd) for $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{CoN}_{8} \mathrm{O}_{6} \mathrm{~V}_{2}(\mathrm{Mr}=529.13 \mathrm{~g} / \mathrm{mol})$ : C, 27.41 $(27.19) \%, \mathrm{H}, 2.92(3.04) \%, \mathrm{~N}, 21.16(21.14) \%$. EDX; V:Co $=2: 1$. FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right)$ : 3401w, 3122w, 3042w, 2935w, 2836w, 1534m, 1490w, 1479w, 1427m, 1326m, $1262 \mathrm{w}, 1091 \mathrm{~m}, ~ 1065 \mathrm{~s}, 925 \mathrm{~s}, 788 \mathrm{~s}, 654 \mathrm{~s}, 612 \mathrm{~m}, 546 \mathrm{~m}$. TGA (under air, rate $5^{\circ} \mathrm{C}$ $\left.\min ^{-1}\right)-\Delta w\left(175-630{ }^{\circ} \mathrm{C}\right)=52.0 \%$, corresponding to loss of imidazole molecules (51.5\% theory).

## Preparation of $\left[\mathrm{Ni}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ (7d)

Single crystals of $7 \mathbf{d}$ was prepared analogously to $\mathbf{7 b}$ in which $\mathrm{Ni}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2}$ $\cdot 4 \mathrm{H}_{2} \mathrm{O}$ was used instead of $\mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$. Blue block shaped crystals were easy to separate from a brown blue powder. The yield was $90 \%(0.14 \mathrm{~g})$ based on $\mathrm{V}_{2} \mathrm{O}_{5}$. Anal. Found (Calcd) for $\mathrm{C}_{12} \mathrm{H}_{16} \mathrm{NiN}_{8} \mathrm{O}_{6} \mathrm{~V}_{2}(\mathrm{Mr}=528.90 \mathrm{~g} / \mathrm{mol}): \mathrm{C}, 26.97$ (27.25)\%, H, 2.97(3.05)\%, N, 21.07(21.19)\%. EDX; V:Ni = 2:1. FTIR $\left(v_{\text {max }} / \mathrm{cm}^{-1}\right)$ : 3991w, 3118w, 3039w, 2931w, 2834w, 1533m, 1488w, 1473w, 1425m, 1324m, $1262 \mathrm{w}, 1089 \mathrm{~m}, 1065 \mathrm{~s}, 924 \mathrm{~s}, 787 \mathrm{~s}, 654 \mathrm{~s}, 611 \mathrm{~m}, 541 \mathrm{~m}$. TGA (under air, rate $5^{\circ} \mathrm{C}$ $\left.\min ^{-1}\right)-\Delta w\left(180-625{ }^{\circ} \mathrm{C}\right)=51.9 \%$, corresponding to loss of imidazole molecules (51.5\% theory).

## Preparation of $\left[\mathbf{M n}(\mathrm{DMSO})(\mathrm{Im})_{3} \mathbf{V}_{2} \mathrm{O}_{6}\right](7 \mathrm{e})$

Using the same stoichiometric ratio of the $\mathrm{V}_{2} \mathrm{O}_{5}, \mathrm{Mn}\left(\mathrm{CH}_{3} \mathrm{COO}\right)_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}$, and Im and reaction condition as in $\mathbf{7 b}$, but with the solvent changed from distilled $\mathrm{H}_{2} \mathrm{O}$ to DMSO ( $2 \mathrm{~mL}, 20.2 \mathrm{mmol}$ ), yellow-brown plate like crystals were obtained and separated from a brown powder. The yield was $90 \%(0.17 \mathrm{~g})$ based on $\mathrm{V}_{2} \mathrm{O}_{5}$. Anal. Found (Calcd) for $\mathrm{C}_{11} \mathrm{H}_{18} \mathrm{MnN}_{6} \mathrm{O}_{7} \mathrm{~S}_{1} \mathrm{~V}_{2}$ ( $\mathrm{Mr}=535.20 \mathrm{~g} / \mathrm{mol}$ ): C, 24.41(24.69) $\%, \mathrm{H}$, 2.92(3.39)\%, N, 15.64(15.70)\%.EDX; V:Mn=2:1. FTIR $\left(v_{\max } / \mathrm{cm}^{-1}\right): 3430 \mathrm{w}, 3126 \mathrm{w}$,

3048w, 2942w, 2840w, 1536m, 1492w, 1480w, 1431m, 1327m, 1262w, 1094m, $1065 \mathrm{~s}, 927 \mathrm{~s}, 787 \mathrm{~s}, 655 \mathrm{~s}, 614 \mathrm{~m}, 547 \mathrm{~m}$. TGA (under $\mathrm{N}_{2}$, rate $5^{\circ} \mathrm{C} \mathrm{min}^{-1}$ ) $-\Delta w(195-$ $670{ }^{\circ} \mathrm{C}$ ) $=50.3 \%$, corresponding to loss of organic molecules ( $49.8 \%$ theory).

### 7.2.3 X-Ray Crystallographic Study

Single crystal X-ray data were collected either on a Bruker SMART APEX 1000 CCD diffractometer (HKUST) or on an Enraf-Nonius KappaCCD diffractometer (SUT and ANU). Reflection intensities were collected using graphite monochromated Mo $K \alpha$ radiation $(\lambda=0.71073 \AA)$. Structures were solved by direct methods and expanded using Fourier techniques. The structures were refined by full matrix on $F^{2}$ by SHELXTL (Sheldrick, 1997) for 7a and 7e or on $F$ with use of RAELS06 (Rae, 2006) for 7b-7d. In the final cycles of refinement, all atoms except hydrogen atoms and disordered molecules were refined anisotropically. However, special crystal structure refinement details for each compound are described below.

7a: The imidazolium molecules were found to be disordered, and were modeled in two different orientations. The total occupancy of both orientations was fixed to one. Restraints were applied to the displacement parameters of this disordered molecule.

7b-7d: Refinement of the low temperature $I 4_{1} / a$ phase used origin choice 2 of the International Tables for X-ray Crystallography, Vol. A (Hahn, 1995), and 317 variables to describe 64 non hydrogen atom positions and 36 hydrogen atom positions. A separate scale constant for reflections with $l$ odd was added for the Co structure. The second of eight imidazoles in the asymmetric unit was found to be disordered. All hydrogen atoms were reinserted in geometrically sensible positions after each refinement cycle and given atom displacement parameters defined by the

12 variable $T L$ rigid body model (Rae, 1975) that described the anisotropic atom displacement parameters of the corresponding imidazole (or disordered imidazole). The centres of action for the librations were located on the associated $M$ atom. A common set of refinable local orthonormal coordinates were used to impose equal planar geometry on every imidazole, their origins and orientations being independently determined. The 2 -fold rotation related components of the disordered imidazole were constrained to be coplanar with the coordinating nitrogens coincident. The metal atoms and oxygen atoms were refined as isolated anisotropic atoms. Atoms $M 2$ and $M 3$ lie on 2 -fold axes.

Refinement of the high temperature $P 4_{2} / n$ phases used origin choice 2 (Hahn, 1995), and 174 variables to describe 40 non hydrogen atom positions and 24 hydrogen atom positions. The first and second of the four imidazoles in the asymmetric unit were described as $1: 1$ disordered and given labels 1 a and 1 b , and 2 a and 2 b . All other atoms were modelled as being ordered. All hydrogen atoms were reinserted in geometrically sensible positions after each refinement cycle and given atom displacement parameters defined by the rigid body models for the atoms to which they were attached. The two disordered imidazoles are attached to the $M 1$ atom and their atoms were modelled to have a common $T$ rigid model parametrisation plus individual librations about the relevant $M 1-\mathrm{N}$ bonds. The other two imidazoles were attached to $M 2$ and were also modelled to have a common $T$ rigid model parametrisation plus individual librations about the relevant $M 2-\mathrm{N}$ bonds. A common set of refinable local orthonormal coordinates were used to impose equal planar geometry on every imidazole, their origins and orientations being independently determined. Restraints were used to match the $M 1-\mathrm{N}$ bond distances of each
component of a disordered imidazole. Restraints were also used to initially restrain second nearest neighbour $M 1-\mathrm{C}$ distances but these restraints were reduced to minimal importance in the final refinement cycle. The metal atoms and oxygen atoms were refined as isolated anisotropic atoms. Atoms $M 1$ and $M 2$ lie on 2-fold axes.

For $M=\mathrm{Ni}$, the low temperature $P 2 / n$ phase was described using 287 variables to describe 60 non-hydrogen atoms and 32 hydrogen atom positions in the asymmetric unit. Only the sixth of eight imidazoles is not hydrogen bonded and a mixed scattering factor description was used to justify the atom labeling. A model for C62 as $\left(1-\delta_{1}\right) \mathrm{f}_{\mathrm{C}}+\delta_{1} \mathrm{f}_{\mathrm{N}}$ and N 62 as $\left(1-\delta_{2}\right) \mathrm{f}_{\mathrm{C}}+\delta_{2} \mathrm{f}_{\mathrm{N}}$, where $\delta_{1}+\delta_{2}=1$ gave $\delta_{1}=0.035$ (25). All hydrogen atoms were reinserted in geometrically sensible positions after each refinement cycle and give atom displacement parameters defined by the rigid body models applying to the atoms to which they were attached. In the asymmetric unit, pairs of imidazoles are attached to non equivalent Ni atoms on 2-fold axes and were given rigid body $T$ model parameters constrained by this symmetry (Rae, 1975). Additional $L$ model parameters (6 per imidazole) centered on the relevant Ni were also included to describe the imidazole atom displacement parameters by $4 \times(4+2 \times$ $6)=64$ variables. A common set of refinable local orthonormal coordinates were used to impose equal planar geometry on the imidazoles, their origins and orientations being independently refined. No restraints were used. The metal and oxygen atoms were refined as independent anisotropic atoms. The crystals were found to be 0.746 (3):0.254 twinned assuming a $90^{\circ}$ rotation about $\mathbf{b}$ as the twinning operation and allowing for the overlap of adjacent reflections modeling the observed intensity using the function $Y=0.746$ (3) $\left|F_{1}\right|^{2}+0.254 P\left|F_{2}\right|^{2}$ where $P=0.5-0.5 \sin \left(\pi\left(d-d_{0}\right) / 2 d_{0}\right)$
if $d<2 d_{0}, 0$ otherwise. $d$ is the separation in reciprocal space of overlapping twin component reflections and $d_{\mathrm{o}}$ was refined to be $0.1397(5) a^{*}$.

The data collection and structure refinement details for $7 \mathbf{a}-7 \mathbf{e}$ at selected temperatures are listed in Tables 7.1-7.4. Detailed refinement statistics for 7b-7d are given in Table 7.5. Other crystallographic data of compounds $\mathbf{7 a}-\mathbf{7} \mathbf{e}$ are given as supplementary material in the CIF which can be found on the attached CD-ROM.

Class 1: Reflection with $I>3 \sigma(I)$ and $h+k+l$ even. Class 2: Reflection with $I>3 \sigma(I)$ and $h+k+l$ odd. Class 3: Reflection all with $I<3 \sigma(I)$ and not included in the refinement. Average of $F^{2}$ for Class 2 relative to Class 1 is $0.111(100(2) K), 0.098(200(2) K)$, and $0.082(279(2) K)$ for $7 \mathbf{b}, 0.066(100(2) K)$, and $0.044(170(2) K)$ for $7 \mathbf{c}$.

### 7.3 Results and Discussion

### 7.3.1 Syntheses and Characterization

The temperature of the reaction is of crucial importance for the crystallization of M/V/O/imidazole products. Experiments conducted at temperatures between 160 and $200^{\circ} \mathrm{C}$ gave black brown powders that do not contain imidazole, as verified by IR studies. These materials were not characterized further. However, maintaining the temperature of the crystallization reaction between 110 and $120{ }^{\circ} \mathrm{C}$ generally gave two product components (a crystalline material and powder). Therefore, in this study temperature of reactions of vanadium oxide with a secondary metal in the presence of imidazole was generally controlled near $120^{\circ} \mathrm{C}$ to produce nice crystalline products. Time also played an important role affecting the morphology and particle size of crystallized products. To grow single crystals with dimensions $0.2-0.4 \mathrm{~mm}$, suitable for X-ray crystallography, it is necessary to increase the reaction time, typically to 4-5 days.

In order to assignment of single crystal for analyzed with a laboratory X-ray crystallography, SEM is also one of powerful method to provided a good indication of single crystal character. SEM pictures of compounds 7a-7e are shown in Figure 7.1. The morphology of a single crystals of 7a are often intergrown plate like crystal with size of $c a .1 .0-2.0 \mathrm{~mm}$. Beside, $\mathbf{7 b}-7 d$ are observed to be similar that in hexagonalshaped single crystals with particle diameter of $c a .1 .0-2.0 \mathrm{~mm}$, whilst that of 7 e are stacked in a random fashion $c a .0 .5-1.0 \mathrm{~mm}$ in size. It is evidence that these particles are particularly clear and large enough to be determining with a single crystal X-ray diffractometer. In addition, forall compounds the EDX analysis confirmed the presence of M and V in $c a .1: 2$ ratio in crystalline materials.

Figure 7.1 SEM pictures of (a) 7a, (b) 7b, (c) 7c, (d) 7d, and (e) 7e.

The balanced chemical equations representing the syntheses of the products do not always correspond to the actual stoichiometric ratio of the reactants that are required to maximize the product yields. This is not surprising as other products are also formed. There are at least five factors which influence the composition and structure of the reaction products: stoichiometry, temperature, reaction times, concentration, and pH . Although we were not able to clarify fully the effect of each of these factors, some distinct tendencies were observed from the many synthetic trials. The conditions reported in the sample preparation section are optimum for preparing the compounds in highly crystalline form. The compounds are phase pure by microscopic examination, microelemental analysis, and powder X-ray diffraction. As
shown in Figure 7.2, the room temperature PXRD patterns of bulk materials of compounds correspond well in position with the simulated one on the basis of the single crystal data, indicating the phase purity of the synthesized sample.

Figure 7.2 Simulation and experiment PXRD patterns of 7a, 7b, and 7e. 7c and 7d are isostructure to $\mathbf{7 b}$.

### 7.3.2 Structural Description of $\left[\mathrm{Mn}_{3}(\mathrm{OH})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right][\mathrm{ImH}](7 \mathrm{a})$

Compound 7a crystallizes in the centrosymmetric triclinic space group $P \overline{1}$ with $Z=1$. The structure consists of an open 3-D anionic framework which is charged balance by imidazolium cations. The asymmetric unit contains sixteen non-hydrogen atoms, out of which twelve belong to the inorganic framework and five to the protonated aromatic amine ligand, Figure 7.3. There are two crystallographically
independent vanadium atoms and two distinct manganese atoms. The oxidation states of the metals are determined by bond valence sum (Brown and Altermatt, 1985; Brese and O'Keeffe, 1991) to be $\mathrm{Mn}^{\mathrm{II}}, \mathrm{Mn}^{\mathrm{III}}$, and $\mathrm{V}^{\mathrm{V}}$. Therefore, $7 \mathbf{7}$ is a mixed-valence manganese metal. The Mn-O bond distances vary from 1.895(4) to 2.225(4) $\AA$ (mean $2.087 \AA$ ) and the $\mathrm{V}-\mathrm{O}$ distances in the range $1.639(4)-1.799(4) \AA$ (mean $1.716 \AA$ ). Selected interatomic bond lengths for compound $7 \mathbf{7 a}$ are given in Table 7.6.

Figure 7.3 Ball and strict representation of the asymmetric unit with numbering scheme and showing the coordination environments of the metal centres in $\mathbf{7 a}$. The two orientations of the disordered of imidazolium are shown in different colors. Symmetry codes: (i) $-x, 1-y,-1-z$; (ii) $1-x,-y$, $-1-z$; (iii) $-x,-y,-1-z$; (iv) $-1+x, y, z$.

${ }^{a}$ Estimated standard deviations are given in parentheses.
Symmetry codes: (i) $1-x,-y,-1-z$; (ii) $-x,-y,-1-z$; (iii) $x, y, z-1$.

The anionic framework of 7a comprises of 1-D ladder chains of $\left[\mathrm{Mn}_{3}\right]$ trimer blocks. The Mn ladders are then linked together into a 3-D structure by tetravanadate $\left[\mathrm{V}_{4} \mathrm{O}_{13}\right.$ ] units along the crystallographic $a$ axis, as shown in Figure 7.4a. The formation of an open 3-D framework can alternatively be described as constructed by the secondary building unit (SBU) of $\mathrm{Mn}_{3} \mathrm{~V}_{4} \mathrm{O}_{24}$ clusters in which this cluster is built by $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{MnO}_{6}$ octahedra linked through their edges and corners. The cluster of the SBU is capped together in the $b$ axis to form the 2-D layer and further connected by $\mathrm{V}-\mathrm{O}-\mathrm{V}$ linkages forming the 3-D structure, which possesses 1-D channels, as depicted in Figure 7.4b. These hydrophilic channels are ten-membered rings and occupied by disordered imidazolium cations. As shown in Figure 7.5, the channel dimensions are approximately $7.9 \times 10.2 \AA$. This channel is somewhat longer when comparing to the most common zeolites such as mordenite $(5.3 \times 8.4 \AA)$ and stilbite $(5.3 \times 8.3 \AA)$, and those of AlPO families such as AlPO-C $(5.6 \times 8.4 \AA)$ and AlPO-D (4.8 $\times 9.0 \AA$ ). The imidazolium molecules are in close proximity and form

Figure 7.4 (a) Polyhedral and ball-and-stick representation of 7 a viewed approximately
along the $a$ axis, and (b) wires/stick and space-filling representation viewed along the $b$ axis of 7a. The disordered imidazolium molecules are located in the middle of the channels.

Figure 7.5 Perspective views of (a) polyhedral and (b) space-filling representations of anionic framework in 7a along the crystallographic $a$ axis.
$\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond interactions to the inorganic framework, thus, playing a crucial role in the stability of the open framework structure in 7a. The $(\mathrm{D} \cdots \mathrm{A})$ distances are in the range $2.777(3)-3.125(3) \AA$ and $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ angles $>140^{\circ}$.

### 7.3.3 Investigation of the Structure and Phase Transitions of $\left[M(\operatorname{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]_{\infty}, M=$ Mn (7b), $\mathbf{C o}$ (7c), $\mathbf{N i}$ (7d)

Largest principal libration tensor for the imidazoles of the low and high temperature phases are summarized in Tables 7.7 and 7.8. Angle between normals to planes of pseudo symmetry related imidazoles for the low and high temperature phases of the compounds $\mathbf{7 b}-7 \mathbf{c}$ are given in Tables 7.9 and 7.10. Selected bond lengths at $100(2) \mathrm{K}$ for the compounds $\mathbf{7 b}$ and $\mathbf{7 c}$ are listed in Tables 7.11 and 7.12. The hydrogen bonding at $100(2)$ and $295(2) \mathrm{K}$ is described in Tables 11 and 12. The bond lengths and angles, hydrogen bonds geometry, and other crystallographic data at all experiment temperatures are given as supplementary material in the CIF which can be found on the attached CD-ROM.

## Structural Description of the $I 4_{1} / a$ Phase

Compounds $\mathrm{C}_{12} \mathrm{H}_{16} M \mathrm{~N}_{8} \mathrm{O}_{6} \mathrm{~V}_{2}, M=\mathrm{Mn}(7 \mathbf{b}), \mathrm{Co}(7 \mathbf{c}), \mathrm{Ni}(7 \mathbf{d})$, have isomorphous structures. The room temperature structure $(Z=8)$ in space group $P 4_{2} / n$ (No. 86) is reversibly transformed to a body centred structure $(Z=32)$ in space group $I 4_{1} / a$ (No. 88) at $281(2) \mathrm{K}$ for $\mathbf{7 b}$ and $175(2) \mathrm{K}$ for $7 \mathbf{c}$. The asymmetric unit along with the atomic numbering for the $I 4_{1} / a$ structures are shown in Figure 7.6a. This Figure is drawn for $\mathbf{7 b}$ down a direction $10^{\circ}$ away from $\mathbf{a}+\mathbf{b}$ with $\mathbf{c}$ vertical. In the $P 4_{2} / n$ phase the two halves of the asymmetric unit become related by a 2 -fold rotation axis parallel to $\mathbf{c}$ and passing through $M 1$. Four crystallographically independent $\mathrm{VO}_{4}$ tetrahedra
are in general positions. Atoms $M 2$ and $M 3$ lie on 2-fold rotation axes that contain -4 sites. Atom $M 1$ lies approximately on a $4_{1}$ screw axis that corresponds to a $4_{2}$ axis in the $P 4_{2} / n$ structure. There are eight imidazole groups, seven of which are involved in hydrogen bonding. The imidazol labeled with a 2 is not hydrogen bonded, and is disordered with occupancy ratios that refined to $7 \mathbf{7 b}: 0.776(11): 0.224$ at $100(2) \mathrm{K}$, $0.698(12): 0.302$ at $200(2) \mathrm{K}, 0.618(13): 0.382$ at $279(2) \mathrm{K}$, and 7c: $0.425(15)$ : 0.575 at $100(2) \mathrm{K}, 0.389(18): 0.611$ at $170(2) \mathrm{K}$.

The coordination polyhedra observed for the four vanadium atoms exhibit distorted $\left[\mathrm{VO}_{4}\right]$ tetrahedral coordination geometry with three $\mu_{2}-\mathrm{O}$ atoms and a terminal oxygen atom. The bond valence sums (Brown and Altermatt, 1985; Brese and O'Keeffe, 1991) indicate that all the vanadium is pentavalent. Each vanadium tetrahedron is connected via $\mu_{2}-\mathrm{O}$ atoms. The pair (V1 and V2), likewise (V3 and V4), are mutually linked together through corner sharing of $\mu_{2}-\mathrm{O}$ atoms ( O 2 and O5), likewise ( O 8 and O 11 ) to form $\left[\mathrm{V}_{4} \mathrm{O}_{12}\right]^{4-}$ tetranuclear rings about a centre of inversion. This anionic cluster of $\left[\mathrm{V}_{4} \mathrm{O}_{12}\right]^{4-}$ resembles the prototypical structure observed in $\left(\mathrm{Bu}_{4} \mathrm{~N}\right)_{3} \mathrm{HV}_{4} \mathrm{O}_{12}$ (Fuchs et al., 1976), and $\left(\mathrm{PPh}_{4}\right)_{2} \mathrm{~V}_{4} \mathrm{O}_{11}$ (Sharma et al., 2002). The O3, O6, O9, and O12 atoms are terminal. The remaining oxygens of O1, $\mathrm{O} 4, \mathrm{O} 7$, and O 10 connect the relevant $\mathrm{VO}_{4}$ tetrahedron to a $M$ atom that displays a distorted octahedral geometry coordinated through a nitrogen donor to four imidazole groups atoms in an equatorial plane and two oxygen atoms from the anionic $\left[\mathrm{V}_{4} \mathrm{O}_{12}\right]$ clusters in axial positions. The metal atoms are not coplanar with respect to the imidazoles and this presumably is to satisfy packing and hydrogen bonding demands.

(a)

(b)

Figure 7.6 Shows the asymmetric unit of (a) the $I 4_{1} / a$ at $100(2) \mathrm{K}$, and (b) the $P 4_{2} / n$ at $295(2) \mathrm{K}$ structures of 7 a down equivalent directions with 50 and $25 \%$ displacement ellipsoids, respectively. Environment on the right of the 2fold axis in Figure 7.6a transforms to the environment as depicted the left of the axis. Hydrogen atoms are omitted for clarity.

Figure 7.7a shows a single layer of the $I 4_{1} / a$ structure at $z=1 / 2$ projected down the $\mathbf{c}$ axis. The framework consists of cyclic $\left[\mathrm{V}_{4} \mathrm{O}_{12}\right]$ tetramers interconnected by $M \mathrm{~N}_{4} \mathrm{O}_{2}$ octahedra. The topology of framework is defined by two cyclic sub-motifs, namely, four $\mathrm{VO}_{4}$ tetrahedra corner connected to form a eight membered $\left\{\mathrm{V}_{4} \mathrm{O}_{4}\right\}$ small rings, and the four $M \mathrm{~N}_{4} \mathrm{O}_{2}$ octahedra and eight $\mathrm{VO}_{4}$ tetrahedra further connected to form a twenty four membered $\left\{M_{4} \mathrm{~V}_{8} \mathrm{O}_{12}\right\}$ large rings. The $4_{1}$ screw axis causes the centres of the small and large rings to alternate along the $\mathbf{c}$ direction with $1 / 4 \mathbf{c}$ spacing (ca. $7.4 \AA$ ). Eight imidazoles connected to four different $M$ atoms fill cavities centred on pseudo inversion centres. Views of a polyhedral representation, showing 2-D layer of $I 4_{1} / a, P 4_{2} / n$, and $P 2 / n$ structures are illustrated in Figure 7.8 in which coordinated imidazole ligand project outside the bimetallic oxide layers are omitted.

Figures 7.9 a and 7.9 b show the environment about such a site $3 / 4,1 / 4,1 / 2$. The pseudo inversion relates imidazoles equivalent to those labeled $1,2,3$, and 4 to those labeled $5,6,7$, and 8 , respectively. The available hydrogen attached to the non metal-coordinated nitrogen of the imidazole is involved in hydrogen bonding to an oxygen atom for all imidazoles except that labeled 2 . The bond connectivity is centrosymmetric for all the imidazoles except those labeled 2 and 6 . The hydrogen bonds are of similar length (ca. $2.8 \AA$ ) and connect equivalents of N12, N32, N42, N52, N62, N72, and N82 to equivalents of O12, O11, O3, O6, O9, O5, and O9, respectively. However only the orientations of the imidazoles labeled 3 and 7 maintained a reasonably exact inversion relationship.

Figure 7.7 Polyhedral representations of single layer of compounds at (a) $I 4_{1} / a$ and
(b) $P 4_{2} / n$, viewed along the crystallographic $\mathbf{c}$ axis. The layers are at $z=$ $1 / 2$ for $I 4_{1} / a$, and $z=1$ for $P 4_{2} / n$.

Figure 7.8 Polyhedral representations of inorganic layers of compounds at (a) $I 4_{1} / a$ for $7 \mathbf{b}$ and $7 \mathbf{c}$, (b) $P 2 / n$ for $7 \mathbf{d}$, and (c) $P 4_{2} / n$ for $7 \mathbf{b}-7 \mathbf{c}$.

Figure 7.8 (Continued)

## Description of the $\mathrm{P4}_{\mathbf{2}} / \boldsymbol{n}$ phase

The high temperature phase crystallizes in space group $P 4_{2} / n$ (no. 86), with eight formula units per unit cell. The asymmetric unit is illustrated in Figure 7.6b for 7b, and is related to the asymmetric unit of the $I 4_{1} / a$ phase by the transformation $x_{\mathrm{P}}=$ $x_{\mathrm{I}}+y_{\mathrm{I}}-1, y_{\mathrm{P}}=-x_{\mathrm{I}}+y_{\mathrm{I}}+1, z_{\mathrm{P}}=2 z_{\mathrm{I}}$ and occupies half the volume. This corresponds to relating two axial systems with a common origin so that $\mathbf{a}_{\mathrm{P}}=1 / 2\left(\mathbf{a}_{\mathrm{I}}+\mathbf{b}_{\mathrm{I}}\right), \mathbf{b}_{\mathrm{P}}=1 / 2\left(-\mathbf{a}_{\mathrm{I}}\right.$ $\left.+\mathbf{b}_{\mathrm{I}}\right), \mathbf{c}_{\mathrm{P}}=1 / 2 \mathbf{c}_{\mathrm{I}}$. Figures 7.6a and 7.6b are drawn down the same direction. What was a $4_{1}$ screw axis passing approximately through $M 1$ is now a $4_{2}$ screw axis containing a 2-fold rotation that relates two asymmetric units. Atoms $M 1$ and $M 2$ both lie on 2-fold axes. $M 2$ is on an axis containing -4 sites. The coordination geometry around the metal centres is identical to the low temperature $I 4_{1} / a$ phase.

Figure 7.9 Hydrogen bonds about the pseudo inversion centers $3 / 4,1 / 4,1 / 2$ for the $I 4_{1} / a$ structure at $100(2) \mathrm{K}$ of (a) $7 \mathbf{b}$, (b) $7 \mathbf{c}$, and $0,1 / 2,1$ for the $P 4_{2} / n$ structure at 295(2) K of (c) $\mathbf{7 b}$, (d) $\mathbf{7 c}$. The $1: 1$ disorder of the $P 4_{2} / n$ structure is not shown.

Figure 7.9 (Continued).

The imidazoles 1 and 2 attached to $M 1$ were each disordered over two positions whereas this was found to be unnecessary for imidazoles 3 and 4 attached to M2. Again the metal atoms were not constrained to lie in the plane of the attached imidazoles. The occupancy refinement suggested ratios of $1: 1$ which were subsequently fixed.

The hydrogen bond connectivity is equivalent to the $I 4_{1} / a$ phase if one simple imposes exact inversions in the centre of the cavities containing eight imidazoles as required by the space group $P 4_{2} / n$. Figures 7.9 c and 7.9 d shows the environment of the cavity at $0,1 / 2,1$, after ordering across the inversion centre to best approximate the $I 4_{1} / a$ phase, imidazoles 1 to 8 of $I 4_{1} / a$ phase corresponding to imidazoles $1 \mathrm{~b}, 2 \mathrm{a}$, $3,4,1 \mathrm{a}, 2 \mathrm{~b}, 3,4$ of $P 4_{2} / n$ phase. It is seen that the major difference between the two phases is that imidazoles 4 and 8 that were not inversion equivalent in the $I 4_{1} / a$ phase have joined imidazoles 3 and 7 in becoming inversion related in the $P 4_{2} / n$ phase. To switch between inversion related descriptions of the cavity only requires a change in the hydrogen bond connectivity for imidazoles 2 and 6,2 becoming hydrogen bonded and 6 losing its hydrogen bond. The other changes simply involve reorienting the imidazoles without a change of hydrogen bond connectivity.

The description of the $\mathrm{P4}_{2} / n$ phase has departed from the model implied by disordering the $I 4_{1} / a$ structure so as to simplify the refinements allowing each of the refinements above the transition temperature to have a well behaved refinement. We have ignored the inherent coplanar disorder of imidazole 2 in the $I 4_{1} / a$ structure. Likewise imidazoles 3 and 4 of the $P 4_{2} / n$ structure should in principal be replaced by pairs of half occupancy imidazoles. Instead we rely on rigid body atom displacement parameters to indicate what is going on.

Columns parallel to $\mathbf{c}$ direction of imidazoles attached to $M 1$ are propagated by $4_{1}$ and $4_{3}$ screw axes. The inversion centres within the cavities containing eight imidazoles obviously applies almost exactly in the ordered cavity model for imidazoles 3 and 4, blocking communication between columns parallel to $\mathbf{c}$ direction of imidazoles attached to $M 1$ in the $P 4_{2} / n$ structure. The ability to switch between the inversion related environments of a cavity only exists above the transition temperature and the requirements to become ordered in space group $I 4_{1} / a$ is revealed by studying the $P 4_{2} / n$ structure just above the transition point.

## Structural Description of the $\mathbf{P 2} / \mathbf{n}$ Phase

The ordering of the disordered $P 4_{2} / n$ structure to create a $P 2 / n$ structure allows the lost $4_{2}$ symmetry operation to create twinned components related by a $90^{\circ}$ rotation about the monoclinic axis. Imidazoles 1 to 8 of the $P 2 / n$ asymmetric unit correspond to imidazoles $1 \mathrm{a}, 2 \mathrm{~b}, 3,4,1 \mathrm{~b}, 2 \mathrm{a}, 3,4$ of the $P 4_{2} / n$ asymmetric unit. Rings 1 to 4 are obtained by the transformation $x=x_{\mathrm{p}}, y=z_{\mathrm{p}}, z=y_{\mathrm{p}}$ and imidazols 5 to 8 are obtained by a further transformation $x^{\prime}=-z+1, y^{\prime}=y-1 / 2, z^{\prime}=x+1 / 2$. Imidazoles 1 to 4 and their inversion equivalents create a centrosymmetric cavity in which all eight imidazoles are involved in hydrogen bonding whereas imidazoles 5 to 8 and their inversion equivalents create a centrosymmetric cavity in which only six imidazoles are involved in hydrogen bonding. Imidazole 6 is not used for hydrogen bonding. Figures 7.10a and 7.10 b show the hydrogen bonds about the inversion centers at 0,1 , $1 / 2$ and $1 / 2,1 / 2,1 / 2$, respectively. The angles between the normals to the imidazole planes for rings 5 to 8 and rings 1 to 4 transformed by the pseudo symmetry operation $-z+1, y-1 / 2, x+1 / 2$ are $48.0^{\circ}(1,5), 71.3^{\circ},(2,6), 1.4^{\circ}(3,7)$, and $13.6^{\circ}(4,8)$ at $100(2)$ K respectively.

Figure 7.10 Hydrogen bonds about the inversion centres (a) $0,1,1 / 2$, and (b) $1 / 2,1 / 2$, $1 / 2$ for the ordered $P 2 / n$ structure of 7 d at $100(2) \mathrm{K}$.

## Change of Structure with Temperature

The cell dimensions for each temperature are given in Tables 7.2-7.4. Although the unit cell volume decreases with decrease in temperature, (7b, $V=$ $3962.7(1) \AA^{3}$ at $295(2) \mathrm{K}, 3953.4(1) \AA^{3}$ at $283(2) \mathrm{K}, V / 4=3948.5(1) \AA^{3}$ at $279(2) \mathrm{K}$, $3937.6(1) \AA^{3}$ at 200(2) K, 3926.7(1) $\AA^{3}$ at $100(2) \mathrm{K} ; 7 \mathbf{c}, V=3864.7(1) \AA^{3}$ at $295(2) \mathrm{K}$, 3845.04(9) $\AA^{3}$ at $180(2) \mathrm{K}, V / 4=3832.8(1) \AA^{3}$ at $170(2) \mathrm{K}, 3823.6(1) \AA^{3}$ at $100(2) \mathrm{K}$; $7 d, V=3820.27(1) \AA^{3}$ at $295(2) \mathrm{K}$, and $3788.63(1) \AA^{3}$ at $100(2) \mathrm{K}$ ), the $\mathbf{c}$ axis actually increases sharply near the $P 4_{2} / n$ to $I 4_{1} / a$ transition temperature when approached from above (7b, $c=14.8030(2) \AA$ at 295(2) K, 14.8304(2) $\AA$ at 283(2) K, $c / 2=14.8448(2) \AA$ at $279(2) \mathrm{K}, 14.8261(2) \AA$ at $200(2) \mathrm{K}, 14.8002(2) \AA ; 7 \mathbf{c}$, $14.6057(2) \AA^{3}$ at $295(2) K, 14.5532(2) \AA^{3}$ at $180(2) K, c / 2=14.6350(2) \AA$ at $170(2)$ $\mathrm{K}, 14.6329(2) \AA$ at $100(2) \mathrm{K} ; 7 \mathrm{~d}, 14.5589(2) \AA^{3}$ at 295(2) K, 14.3657(2) $\AA$ at $100(2)$ K). It should be pointed out that the transition temperature for the Co structure was not as well defined as for the Mn structure, presumably because the smaller unit cell for the Co structures causes what may be described as a "sticking gate effect". The low temperature Co structure persists above the transition temperature if the unit cell is determined within ten minutes and the high temperature structure has similar persistence below the transition temperature.

Indeed the low temperature Co structure was shown to have stacking faults requiring the use of two scale constants, $\mathrm{K}_{1}$ for $l$ even and $\mathrm{K}_{2}$ for $l$ odd, where $\mathrm{K}_{2} / \mathrm{K}_{1}=$ $0.819(4)$ at $100(2) \mathrm{K}$ and $0.653(5)$ at $170(2) \mathrm{K}$. No such adjustments to the low temperature Mn structure (7b) was necessary. The 170(2) K structure of Co (7c) is not as good as the other refinements and one suspect that $\mathrm{K}_{2}$ may have been varying with time during data collection. Residual peaks on the heavy atoms, most noticeable when
a single scale is used, persist to a lesser extent for the 170(2) K structure but not the 100(2) K structure.

The largest principal values of the libration tensor in radians ${ }^{2}$ for each imidazole ring are given in Tables 7.7 and 7.8, using the labelling of the $I 4_{1} / a$ structure. Tables 7.9 and 7.10 give the departure from equivalence of the imidazole rings using the difference in degrees between the directions of the normals to the planes of the imidazoles after one of each pair of rings has been transformed by a pseudo 2-fold rotation axis parallel to $c$ so as to create pseudo superposition. The structures obtained above the transition temperature have rings $(3,7)$ and rings $(4,8)$ exactly equivalent but with a substantial libration about the relevant $M-\mathrm{N}$ bond. The entry in Table 7.10 marked (*) are obtained by evaluating $2 \sqrt{ } L_{\mathrm{ii}}$, where $L_{\mathrm{ii}}$ is the largest principal value of the libration tensor in radians ${ }^{2}$ and then converting to degrees. By comparing libration parameters above and below the transition temperatures it is reasonable to assume the libration for imidazoles $(3,7)$ does not come from a disorder.

It is to be noted that the imadazole rings have effectively no change in their pseudo equivalence except for rings 4 and 8 where the increase in libration with lowering temperature above the transition for the Mn structure (7b) is worthy of note. The amount rings have to move to invert the environment of a pseudo inversion centre is given by the values in Tables 7.7 and 7.8 implying a big change for rings 2 and 6. As can be see in Figure 7.6a, a rotation of ring 6 by about $130^{\circ}$ to take up the alternative position must involve rotating ring 8 out of the way while this ring maintains its hydrogen bond connection. Looking at 7b at 283(2) K (Table 7.8) the major libration parameter for rings $(4,8)$ is very similar to the value expected for a

1:1 disorder of the 279(2) K structure (Table 7.7). The smaller libration parameter at 295(2) K could suggest that the distribution of rings 4 and 8 is less bimodal and more gaussian, reducing the mean square displacement. This suggests that at 283(2) K reasonably sized domains are already ordered in space group $I 4_{1} / a$. The increase in the $\mathbf{c}$ axis as the temperature is lowered above the transition temperature facilitates the transition from disorder to order. It is to be noted that in $7 \mathbf{c}$, the libration of ring 8 in the 295(2) K and $180(2) \mathrm{K}$ structures is much smaller suggesting this gate is usually stuck in a near closed position. Things are only a bit better at $170(2) \mathrm{K}$, the libration increasing with the increase in the interlayer repeat. This suggests the transition temperature for $\mathbf{7 c}$ is nearer 170(2) than $180(2) \mathrm{K}$.

Table 7.7 Largest principal libration values (radians ${ }^{2}$ ) for the imidazoles of the low temperature phase $\left(I 4_{1} / a\right.$ for $\mathbf{7 b}, \mathbf{7 c}$, and $P 2 / n$ for $\left.\mathbf{7 d}\right) .{ }^{a}$

When the same approach is applied to $\mathbf{7 d}$, there is clear evidence that (see Tables 7.7 to 7.10 ) imidazoles 1 and 5 and not imidazoles 4 and 8 are associated with the phase transition that changes the hydrogen bonding of imidazoles 2 and 6 . It is reasonable to surmise that the mechanism for ordering that pushes imidazoles 4 and 8 out of the way to allow imidazoles 2 and 6 to switch hydrogen bonding arrangements has been closed down because of the smaller Ni atom, and been replaced by an alternative mechanism that involves a monoclinic distortion of the unit cell and the creation of alternate layers of different hydrogen bonding. As seen from Figure 7.10, the extra hydrogen bonds in Figure 7.10a compared to Figure 7.10b makes the $c$ axis of $16.3422(2) \AA$ longer than the $a$ axis of $16.1379(2) \AA$. The distortion is not present in the high temperature form of $7 \mathbf{d}$ and suggests that all cavities contain seven hydrogen bonded imidazoles for the $P 4_{2} / n$ structures.

## Bond lengths and angles

Bond lengths are in remarkably good agreement over the whole temperature range and are most reliable for the $100(2) \mathrm{K}$ structures in space group $I 4_{1} / a$. The $\mathrm{Mn}-\mathrm{N}$ distances range from 2.216(1) to 2.264(1) $\AA$, mean 2.253(1) $\AA$, and the $\mathrm{Mn}-\mathrm{O}$ distances range from $2.126(1)$ to $2.202(1) ~ \AA$, mean $2.154 \AA$. If the $\mathrm{Mn} 1-\mathrm{N} 21$ bond is omitted since this imidazole is disordered, then the $\mathrm{Mn}-\mathrm{N}$ range is 2.216 (1) to $2.264(1) \AA$, mean $2.251 \AA$. These are slightly longer than the bond lengths for Co and Ni, namely, $\mathrm{Co}-\mathrm{N}$ distances range from $2.109(1)$ to $2.156(1) \AA$, mean $2.137 \AA$, and the $\mathrm{Co}-\mathrm{O}$ distances range from $2.074(2)$ to $2.140(2) \AA$, mean $2.100 \AA$. If the Co1-N21 bond is omitted, then the $\mathrm{Co}^{-}-\mathrm{N}$ range is $2.057(1)$ to $2.100(1) \AA$, mean $2.076 \AA$. The $\mathrm{Ni}-\mathrm{N}$ distances range from $2.109(1)$ to $2.156(1) \AA$, mean $2.137 \AA$, and the $\mathrm{Ni}-\mathrm{O}$ distances range from $2.074(2)$ to $2.140(2) \AA$, mean $2.100 \AA$. However, it
should be noted that the imidazole not involved a hydrogen bonding always had the shortest $M-\mathrm{N}$ bond in all refinements.

The bond lengths around V fall into three groups, (i) those involving oxygens bridging ( $\mu_{2}-\mathrm{O}$ ) vanadium atoms, (ii) those involving oxygens bringing ( $\mu_{2}-\mathrm{O}$ ) a vanadium and an $M$ atom, and (iii) those involving terminal oxygens. For the Mn structure, $\mathrm{V}-\mathrm{O}$ distances (i) vary from $1.796(1)$ to $1.820(1) \AA$, mean $1.807 \AA, \mathrm{~V}-\mathrm{O}$ distances (ii) vary from 1.640 (1) to $1.651(1) \AA$, mean $1.644 \AA$, and V-O distances (iii) vary from $1.633(1)$ to $1.650(1) \AA$, mean $1.640 \AA$. For the Co structure, V-O distances (i) vary from $1.798(1)$ to $1.827(1) \AA$, mean $1.811 \AA, \mathrm{~V}-\mathrm{O}$ distances (ii) vary from $1.635(2)$ to $1.650(2) \AA$, mean $1.643 \AA$, and $\mathrm{V}-\mathrm{O}$ distances (iii) vary from 1.637 (1) to $1.653(1) \AA$, mean $1.643 \AA$. For the Ni structure, V-O distances (i) vary from $1.798(2)$ to $1.831(2) \AA$, mean $1.816 \AA, \mathrm{~V}-\mathrm{O}$ distances (ii) vary from $1.640(2)$ to 1.651(2) $\AA$, mean $1.649 \AA$, and V-O distances (iii) vary from $1.630(1)$ to $1.649(1) \AA$, mean $1.641 \AA$. The $\mathrm{O}-\mathrm{V}-\mathrm{O}$ bond angles range from $107.3(1)$ to $112.9(1)^{\circ}$, mean value $109.5^{\circ}$ for Mn , from $107.3(1)$ to $113.0(1)^{\circ}$, mean value $109.5^{\circ}$ for Co , and from 107.4(1) to $111.5(1)^{\circ}$, mean value $109.5^{\circ}$ for Ni. It is seen that the tetrahedral angles around V are corresponding to the ideal value of $109.5^{\circ}$.

### 7.3.2 Structural Description of $\left[\mathrm{Mn}(\mathrm{DMSO})(\mathrm{Im})_{3} \mathrm{~V}_{2} \mathrm{O}_{6}\right](7 \mathrm{e})$

Compound 7d crystallizes in a monoclinic system, space group $P 2_{1} / n(Z=4)$. There are two crystallographically independent V atoms and a Mn atom in the asymmetric unit, Figure 7.11. The V sites exhibit distorted tetrahedral coordination geometry with a terminal O atom (mean $\mathrm{V}=\mathrm{O}=1.631 \AA$ ) and three $\mu_{2}-\mathrm{O}$ atoms (mean $\mathrm{V}-\mathrm{O}=1.789(1) \AA$ ). The $\mathrm{V}^{5+}$ oxidation state for two unique vanadium cations is supported by valence sum calculation (Brown and Altermatt, 1985; Brese and O'Keeffe, 1991). The Mn atom is octahedrally coordinated by three N atoms from imidazole ligands (mean $\mathrm{Mn}-\mathrm{N}=2.229 \AA$ ), one O atom from DMSO solvate $(\mathrm{Mn}-\mathrm{O}$
$=2.304(1) \AA$ ), and two $\mu_{2}-\mathrm{O}$ atoms from each distorted $\left\{\mathrm{VO}_{4}\right\}$ tetrahedra (mean $\mathrm{Mn}-\mathrm{O}=2.217 \AA$ ). Selected interatomic bond lengths for compound $7 \mathbf{d}$ are given in Table 7.15.

Figure 7.11 Thermal ellipsoid plot of a fragment of $\mathbf{7 e}$ at the $30 \%$ probability level containing its asymmetric unit with atom numbering and showing coordination environments of metals centre. Hydrogen atoms are omitted for clarity. Selected bond lengths ( $\AA$ ) for 7 e : Mn1-N11 = 2.212(5), Mn1-N21 = 2.213(5), Mn1-N31 = 2.258(5), Mn1-O1 = 2.134(4), $\mathrm{Mn} 1-\mathrm{O} 2=2.118(4), \mathrm{Mn} 1-\mathrm{O} 7=2.304(4), \mathrm{V} 1-\mathrm{O} 2=$ $1.641(4), \mathrm{V} 1-\mathrm{O} 3=1.614(5), \mathrm{V} 1-\mathrm{O} 4=1.777(4), \mathrm{V} 1-\mathrm{O} 5=1.792(4)$, $\mathrm{V} 2-\mathrm{O} 1^{\mathrm{i}}=1.645(4), \mathrm{V} 2-\mathrm{O} 4^{\mathrm{ii}}=1.795(5), \mathrm{V} 1-\mathrm{O} 5=1.780(4), \mathrm{V} 1-\mathrm{O} 6=$ 1.608(5). Symmetry codes: (i) $-1 / 2+x, 1 / 2-y, 1 / 2+z$; (ii) $-x,-y, 2-z$.

The framework structure of $7 \mathbf{e}$ is constructed by $\left[\mathrm{V}_{4} \mathrm{O}_{12}\right]^{4-}$ building units covalently linked to $\mathrm{Mn}(\mathrm{Im})_{3}(\mathrm{DMSO})$ moieties through the bridging oxo groups along the crystallographic $a$ axis, Figure 7.10. The imidazole ligands and DMSO solvate decorate the layer on the periphery. The framework connectivity in $7 \mathbf{e}$ is similar to that of $\mathbf{7 b} \mathbf{- 7 d}$. However, the major difference is the replacement of one equatorial imidazole on $\mathrm{Mn}(\mathrm{II})$ with a coordinated DMSO solvent molecule resulting in the loss of $4_{2}$ symmetry lowering the symmetry to $2_{1}$. The $\left\{\mathrm{V}_{4} \mathrm{O}_{12}\right\}$ cluster of 7e exhibits approximate $C_{2 v}$ symmetry, while that in $P 4_{2} / n$ phase of $7 \mathbf{b}-7 \mathbf{d}$ is about $C_{2 h}$ symmetry.

Figure 7.12 Polyhedral representations of single layer of compound 7e, viewed along the crystallographic $a$ axis. The layer is at $z=1 / 2$.

As shown in Figure 7.13, 7e has a 2-D polymeric layer structure viewed along the crystallographic $b$ axis. The supramolecular network is formed through $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond interactions, Table 7.15, between coordinated imidazole ligands on manganese centers and bridging oxo groups or terminal vanadyl sites above and below from adjacent layers. These interactions help to stabilize the assembly as well as increase the dimensionality of the structure.

Figure 7.13 Polyhedral representations of a portion of bimetallic inorganic layers of compound 7e, viewed along the crystallographic $b$ axis.

[^7]Symmetry codes: (i) $-x-1 / 2,1 / 2+y, 3 / 2-z$; (ii) $1+x, y, z$; (iii) $1 / 2-x, 1 / 2+y, 3 / 2-z$.

### 7.4 Conclusions

In this study, five new hybrid organic-inorganic vandium oxide complexes with interesting structural motifs have been synthesized through the reactions of various stoichiometry of $\mathrm{V}_{2} \mathrm{O}_{5}, \mathrm{M}^{\mathrm{II}}(\mathrm{M}=\mathrm{Mn}, \mathrm{Co}, \mathrm{Ni})$, and the aromatic planar molecule of Im ligand under mild hydro/solvothermal conditions. The successful isolation of this species not only provides an intriguing example of hybrid organicinorganic framework materials, but also may open up possibilities for the design of new polyoxometallates (POM)-based materials and inorganic oxide microstructure as well as zeolites analog.

Compounds 7b-7e has 2-D layer structure that constructed from the basic building units of $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{MN}_{4} \mathrm{O}_{2}$ octahedra, and the Im ligand acts as a structure directing agent. An isomorphous structures of formulae $\left[M(\operatorname{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$, where $\mathrm{M}=\mathrm{Mn}(\mathbf{7 b}), \mathbf{C o}(\mathbf{7 c}), \mathbf{N i}(\mathbf{7 d})$, are particular noteworthy in displaying an interesting order-disorder crystallographic phase transition between the $P 4_{2} / n$ at 295(2) K and $I 4_{1} / a(7 \mathbf{b}$ and $7 \mathbf{c})$ or $P 2 / n(7 \mathbf{d})$ at $100(2) \mathrm{K}$. For the DMSO solvothermal synthesis of 7e, the replacement of one equatorial imidazole on $\mathrm{Mn}(\mathrm{II})$ with a covalently coordinated DMSO results in a loss of symmetry lowering the space group to $P 2_{1} / n$ at $295(2) \mathrm{K}$, but the topologically is similar to those observed in $\mathbf{7 b} \mathbf{- 7 d}$.

Remarkably, the new 3-D mixed-valence manganese metal zeolite analog 7a can be obtained from similar the building units of $\mathrm{VO}_{4}$ tetrahedra as found in those 7b-7e. Compound 7a has an anionic open 3-D inorganic framework in which the organic counterions of $[\mathrm{ImH}]^{+}$are located in 1-D tunnels generated from tenmembered rings $\left[\mathrm{Mn}_{4} \mathrm{~V}_{6}\right]$ rings, and play role as a template that provides space-filling or charge-compensation. This compound could be significant in terms of the potential
applications in acid catalysis and magnetic materials. The successful preparation of compound 7a further confirms the power of the hydrothermal reactions for isolation new metal oxide hybrids as well as the microporous solid of inorganic oxide which such solid materials may be support in the development of nanoscience and nanotechnology in the future.

## CHAPTER VIII

## CONCLUDING REMARKS

The underlying direction of the work leading to this thesis is along the lines of structure function relationships of hybrid organic-inorganic materials wherein the inorganic portion forms metal-connected networks that contain the organic moieties as templates, inclusions, or decorations. At the same time work reported herein demonstrates some common laboratory techniques and practices for single crystal growth and prediction of the arrangement of molecules or ions as they assemble in the solid metallosupramolecular structure which is a network incorporating both inorganic and organic components.

Initial synthesis of a new compound often gives an impure sample, as evidenced by color or morphology. The challenge of producing pure products of the hybrid compounds reported herein, by either bench top or hydrothermal methods, was met. Even so the precipitate sample from any one reaction mixture may still appear inhomogeneous due to mixtures of single crystals, polycrystalline powder, or amorphous material. Such mixtures may even appear to be different colors. This apparent inhomogeneity of a product can be discounted by comparing the powder Xray diffractogram from the bulk sample with the pattern calculated from the single crystal analysis. Other techniques such as elemental analyses, electron probe, thermal analysis, and spectroscopy may also used to support the structure analysis to reinforce the veracity of the correlation between structures and properties.

The first portion of this thesis provides a review on X-ray crystal structures of hybrid organic-inorganic materials that have formed in attempts to bridge different aspects of solid state supramolecular chemistry and molecular crystal engineering, and also to understand their structures-properties correlations.

Solid state phase transitions is an important subject that has been widely explored in organic crystals, and is of considerable commercial interest, particularly in the pharmaceutical industry where different polymorphic forms of drugs may have different bioavailability, and require different processing and formulation. It is also found that compounds with polymorphic forms exhibit various types of structural phase transition on external perturbations such as temperature, pressure, and/or light, which may affect the resulting physical properties. The utilization of routine analytical and spectroscopic laboratory tools for investigation of solid-state transformation is sometimes restricted. Therefore, in order to ascertain the possibility of phase transition, variable temperature X-ray diffraction, magnetic susceptibility, Mössbauer, FTIR, and thermal analysis measurements are demonstrated to be useful methods.

Specific examples of phase transition studies in this thesis are described in Chapters VI and VII. The order-disorder structural phase transition was observed in the polymeric isomorphous compounds of formula $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]_{\infty}$, where $\mathrm{M}=\mathrm{Mn}$, $\mathrm{Co}, \mathrm{Ni}, \mathrm{Im}=$ imidazole. The phase transition was studied by single crystal X-ray diffraction between 100 and 295 K . It was observed that the room temperature $P 4_{2} / n$ disordered phase is reversibly transformed to the $I 4_{1} / a$ ordered phase below 281 K for Mn and 175 K for Co . The ordered phase of Ni was found to have space group $\mathrm{P} 2 / n$ at

100 K . The phase transition mechanisms of these compounds were affected by a change of the hydrogen bond connectivity.

Another particularly interesting phase change is the magnetic spin-crossover (SCO) behavior found in the 3-D framework of formula $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]\left[\mathrm{MCl}_{4}\right]_{2}$ where $\mathrm{M}=\mathrm{Fe}^{\mathrm{III}}$ and $\mathrm{In}^{\mathrm{III}}$. The SCO transitions were characterized by use of temperature dependent magnetic susceptibility ( $2-300 \mathrm{~K}$ ) and Mössbauer effect spectral measurements (4.2, 77 and 295 K ) together with single crystal X-ray crystallography (103 and 233 K ). The data revealed that the AIBN compounds exhibit incomplete "half" SCO phenomena with no accompanying crystallographic phase change.

Taking into account for the solid state phase transition, in the cases of formal $\left[\mathrm{M}(\mathrm{Im})_{4} \mathrm{~V}_{2} \mathrm{O}_{6}\right]$ and the later $\left[\mathrm{Fe}(\mathrm{AIBN})_{3}\right]\left(\mathrm{MCl}_{4}\right)_{2}$ compounds are considered to be crystallographic first order phase transition and magnetic spin transition between two electronic states (high spin $\rightarrow$ low spin) in molecular chemistry, respectively, as evidence through careful investigation on such methods mentioned above. It is noteworthy that the phase transition should also be confirmed by differential scanning calorimetric (DSC) measurements. This will help to obtain the information required.

A number of coordination polymers and supramolecular compounds with diversified architectures and other interesting features of supramolecular interactions such as hydrogen bonds and $\pi-\pi$ stacking, network interpenetration, and molecular topology are observed in this thesis. An impressive example from the present study is the formation of the remarkable neutral hydrophilic 1-D tubular structure of the cyanide-bridged bimetallic coordination compound $\left[\mathrm{Fe}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$. This compound displays ferromagnetic behavior without any magnetic ordering in the temperature range explored (2-300 K). From the topological point of view, the $\mathrm{Mn}^{\mathrm{II}}$
ions of the 1-D tube-like structure of $\left[\mathrm{Fe}\left(2,2^{\prime}\right.\right.$-bipy $\left.)(\mathrm{CN})_{4} \mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ could possibly be replaced by other octahedral transition metal centers which would offer an opportunity to achieve multifunctional materials involving spin-crossover $\left(\left\{\mathrm{Fe}^{\mathrm{II}}(\mathrm{N})_{4}\right.\right.$ $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right\}$ centers) perhaps with porosity.

Another a beautiful example is the formation of new 3-D open-framework manganese vanadates of $[\operatorname{ImH}]\left[\mathrm{Mn}_{3}(\mathrm{OH})_{2}\left(\mathrm{~V}_{4} \mathrm{O}_{13}\right)\right]$, in which anionic oxide frameworks with ten-membered ring channels have assembled around the cationic organic guests. This compound is very interesting due to the mixed-valence $\left[\mathrm{Mn}^{\mathrm{II}}-\mathrm{Mn}^{\mathrm{III}}-\right.$ $\mathrm{Mn}^{\mathrm{II}}$ ] trimer blocks, herein observed for the first time in a manganese vanadate solid framework. These could be remarkable redox catalyst as well as promising candidates for other applications like adsorptive and ion-exchange behavior.

Since the properties of any material are largely due to its structure, control over the structure allows manipulating these properties. This thesis has demonstrated how small changes in structure (from synthetic strategy or from physical stimuli such as temperature change) lead to changes in specific target properties (i.e. magnetism or other phase). Presently, many important applications of materials chemistry can be found in the electronics, energy, medical, and processing industries. Therefore, new materials designed by chemists will certainly continue to have our impact on our economy and the world.

Hydrothermal Synthesis and Characterization of $\left(\mathrm{NH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NH}_{3}\right)^{2+}\left[(\mathrm{VO})_{2}\left(\mathrm{VO}_{4}\right)_{2}\right]^{2-}$. The $29^{\text {th }}$ Congress on Science and Technology of Thailand. 20-22 October 2003, Golden Jubilee Convention Hall, Khon Kean University, Thailand.
24. Chainok, K., Haller, K. J. Hydrothermal Synthesis and Characterization of a Micro porous Cobalt Vanadium Oxide Framework Compound. The $10^{\text {th }}$ Tri-University International Joint Seminar \& Symposium. 18-21 October 2003, Mie University, Japan.

## 2002

25. Chainok, K., Haller, K. J., Williams, I. D. Structure of the Missing $\left[\mathrm{Cu}_{2} \text { (terephthalate) }\right)_{4}$ ]"Paddle-Wheel" Coordination Polymer. The $28^{\text {th }}$ Congress on Science and Technology of Thailand. 24-26 October 2002, Queen Sirikit National Convention Center, Bangkok, Thailand.
26. Chainok, K., Haller, K. J. Molecular Structure of 2-Hydroxy-N-(2-Aminosalicylidene)Aniline. The $3^{\text {rd }}$ National Symposium on Graduate Research. 18-19 August 2002, Suranaree University of Technology, Nakhon Ratchasima, Thailand.

2001
27. Kunapongkitti, S., Chainok, K., Haller, K. J. Synthesis and Characterization of Four-Coordinate Nickel Nitrosyl Bis-Triphenyl Phosphine Halide Complexes. The $27^{\text {th }}$ Congress on Science and Technology of Thailand. 16-18 October 2001, Hadyai, Songkla, Thailand.

## CURRICULUM VITAE

## KITTIPONG CHAINOK

BORN: May 26, 1977, Nakhon Ratchasima, Thailand

## EDUCATION

Sep 2004 - Dec 2008 Ph.D. in Chemistry, Suranaree University of Technology Jul 2001 - Aug 2004 M.Sc. in Chemistry, Suranaree University of Technology Jul 1996 - Sep $2000 \quad$ B.Sc. in Chemistry, Ramkhamhaeng University

## PROFESSIONAL EXPERIENCE

Oct 2007 - Jul 2008 Visiting Scholar, Monash University
Apr 2007 - Aug 2008 Visiting Scholar, ANU
Sep 2006 - Mar 2007 Visiting Scholar, Monash University
Jul - Aug 2006 Summer School on Porous Materials, UCSB
May - Jun $2006 \quad$ Visiting Research, HKUST

## SCHOLARSHIPS, HONORS, AND AWARDS

2009 PACCON Outstanding Oral Presentation Award; 2008, 2005, 2004 IUCr Young Scientist Travel Grant; 2007 Endeavour Research Fellowship; 2006 ICMR Summer School Grant; 2006 Endeavour Asia Award; 2006 SUT Outstanding Research Award; 2004 IUCr Outstanding Presentation Award; 2003 SUT \& Mie Univ. Travel Grant; 2002 SUT Research Grant for Master Degree Study

## PROFESSIONAL AFFILIATIONS AND ACTIVITIES

Member of the Chemistry Society of Thailand, Member of the American Crystallographic Association (ACA), Member of the Society of Crystallographers in Australia and New Zealand (SCANZ), Captain of SUT Football Team (2003-2004)

[^0]:    Computer programs: Crystal Maker (2006), Diamond v. 3e (Brandenburg and Putz, 2006), SADABS (Blessing, 1995), SHELXL-97 (Sheldrick, 1997), SHELXS-97 (Sheldrick, 1997), and X-SEED (Barbour, 2001).

[^1]:    ${ }^{a}$ Estimated standard deviations of the least significant digits are given in parentheses.

[^2]:    Computer programs: Crystal Maker (2006), Diamond v. 3e (Brandenburg and Putz, 2006), SADABS (Blessing, 1995), SHELXL-97 (Sheldrick, 1997), SHELXS-97 (Sheldrick, 1997),

[^3]:    ${ }^{[a]}$ Isomer shift data are reported with respect to iron foil.

[^4]:    Computer programs: COLLECT (Nonius BV, 1997-2000), HKL SCALEPACK (Otwinowski and Minor, 1997), DENZO and SCALEPAK (Otwinowski and Minor, 1997), SIR97

[^5]:    ${ }^{a}$ Estimated standard deviations are given in parentheses.

[^6]:    ${ }^{a}$ Estimated standard deviations are given in parentheses.

[^7]:    ${ }^{a}$ Estimated standard deviations are given in parentheses.
