อรรถัย สายสะอาด : สังเคราะห์และวิเคราะห์เอกลักษณ์ของอะพาไทต์และวัฏภาคอื่นจากสารละลายแคลเซียม-เลด-ฟอสเฟต (SYNTHESIS AND CHARACTERIZATION OF APATITE AND OTHER PHASES FROM CALCIUM-LEAD-PHOSPHATE SOLUTIONS) อาจารย์ที่ปรึกษา : รองศาสตราจารย์ ดร.เค็นเนท เจ. แสเลออร์, 130 หน้า.

งานวิจัยนี้ศึกษาอะพาไทต์และสารที่เกี่ยวข้องประกอบด้วยแคลเซียมไฮดรอกซีอะพาไทต์ (CaHAp) เลดไฮดรอกซีอะพาไทต์ (PbHAp) และสารแคลเซียม-ฟอสเฟต สารเลด-ฟอสเฟตอื่น และสารแคลเซียม-เลด-ฟอสเฟต ผลจากการวิเคราะห์โครงสร้างของ PbHAp (โครงสร้างที่ตีพิมพ์แล้วจากข้อมูลที่ได้จาก powder X-ray diffraction) พบว่ามีความคลาดเคลื่อนของค่าผลรวม bond valence จากค่าที่น่าจะเป็นของอะตอม P Pb(2) และ O(4) ในโครงสร้างของ PbHAp ซึ่งค่าของผลรวม bond valence ในโครงสร้างที่ตีพิมพ์แล้วดีขึ้นหลังจากการปรับอะตอม O(3) และ O(4) แต่ค่าที่ได้ยังไม่ดีที่สุด จากผลที่ได้นี้สามารถชี้ได้ว่าแบบโครงสร้างของ PbHAp ที่ตีพิมพ์แล้วนี้อาจจะมีความผิดพลาด

วิธีการตกผลึกด้วยเจล และวิธีรีฟลักซ์ ถูกใช้เพื่อเตรียม PbHAp ให้มีผลึกที่ใหญ่ขึ้น สารผลิตภัณฑ์ที่ได้จากวิธีการตกผลึกด้วยเจลระบุได้ว่ามีวัฏภาคของ  $PbHPO_4$   $Pb_3(PO_4)_2$  และ PbHAp ซึ่งงานนี้เป็นงานแรกที่สามารถเตรียม PbHAp การปรับปรุงการทดลองโดยเพิ่มชั้นของเจลบริสุทธิ์ อาจจะเป็นปัจจัยสำคัญที่ทำให้ได้ PbHAp ผลของ XRD SEM และโปรแกรม PHREEQC แสดงให้เห็นว่ามีสารผลิตภัณฑ์หลายชนิดในระบบนี้ การปรากฏ PbHAp ในชั้นของเจลบริสุทธิ์แต่ไม่พบในชั้นของเจลฟอสเฟตอาจจะเนื่องมาจากการเกิด PbHAp ต้องการอัตราส่วนของ  $Pb^{2+}:PO_4^{3-}$  สูงกว่าการเกิด  $Pb_3(PO_4)_2$  (5:3 ต่อ 3:2) และผลจากการเพิ่มขึ้นของจำนวนไอออน  $PO_4^{3-}$  ใกล้เคียงกับชั้นของสารละลายเลดหลังจากการเพิ่มสารละลายเจลบริสุทธิ์ลงบนชั้นของเจลฟอสเฟต ค่า pH ของระบบนี้ลดลงเนื่องมาจากการปรับสมดุลของไอออนเพื่อเปลี่ยน  $HPO_4^{2-}$  ไปเป็น  $H^+$  และ  $PO_4^{3-}$  เมื่อเกิดการตกตะกอนของสารที่มี  $PO_4^{3-}$  เป็นองค์ประกอบ

วิธีรีฟลักซ์ ถูกนำมาใช้เพื่อเพิ่มอัตราการละลายของ CaHAp และอัตราการตกผลึกของ PbHAp ในระบบ ซึ่งผลที่ได้แสดงให้เห็นว่าขนาดผลึกของสารผลิตภัณฑ์เพิ่มขึ้นเมื่อเพิ่มระยะเวลาการทำปฏิกิริยา ผลึกขนาดใหญ่ที่สุดที่เตรียมได้มีขนาดใหญ่กว่าผลึกที่ได้จากงานตีพิมพ์อื่นซึ่งมีวิธีการเตรียมใกล้เคียงกัน (วิธีการเขย่าเชิงกล) และมีขนาดใหญ่กว่าผลึกที่ได้จากวิธีการตกผลึกด้วยเจล ผลของ XRD และ EDX ยืนยันได้ว่าสารผลิตภัณฑ์ที่เป็นของแข็งนี้คือ สารอะพาไทต์และแสดงถึงการผสมกันของวัฏภาค CaHAp และ PbHAp เนื่องจากความลำบากในการแยกสารผลิตภัณฑ์ PbHAp จากสารตั้งต้น

สารละลายของแข็งแคลเซียม-เลดไฮดรอกซีอะพาไทต์ (Ca-PbHAp) ได้ถูกเตรียมขึ้นจากวิธีการตกตะกอนและผลของ XRD ซึ่งให้เห็นว่ามี วัฏภาคของ CaHAp และ PbHAp เกิดขึ้น แต่ Ca-PbHAp ไม่เกิดในระบบนี้ ผลที่ได้นี้สอดคล้องกับการที่ไม่ปรากฏพฤติกรรมของสารละลายของแข็งตามกฎของ Vegard ผลจากการคำนวณโดยโปรแกรม PHREEQC ซึ่งให้เห็นว่ามีวัฏภาคหลายชนิดของ แคลเซียม-ฟอสเฟต และ เลด-ฟอสเฟต อิ่มตัวยิ่งยวดในระบบ ซึ่งแสดงว่ามีสารผลิตภัณฑ์หลายตัวสามารถเกิดได้ในระบบนี้ อย่างไรก็ตาม สารเหล่านี้ไม่สามารถแสดงพีคที่ชัดเจนได้ใน XRD เนื่องจากเป็นสารผลิตภัณฑ์ส่วนน้อย

Ph.D. 130 PP.

CALCIUM-PHOSPHATE/LEAD-PHOSPHATE/CALCIUM-LEAD-PHOSPHATE/  
CALCIUM HYDROXYAPATITE/LEAD HYDROXYAPATITE/APATITE

Apatite and related materials including calcium hydroxyapatite (CaHAp), lead hydroxyapatite (PbHAp), and other calcium-phosphate, lead-phosphate, and calcium-lead-phosphate materials were studied in this work. Results from the structural analysis of PbHAp (published structure based on powder X-ray diffraction data) demonstrate discrepancy in the expected bond valence sum values of P, Pb(2), and O(4) atoms in the PbHAp structure. Modification of the O(3) and O(4) positions improve the bond valence sums of the published structure but they are still not optimal. These results suggest that there is probable error in the published PbHAp structure model.

Gel crystallization and reflux methods were utilized for preparation of larger PbHAp crystals.  $\text{PbHPO}_4$ ,  $\text{Pb}_3(\text{PO}_4)_2$ , and PbHAp phases are identified in the gel crystallization product. The presence of PbHAp from this method is first reported in this work. The experimental modification of adding a pure gel layer may be an important factor for obtaining PbHAp material. XRD, SEM, and PHREEQC results show multiple product phases in the system, but the presence of PbHAp in the pure gel layer and not in the  $\text{PO}_4^{3-}$  gel layer may be attributed to the higher  $\text{Pb}^{2+}:\text{PO}_4^{3-}$

ratio (5:3 vs 3:2) required for the PbHAp phase relative to the  $\text{Pb}_3(\text{PO}_4)_2$  phase and the increment of  $\text{PO}_4^{3-}$  ion concentrations near the lead solution after placing the pure gel solution on the  $\text{PO}_4^{3-}$  gel layer. The pH of the system decreases as crystallization occurs due to the speciation equilibrium converting  $\text{HPO}_4^{2-}$  to  $\text{H}^+$  and  $\text{PO}_4^{3-}$  as  $\text{PO}_4^{3-}$  containing species precipitate.

Reflux method was used to increase CaHAp dissolution rate and consequently PbHAp crystallization rate in the system and results show product crystal size increased with increasing reaction time. The largest crystal size from this work is larger than has been reported in previous work with similar methodology. XRD and EDX results confirm solid products are apatite materials and show mixed phases of CaHAp and PbHAp due to the difficulty in separation of the PbHAp product from the reaction substrate. Larger PbHAp crystals were obtained from the reflux method than from the gel crystallization method.

Calcium-lead hydroxyapatite solid solution (Ca-PbHAp) materials were prepared by a precipitation method. XRD results suggest the CaHAp and PbHAp phases are formed but Ca-PbHAp is not formed in this system. These results are consistent with the absence of Vegard's law behavior. PHREEQC calculations show several calcium-phosphate and lead-phosphate phases are supersaturated, suggesting multiple products can be formed in this system. However, these phases do not appear clearly in the XRD pattern because they are minor products.

## ACKNOWLEDGEMENTS

I would like to express sincere thanks to my thesis advisor, Assoc. Prof. Dr. Kenneth J. Haller, for his kindness and patience to me during my study at SUT. I am very appreciative for his advice and help about studying, thinking, and solving problems when I was getting stuck with problems. He treated me as stronger and more responsible. Because of his advice, help, and force, I could be successful in my study and have beneficial personal growth, thank you very much.

I would like to thank the Commission on Higher Education (CHE), Thailand for the financial support of my Ph.D. study and research.

I would like to thank Prof. Dr. Adrian E. Flood, Asst. Prof. Dr. Sutham Srilomsak, and Dr. Weenawan Somphon for participating in my Ph.D. thesis committee. I am grateful for their comments and suggestions.

I wish to express my special thanks to Asst. Prof. Dr. Kunwadee Rangriwatananon for serving as the chairperson of my committee, for lectures at the School of Chemistry, and for her suggestions. Special thanks also to Assoc. Prof. Dr. Malee Tangsathitkulchai for her warm hearted support, encouragement, and help.

Special thanks to past and current members of the Crystallography and Applied Surface Science Research Group, Suranaree University of Technology for their helpfulness, advice, mental support, wonderful friendships, sharing knowledge, and social activities during my study at SUT.

Finally, I would like to express my thankfulness to my parents, my brother, and my sister for every support throughout the long time of my study, and without whose love and understanding this work would not have been possible.

# CHAPTER I

## INTRODUCTION

### 1.1 Lead

Lead is a toxic heavy metal which can be released into the environment and contaminate the human food chain. The U.S. Centers for Disease Control and Prevention (CDC) currently designates a blood-lead level of 10  $\mu\text{g/dL}$  (0.48  $\mu\text{mol/L}$ ) or higher as abnormal and requiring follow-up and intervention (Centers for Disease Control and Prevention, 2012). Blood-lead levels lower than 10  $\mu\text{g/dL}$  can also affect cognitive development (Needleman, Schell, Bellinger, Leviton, and Allred, 1990). The Ministry of Public Health of Thailand designated the standard blood-lead level of 40  $\mu\text{g/dL}$  (Ministry of Public Health of Thailand, 2001).

#### *Lead source*

In the past lead was used in several industries such as paint, gasoline, pipe, and solder. Because lead is responsible for potential health problems, the amount of lead used in paint, gasoline, pipe, and solder has been reduced in recent years. However, lead is still used in many industries, including construction, mining, burning fossil fuels, and manufacturing. Lead is often used to make batteries and other metal products and also used in the production of pottery and ceramics.

The source of lead exposure is ingestion of contaminated food and drinking water. Sources of lead contaminated drinking water are untreated natural drinking water from ground water or surface water and drinking water from lead-soldered

joints or leaded pipes in water distribution systems or individual houses. Lead may also enter foods if they are put into improperly glazed pottery or ceramic dishes.

Another potential source of exposure is occupation. Potentially high levels of lead may occur in the following industries: lead smelting and refining industries, battery manufacturing plants, steel welding or cutting operations, construction, rubber products and plastics industries, printing industry, firing ranges, radiator repair shops, and other industries requiring flame soldering of lead solder.

In the U.S. the standard for airborne lead in the workplace is set at less than  $100 \mu\text{g}/\text{m}^3$  by the National Institute for Occupational Safety and Health, NIOSH (2003). In Thailand the standard for airborne lead in the workplace set by the Ministry of Interior of Thailand (Ministry of Interior of Thailand, 1972) is  $200 \mu\text{g}/\text{m}^3$  which is higher than the U.S.

The lead levels in normal human and environmental samples in the U.S. and Thailand are listed in Tables 1.1 and 1.2, respectively.

**Table 1.1** Lead standards for biological systems and the environment in the U.S.

Occurrence	Lead level	Reference
<b>Lead in biological system</b>		
- Blood ( $\mu\text{g}/\text{dL}$ )	10	Centers for Disease Control and Prevention, 2012
<b>Lead in environment</b>

### ***Health effects of lead exposure***

Humans are at risk of being exposed to lead, by breathing it in, ingesting it, or coming in contact with it. Lead accumulated by humans over time is deposited in bone, a long term storage site for lead, with a half-life of about 20 years (Rabinowitz, Wetherill, and Kopple, 1976). Lead can affect almost every organ and system in the human body, especially the nervous system, of both adults and children. Lead may causes weakness in fingers, wrists, and ankles. It also may cause small increases in blood pressure, particularly in middle-aged and older people and decreased heme biosynthesis, elevated hearing threshold, and depressed serum levels of vitamin D (Warniment, 2010). Exposure to high lead levels can damage the brain and kidneys and ultimately cause death as reported by the Agency for Toxic Substances and Disease Registry, ASTDR (2007). Long-term exposure to lead decreased performance in some tests. High bone-lead levels indicate long-term exposure and are related to bone diseases like osteoporosis. There are several reports on the effects of lead on bone formation such as reduction of bone formation activity in dogs with blood-lead levels between 50 and 80  $\mu\text{g}/\text{dL}$  (Anderson and Danylchuk, 1977), in rabbits with high dose lead exposure (Hass, Landerholm, and Hemmens, 1967), and in Egyptian vultures with bone-lead levels more than 20  $\mu\text{g}/\text{g}$  (Gangoso *et al.*, 2009). Blood-lead and bone-lead concentrations corresponding to human health effects are summarized in Table 1.3 (Agency for Toxic Substances and Disease Registry, 2007).

**Table 1.3** Blood-lead and bone-lead concentrations corresponding to human health effects.

Age	Effect	Blood-lead levels ( $\mu\text{g/dL}$ )	Bone-lead levels (g/g)
Children	Depressed ALAD	$< 5^1$	ND
Children	Neurodevelopmental effects	$< 10^1$	ND
Children	Sexual maturation	$< 10^1$	ND
Children	Depressed vitamin D	$> 15$	ND
Children	Elevated EP	$> 15$	ND
Children	Depressed NCV	$> 30$	ND
Children	Depressed hemoglobin	$> 40$	ND
Children	Colic	$> 60$	ND
Adults (elderly)	Neurobehavioral effects	$> 4$	$> 30$
Adults	Depressed ALAD	$< 5^1$	ND
Adults	Depressed GFR	$< 10^1$	$> 10$
Adults	Elevated blood pressure	$< 10^1$	$> 10$
Adults	Elevated EP (females)	$> 20$	ND
Adults	Enzymuria/proteinuria	$> 30$	ND
Adults	Peripheral neuropathy	$> 40$	ND
Adults	Neurobehavioral effects	$> 40$	ND
Adults	Altered thyroid hormone	$> 40$	ND
Adults	Reduced fertility	$> 40$	ND
Adults	Depressed hemoglobin	$> 50$	ND

ALAD =  $\delta$ -aminolevulinic acid dehydrate; EP = erythrocyte protoporphyrin; GFR = glomerular filtration rate; NCV = nerve conduction velocity; ND = no data

<sup>1</sup>Some subjects can be affected at this level. An absolutely safe level is not known.

### ***Lead poisoning in Thailand***

The World Health Organization (WHO) has reported lead contamination of resources in Thailand (World Health Organization, 2008). Sources of lead contamination are generated from human activities such as mining and industry, and

may contribute to ingested lead in normal human life activities such as drinking tap water. Industries release lead waste contamination to the environment from industrial production processes, such as metal mixture, bullet, and X-ray protection building (World Health Organization, 2008). Lead waste from industries may contaminate the environment and food chain resulting in lead exposure in human.

Lead contamination of surface water in Thailand is found in mining and industrial areas such as Bannang Sata district in Yala province, Pattani River in Pattani province, and Thong Pha Phum district in Kanchanaburi province. The largest manmade contamination is from lead mining in Thong Pha Phum district, Sangkla Buri district, and Si Sawat district in Kanchanaburi province. Klity stream is a large stream in Kanchanaburi province which is near the lead mining in Thong Pha Phum district, Sangkla Buri district, and Si Sawat district (World Health Organization, 2008).

In 1998 people are in trouble with the consumption of water taken from Klity stream. The pollution control department has been monitoring lead contamination of the 8-kilometer-long Klity stream by sampling water, sediment, and aquatic animals. Results show lead contamination of surface waters are in the range of 17-40  $\mu\text{g}/\text{dL}$ , much higher than the Thai standard of 5  $\mu\text{g}/\text{dL}$ . Lead levels in sediments are in the range of 38.9-65.8  $\mu\text{g}/\text{g}$ , 20-100 times higher than the area without mining. Lead levels in fish are ten times higher than the allowable food standard of 1  $\mu\text{g}/\text{g}$  (Ministry of Public Health of Thailand, 1986). Therefore, aquatic animals, such as fish, shrimp, shell, and crab in Klity stream are not suitable for consumption (World Health Organization, 2008).

Several central and local departments of the Ministry of Public Health (Department of Health, Department of Medical Services, Division of Epidemiology, and Provincial Health Office) have set up mobile units to investigate and study the health impacts on villagers who live downstream in Klity Lang Village where the highest lead contamination levels were found. In the preliminary study the blood-lead level from 3 groups of villagers, young children (0-6 years), schoolchildren (7-15 years), and teenagers and adults ( $\geq 16$  years) were in the range of 10-44  $\mu\text{g}/\text{dL}$ , 21-33  $\mu\text{g}/\text{dL}$ , and 9-41  $\mu\text{g}/\text{dL}$ , respectively. For young children and schoolchildren, almost all blood-lead levels were higher than the CDC standard of 10  $\mu\text{g}/\text{dL}$ . In adults, there were 3 people with blood-lead levels higher than 40  $\mu\text{g}/\text{dL}$ .

The U.S. CDC informs the Ministry of Public Health, Thailand that up to 13 % of Burmese refugee children who were transferred to the U.S. during 2007-2009 have elevated blood-lead levels, EBLL, (blood lead level  $> 10 \mu\text{g}/\text{dL}$ ). Most of them lived in Umphang district, Tak province. A study on 213 3-7 year old Thai children with average age of  $54.54 \pm 12.41$  months indicates an average blood-lead level of  $7.71 \pm 4.62 \mu\text{g}/\text{dL}$  (range = 3-25  $\mu\text{g}/\text{dL}$ ). Fifty-seven of these Thai children (26 %) had blood-lead level at 10  $\mu\text{g}/\text{dL}$  or more. Analysis controlling other factors, indicates only gender and source of drinking water are risk factors. Specially, male children have 2.8 times higher risk than female children. Children who drink tap water and canal water have 15 and 72 times higher risk, respectively, than children drinking bottle water. Tap water in this area comes directly from natural waters in the mountains via pipes with no standard process performed for converting the natural water to drinking water. The results of this study show 1 of 4 Thai children in

Umphang district, Tak province who live near the Burmese refugee camps have EBLL (Neesanan *et al.*, 2011).

A study on 296 children with an average age  $1.66 \pm 1.39$  years old in four communities, 2 in Bangkok (Klong Toei and Siriraj) and 2 in Kanchanaburi province (Thong Pha Phum and Paholpolpayuhasena) shows 8.1% of children with EBLL. The risk factors for EBLL were the presence of peeling paint inside or outside the house, eating paint chips, and the geographic location of children. Again, the results indicate that the source of drinking water is a risk factor which has an impact on EBLL (Chomchai, Padungtod, and Chomchai, 2005).

A study on 245-282 workers in a battery manufacturing plant in Bangkok, Thailand during 1998-2002 indicates the workers were exposed to lead in sections such as casting, spreading, forming, polishing, assembly, and special battery production. Workers have geometric average of blood-lead level increased from 17.9  $\mu\text{g/dL}$  to 22.3  $\mu\text{g/dL}$  during 4 years but no workers had blood-lead level 60  $\mu\text{g/dL}$  or more in 2002. Factors of sex, age, and duration of work were considered in this work. The results found average blood-lead level in males of 23.3  $\mu\text{g/dL}$  and in females of 12.6  $\mu\text{g/dL}$ . However, age and duration of work did not have significant effect on the average blood-lead level of workers. The correlation between blood-lead level and airborne lead level was also studied. High airborne lead level was detected in all sections, especially, in the forming and polishing sections. These sections had airborne lead levels higher than the standard level set by the Ministry of Interior of Thailand (200  $\mu\text{g/m}^3$ ). However, this study did not find airborne lead level to have a significant effect on average blood-lead level of workers (Lormphongs *et al.*, 2003).

A further study of lead poisoning on 132 workers at the assembly section in the same battery manufacturing plant in Bangkok, Thailand in 2002 shows a high average blood-lead level of 32.7  $\mu\text{g/dL}$ . After occupational health education and training to workers and managers, the average blood-lead level was reduced to 22.4  $\mu\text{g/dL}$ , although the airborne lead level in the workplace remained unchanged from previous values. Airborne lead level in the workplace was between 0.026-0.603  $\text{mg/m}^3$ , eight samples (36.3 %) were more than the standard level of 200  $\mu\text{g/m}^3$  set by the Ministry of Interior of Thailand (Lormphongs *et al.*, 2004).

## 1.2 Apatite materials

Apatite is the name of a mineral supergroup. The chemical formula of apatite is  $\text{M}(1)_2\text{M}(2)_3(\text{TO}_4)_3\text{X}$ . M(1) and M(2) are monovalent, divalent, and trivalent cations, such as  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Pb}^{2+}$ ,  $\text{Al}^{3+}$ ,  $\text{Bi}^{3+}$ ,  $\text{Y}^{3+}$ , or  $\text{La}^{3+}$ ;  $\text{TO}_4$  is a divalent, trivalent, or tetravalent anion, such as  $\text{SO}_4^{2-}$ ,  $\text{PO}_4^{3-}$ ,  $\text{VO}_4^{3-}$ ,  $\text{AsO}_4^{3-}$ , or  $\text{SiO}_4^{4-}$ ; and X is a monovalent anion, such as  $\text{OH}^-$ ,  $\text{F}^-$ , or  $\text{Cl}^-$ . Other anions, including  $\text{CO}_3^{2-}$  and  $\text{NO}_3^-$  may also occur in the  $\text{TO}_4$  sites.

### *Classes of apatite materials*

The apatite supergroup can be divided into five groups, based on crystal-chemical arguments (Pasero *et al.*, 2010);

*Apatite group*: hexagonal and pseudo-hexagonal phosphates, arsenates, and vanadates containing the same cation at both the M(1) and M(2) sites, such as  $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$ ,  $\text{Ca}_5(\text{PO}_4)_3\text{F}$ ,  $\text{Pb}_5(\text{PO}_4)_3\text{Cl}$ ,  $\text{Ba}_5(\text{PO}_4)_3\text{Cl}$ , or  $\text{Pb}_5(\text{PO}_4)_3(\text{OH})$ .

*Hedyphane group*: hexagonal and pseudo-hexagonal phosphates, arsenates, and sulfates containing different cations at the M(1) and M(2) sites, such as  $\text{Ca}_2\text{Pb}_3(\text{AsO}_4)_3\text{Cl}$ ,  $\text{Ca}_2\text{Pb}_3(\text{AsO}_4)_3\text{OH}$ ,  $\text{Ca}_2\text{Sr}_3(\text{PO}_4)_3\text{F}$ , or  $\text{Mn}_2\text{Ca}_3(\text{PO}_4)_3\text{Cl}$ .

*Belovite group*: hexagonal and trigonal phosphates with the M(1) site split into M(1) and M(1') sites containing different cations, such as  $\text{SrCaCa}_3(\text{PO}_4)_3\text{F}$ ,  $\text{NaCeSr}_3(\text{PO}_4)_3\text{F}$ , or  $\text{NaCeBa}_3(\text{PO}_4)_3\text{F}_{0.5}\text{Cl}_{0.5}$ .

*Britholite group*: hexagonal and pseudo-hexagonal silicates, typically with partially ordered M(1) and M(2) cations, such as  $(\text{Ce,Ca})_5(\text{SiO}_4)_3(\text{OH})$ ,  $(\text{Y,Ca})_5(\text{SiO}_4)_3(\text{OH})$ , or  $(\text{Y,Ca})_5(\text{SiO}_4)_3\text{F}$ .

*Ellestadite group*: hexagonal and pseudo-hexagonal sulfato-silicates with the ideal ratio for charge balance of  $(\text{SiO}_4)^{4-}:(\text{SO}_4)^{2-}$  1:1, such as  $\text{Ca}_5(\text{SiO}_4)_{1.5}(\text{SO}_4)_{1.5}(\text{OH})$ ,  $\text{Pb}_5(\text{SiO}_4)_{1.5}(\text{SO}_4)_{1.5}\text{Cl}$ , or  $\text{Pb}_5(\text{SiO}_4)_{1.5}(\text{SO}_4)_{1.5}(\text{OH})$ .

### ***Characteristics of apatite materials***

One interesting characteristic of apatites is their susceptibility to ionic substitution in both anionic and cationic sites. Divalent cations with ionic radii about 1 Å can form apatites such as  $\text{Ca}^{2+}$ ,  $\text{Ba}^{2+}$ ,  $\text{Cd}^{2+}$ , and  $\text{Pb}^{2+}$ , with free ionic radii 0.99, 1.13, 0.97, and 1.35 Å, respectively (Narasaraju and Phebe, 1996). It should be noted that the ionic radii in bound states is larger than the free ion radii and depends on the coordination number of the ion. For example, with coordination number 7,  $\text{Ca}^{2+} = 1.20$  Å and  $\text{Pb}^{2+} = 1.37$  Å, and with coordination number 9,  $\text{Ca}^{2+} = 1.32$  Å and  $\text{Pb}^{2+} = 1.49$  Å (Bruckner, Lusvardi, Menabue, and Saladini, 1995). Among the anionic substituents, the monovalent anions ( $\text{OH}^-$ ) can be replaced by  $\text{F}^-$ ,  $\text{Cl}^-$ , and a variety of other monovalent anions, while trivalent anions ( $\text{PO}_4^{3-}$ ) can be replaced by  $\text{AsO}_4^{3-}$

and  $\text{VO}_4^{3-}$ , the anionic radii of these being 1.68, 1.32, and 1.81, and 1.10, 1.18, and 1.22 Å, respectively (Narasaraju and Phebe, 1996). All structures within the apatite group are isostructural. However, there are two series within the group, the apatite series and the pyromorphite series. Pyromorphite is lead chlorophosphate,  $\text{Pb}_5(\text{PO}_4)_3\text{Cl}$ , and the principal cation in the pyromorphite series is lead. Examples of apatites and pyromorphites, their empirical formula, and their lattice constants are given in Table 1.4.

**Table 1.4** Name, formula, and lattice constants of selected apatites.

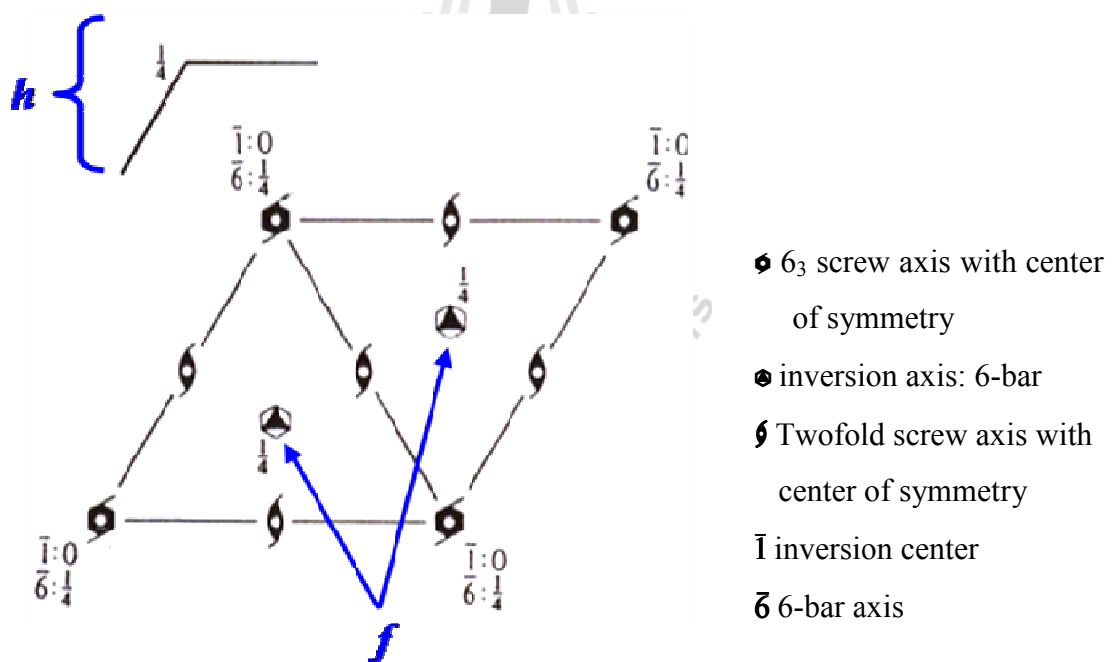

Series	Name	Empirical formula	Lattice constants (Å)	
			<i>a</i>	<i>c</i>
Apatite	Barium hydroxyapatite	$\text{Ba}_5(\text{PO}_4)_3(\text{OH})$	10.19	7.70
	Cadmium arsenic chloroapatite	$\text{Cd}_5(\text{AsO}_4)_3\text{Cl}$	10.07	7.26
	Cadmium hydroxyapatite	$\text{Cd}_5(\text{PO}_4)_3(\text{OH})$	9.01	6.61
	Cadmium chloroapatite	$\text{Cd}_5(\text{PO}_4)_3\text{Cl}$	9.62	6.49
	Calcium hydroxyapatite	$\text{Ca}_5(\text{PO}_4)_3(\text{OH})$	9.42	6.88
	Chlorapatite	$\text{Ca}_5(\text{PO}_4)_3\text{Cl}$	9.63	6.78
	Fermorite	$\text{Ca}_5(\text{AsO}_4)_6\text{F}$	9.75	6.92
	Fluorapatite	$\text{Ca}_5(\text{PO}_4)_3\text{F}$	9.35	6.58
	Hydroxyvanadinite	$\text{Ca}_5(\text{VO}_4)_3(\text{OH})$	9.82	6.98
	Lead hydroxyapatite	$\text{Pb}_5(\text{PO}_4)_3(\text{OH})$	9.90	7.29
	Magnesium hydroxyapatite	$\text{Mg}_5(\text{PO}_4)_3(\text{OH})$	9.30	6.89
	Strontium hydroxyapatite	$\text{Sr}_5(\text{PO}_4)_3(\text{OH})$	9.76	7.28
	Pyromorphite	Pyromorphite	$\text{Pb}_5(\text{PO}_4)_3\text{Cl}$	9.95
Vanadinite		$\text{Pb}_5(\text{VO}_4)_3\text{Cl}$	10.47	7.43
Mimetite		$\text{Pb}_5(\text{AsO}_4)_3\text{Cl}$	10.36	7.52

A distinguishing characteristic of the two series is that, while members within one series can readily form solid solutions with other members of the same series,

they in general do not easily form solid solutions with members of the other series (Berry and Mason, 1959).

### *Structural aspects of apatites*

Apatite structures belong to space group  $P6_3/m$  with the general formula  $M(1)_2M(2)_3(TO_4)_3X$ . Figure 1.1 shows a representation of the symmetry properties of space group  $P6_3/m$ . The Wyckoff special positions<sup>1</sup> relevant to apatite structure are indicated on the diagram. The  $f$  positions are on 3-fold rotation axes at  $1/3, 2/3, z$  and  $2/3, 1/3, z$  and the  $h$  positions are on mirror planes at  $z = 1/4$  and  $z = 3/4$ .

**Figure 1.1** Representation of the symmetry properties of space group  $P6_3/m$  projected on the  $ab$  plane. Wyckoff positions,  $f$  and  $h$ , relevant to apatite structure are indicated on the diagram (Hahn, 1996).

<sup>1</sup> Wyckoff positions are represented by letters, starting with  $a$  for the most symmetric special position in the space group under consideration, and continuing in alphabetical order until the general position is reached.

The CaHAp structure (Figure 1.2) consists of five  $\text{Ca}^{2+}$  ions, three  $\text{PO}_4^{3-}$  ions, and one  $\text{OH}^-$  ion. Two  $\text{Ca}^{2+}$  ions in the M(1) positions are located on  $f$  sites with 3 symmetry. Three  $\text{Ca}^{2+}$  ions in the M(2) positions, three P atoms, and six phosphate O atoms are located on  $h$  sites with  $m$  symmetry. The other six phosphate O atoms are located on general positions, pairwise related by the mirror plane through the P atoms. The hydroxyl O is disordered along the 3 axis near the 6-bar site with the hydrogen atom further disordered about the 3 axis.

**Figure 1.2** Representation of Ca, O, and P atoms in apatite structures projected on the  $ab$  plane. The polyhedra represent phosphate groups in the structure.

The  $\text{Ca}^{2+}$  ions at the  $f$  sites are coordinated with nine O atoms (six shorter bonds define a twisted trigonal prism and the three longer bonds extend through the prism faces). The  $\text{Ca}^{2+}$  ions at the  $h$  sites are coordinated with seven O atoms; six O atoms from  $\text{PO}_4^{3-}$  groups and one O atom from the  $\text{OH}^-$  group. The  $\text{PO}_4^{3-}$  groups project as

pairs of triangles about the  $2_1$  axes in Figure 1.2. The  $\text{OH}^-$  ions are disordered along the 3 axis. The coordination environments of the distinct  $f$  and  $h$   $\text{Ca}^{2+}$  sites are different, consequently the ionic size of  $\text{Ca}^{2+}$  in these two positions are different. Thus, the ability to substitute other cations for  $\text{Ca}^{2+}$  at the two positions should also be different.

### ***Applications of apatite materials***

Apatites have been studied in several applications including as material for removal and immobilization of heavy metals from contaminated water (Admassu and Breese, 1999; Smičiklas, Onjia, Raičević, Janacković, and Mitrić, 2008), as support material for catalyst reactions (Mori *et al.*, 2002; Mori, Hara, Mizugaki, Ebitani, and Kaneda, 2003), and as biomaterial for artificial bones and teeth (Walsh and Tanaka, 2001).

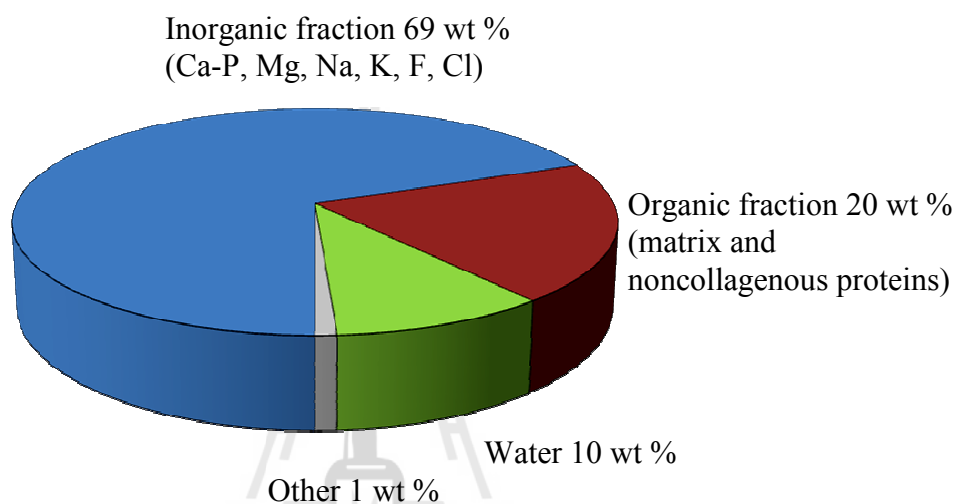

### **1.3 Calcium-phosphate in mammalian hard tissues**

Mammalian hard tissues such as teeth and bones are composed primarily of calcium-phosphates (Ca-P), including calcium hydroxyapatite (CaHAp) and other calcium-phosphate materials such as calcium hydrogen phosphate dihydrate (CHPD), calcium hydrogen phosphate (CHP), octacalcium phosphate (OCP), and calcium phosphate (CP). Natural teeth consist of three parts; enamel, dentine, and cementum with weight percents of CaHAp of 95, 75, and 35, respectively (Narasaraju and Phebe, 1996). There are two main parts of bone; inorganic (69 wt %) and organic (20 wt %) parts (Shi, 2005). The inorganic part contains calcium-phosphate, magnesium,

sodium, potassium, fluoride, and chloride while the organic part contains primarily matrix proteins (mostly collagen) and noncollagenous proteins (*i.e.* proteoglycans).

Bone also contains water (10 wt %) and other components such as polysaccharides and lipids in small quantities as shown in Figure 1.3.

**Figure 1.3** Composition of bone (LeGeros, 1991).

### ***Calcium hydroxyapatite***

Pure calcium hydroxyapatite ( $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$ ) does not occur in biological systems and biological apatites have been described as calcium-deficient or nonstoichiometric, carbonate apatites, fluorapatite, fluorhydroxyapatite, chlorapatite, and chlorhydroxyapatite.

Calcium-deficient apatites, such as  $\text{Ca}_{5-x}\text{Na}_{2x}(\text{PO}_4)_3(\text{OH})$ , are apatites with less than five calcium ions to three phosphates.

Carbonate apatites are apatites which contain carbonate ions in the structure. They are classified into A-type and B-type carbonate apatites depending on the substitution site. Substitution of hydroxide ions gives A-type carbonate apatites while

substitution of phosphate ions gives B-type carbonate apatites. Carbonate apatites occur in bone, enamel, and dentin at about 7.4, 5.6, and 3.5 wt %, respectively, and are mostly B-type carbonate apatites with different amounts of carbonate incorporated into the lattice.

Chlorhydroxyapatite, and fluorhydroxyapatite are apatites with hydroxide ions substituted by chloride or fluoride ions, respectively. Total substitution results in chlorapatite or fluorapatite. Chloride and fluoride ions occur in biological hard tissues such as bone (0.13 wt % and 0.03 wt %), enamel (0.30 wt % and 0.01 wt %), and dentin (0.01 wt % and 0.06 wt %).

#### ***Amorphous calcium phosphate***

Amorphous calcium phosphate ( $\text{Ca}_3(\text{PO}_4)_2$ ) containing magnesium ( $\text{Mg}^{2+}$ ), carbonate ( $\text{CO}_3^{2-}$ ), or pyrophosphate ( $\text{P}_2\text{O}_7^{4-}$ ) ions has been reported to occur in pathological calcifications.

#### ***Calcium hydrogen phosphate***

Anhydrous calcium hydrogen phosphate ( $\text{CaHPO}_4$ ) and calcium hydrogen phosphate dihydrate ( $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ ) occur in biological systems.  $\text{CaHPO}_4$  is speculated to form in carious lesions in the enamel while  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$  occurs in pathological calcifications. It is also proposed as a precursor of calcium hydroxyapatite.

***Octacalcium phosphate pentahydrate***

Octacalcium phosphate pentahydrate ( $2\text{Ca}_4\text{H}(\text{PO}_4)_3 \cdot 5\text{H}_2\text{O}$ ) occurs in pathological calcifications, and is also proposed as a precursor of calcium hydroxyapatite.

***Calcium phosphate***

Calcium phosphate ( $\text{Ca}_3(\text{PO}_4)_2$ ) occurs in dental and urinary calculi, salivary stones, and arthritic cartilage.

The occurrence of calcium-phosphate materials in biological systems is summarized in Table 1.5.

**Table 1.5** Occurrence of calcium-phosphate materials in biological systems, empirical formula, and stoichiometric Ca to P ratio.

Compound	Empirical formula	Ca/P	Occurrence
Calcium hydrogen phosphate dihydrate <sup>1</sup> , CHPD	$\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$	1.0	urinary calculi, crystalluria
Calcium hydrogen phosphate <sup>2</sup> , CHP	$\text{CaHPO}_4$	1.0	urinary calculi, crystalluria, decomposed bones
Calcium pyrophosphate dihydrate, CPPD	$\text{Ca}_2\text{P}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$	1.0	psuedo-gout deposits in synovium fluids
Octacalcium phosphate pentahydrate, OCP	$2\text{Ca}_4\text{H}(\text{PO}_4)_3 \cdot 5\text{H}_2\text{O}$	1.33	dental and urinary calculi
Calcium phosphate <sup>3</sup> , CP	$\text{Ca}_3(\text{PO}_4)_2$	1.5	dental and urinary calculi, salivary stones, arthritic cartilage
Amorphous calcium hydroxyapatite, ACaHAp	$\text{Ca}_5(\text{PO}_4)_3(\text{OH})$	1.67	pathological calcifications
Calcium hydroxyapatite, CaHAp	$\text{Ca}_5(\text{PO}_4)_3(\text{OH})$	1.67	enamel, dentine, bone, dental calculi, urinary calculi

<sup>1</sup>Also called dicalcium phosphate dehydrate (DCPD) or brushite (LeGeros, 1991)

<sup>2</sup>Also called dicalcium phosphate (DCP) or monetite (LeGeros, 1991)

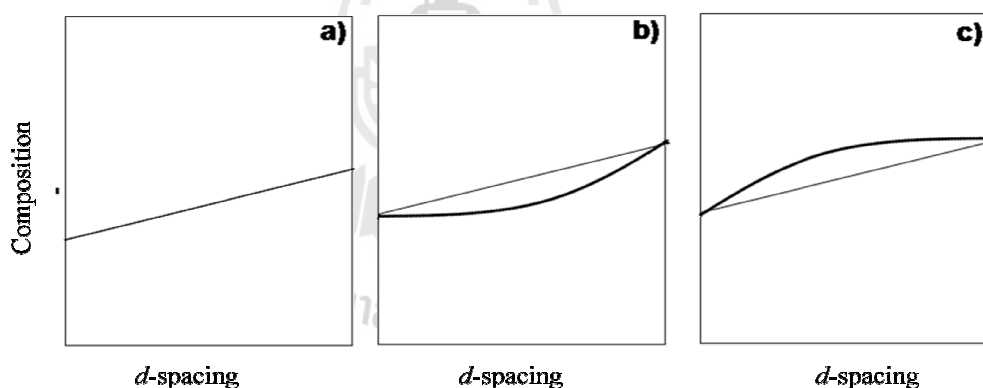

<sup>3</sup>Also called Tricalcium phosphate (TCP) (LeGeros, 1991)

## 1.4 Solid solutions

Many minerals including apatite materials occur as solid solutions. West (1984) defines a “solid solution as solid state phenomena wherein the composition of a material varies significantly within the framework of the same overall crystal structure”. When the ion exchange reaction in CaHAp is complete, another apatite

member in the apatite or pyromorphite series, depending on the ions substituted, has formed. Incomplete or partial substitution in the CaHAp structure may result in the formation of hydroxyapatite solid solution. Some examples of hydroxyapatite solid solutions are magnesium-calcium hydroxyapatite, strontium-lead hydroxyapatite, calcium phosphate fluorhydroxylapatite (Patel, 1980; Zhu, *et al.*, 2007; Rodriguez-Lorenzo, Hart, and Gross, 2003), and calcium phosphate-arsenate hydroxyapatite (Mahapatra, Mahapatra, and Mishra, 1989).

Vegard's law is often used when characterizing homogeneous solid solution phases and other materials resulting from coprecipitation of insoluble materials. The law states that, unit cell parameters change linearly with composition as seen in Figure 1.4a.

**Figure 1.4** Vegard's law behavior. a) ideal solid solution, b) negative deviations, and c) positive deviations (West, 1984).

However, the law often holds approximately, and accurate measurements reveal both negative (Figure 1.4b) and positive (Figure 1.4c) deviations from linearity (West, 1984).

The potential for nonideal behavior, similar to nonideal behavior of normal solutions, suggests caution should be used when assuming a material is a solid

solution and that its properties are the weighted average of the pure component end points of the assumed solid solution.

## 1.5 Lead-phosphate materials

Lead-phosphate (Pb-P) materials such as lead hydroxyapatite, PbHAp, ( $\text{Pb}_5(\text{PO}_4)_3(\text{OH})$ ), lead hydrogen phosphate ( $\text{PbHPO}_4$ ), lead nitrate phosphate monohydrate ( $\text{Pb}_2(\text{NO}_3)(\text{PO}_4)\cdot\text{H}_2\text{O}$ )<sup>1</sup>, and lead phosphate ( $\text{Pb}_3(\text{PO}_4)_2$ ) are interesting materials due to their structure and properties. PbHAp is a material of biological interest because of the similarity to CaHAp.  $\text{PbHPO}_4$  and  $\text{Pb}_2(\text{NO}_3)(\text{PO}_4)\cdot\text{H}_2\text{O}$  show dielectric, piezoelectric, and optical properties which are useful in transducers and memory devices.  $\text{Pb}_3(\text{PO}_4)_2$  is a ferroelastic material with a phase transition near 180 °C. The phase is changed from  $\alpha$ -phase ( $C2/c$  ferroelastic phase) at below 180 °C to  $\beta$ -phase ( $R\bar{3}m$  prototypic phase) at above 180 °C (Guimaraes, 1979; Decker, Petersen, and Debray, 1979). Growth of  $\text{PbHPO}_4$  and  $\text{Pb}_2(\text{NO}_3)(\text{PO}_4)\cdot\text{H}_2\text{O}$  in silica hydrogel, tetramethoxysilane gel, cross-linked polyacrylamide gel, agar gel, and gelatin, all beginning from  $\text{Pb}(\text{NO}_3)_2$  and  $\text{H}_3\text{PO}_4$ , but with different concentrations of reactants and gel medium, and different techniques has been reported (Březina, Havránková, and Dušek, 1976; Desai and Ramana, 1990; Vivekanandan, Selvasekarapandian, and Kolandaivel, 1995; Mayer and Woermann, 1996; Desai and Ramana, 1988; Robert and Lefauchaux, 1988). A summary of the crystallization of lead and phosphate containing materials in gel systems is given in Table 1.6.

---

<sup>1</sup>This formula is often reported as double formula,  $\text{Pb}_4(\text{NO}_3)_2(\text{PO}_4)_2\cdot 2\text{H}_2\text{O}$

**Table 1.6** Summary of gel crystallization reports of lead hydrogen phosphate and lead nitrate phosphate dihydrate materials.

<b>Gel medium</b>	<b>Technique</b>	<b>Products</b>	<b>Reference</b>
Polyacrylamide, poly(2-hydroxyl ethylacrylate), sodium metasilicate, agar, gelatin	Double diffusion	PbHPO <sub>4</sub> and Pb <sub>2</sub> (NO <sub>3</sub> )(PO <sub>4</sub> )·H <sub>2</sub> O	Březina <i>et al.</i> , 1976
Sodium metasilicate	Single diffusion	PbHPO <sub>4</sub> and Pb <sub>2</sub> (NO <sub>3</sub> )(PO <sub>4</sub> )·H <sub>2</sub> O	Desai <i>et al.</i> , 1988
Tetramethoxysilane	Double diffusion	PbHPO <sub>4</sub> and Pb <sub>2</sub> (NO <sub>3</sub> )(PO <sub>4</sub> )·H <sub>2</sub> O	Robert <i>et al.</i> , 1988
Silica gel	Single diffusion	PbHPO <sub>4</sub>	Desai <i>et al.</i> , 1990
Sodium metasilicate	Single diffusion	Pb <sub>2</sub> (NO <sub>3</sub> )(PO <sub>4</sub> )·H <sub>2</sub> O	Vivekanandan <i>et al.</i> , 1995
Methoxysilane	Single diffusion	PbHPO <sub>4</sub> and Pb <sub>2</sub> (NO <sub>3</sub> )(PO <sub>4</sub> )·H <sub>2</sub> O	Mayer <i>et al.</i> , 1996

However, the preparation of PbHAp material by gel crystallization methods or the appearance of this material in a gel system has not been reported (Březina, Havráňková, and Dušek, 1976; Desai and Ramana, 1990; Vivekanandan, Selvasekarapandian, and Kolandaivel, 1995; Mayer and Woermann, 1996; Desai and Ramana, 1988; Robert and Lefauchaux, 1988).

The formula of Pb<sub>2</sub>(NO<sub>3</sub>)(PO<sub>4</sub>)·H<sub>2</sub>O compound in Table 1.6 was reported as a double formula (Pb<sub>4</sub>(NO<sub>3</sub>)<sub>2</sub>(PO<sub>4</sub>)<sub>2</sub>·2H<sub>2</sub>O) in the literature. Březina, Havráňková, and Dušek (1976) first reported the nonempirical Pb<sub>4</sub>(NO<sub>3</sub>)<sub>2</sub>(PO<sub>4</sub>)<sub>2</sub>·2H<sub>2</sub>O compound as a double formula and their work was cited by Robert and Lefauchaux (1988) and Desai and Ramana (1988). Later works of Vivekanandan, Selvasekarapandian, and

Kolandaivel (1995) and Mayer and Woermann (1996) cited the Desai and Ramana (1988) and Robert and Lefauchaux (1988) papers and propagated the error.

Conventionally nonmolecular compounds are reported as empirical formula units using subscripts that do not contain common factors. The importance of this is discussed in Appendix A (pp. 108-109). The mistake of the formula affects reported values of physical constants such as the  $K_{sp}$  value.  $K_{sp}$  is calculated using the number of atoms in the formula as exponents leading to dramatic discrepancies. Discussion of the  $K_{sp}$  value problem from the wrong formula is given in Appendix A.

## 1.6 Dissolution equilibria aspects

The solubility of a pure phase compound to make an aqueous solution is the maximum amount of the compound that can be dissolved in a given quantity of pure water at a given temperature. For molecular compounds and reasonably soluble ionic compounds solubility is generally expressed as g/100 mL of saturated solution.

The dissolution of an ionic compound is generally represented by a chemical equilibrium, as for example, for dissolution of barium sulfate:

where  $s$  indicates solid phase material, and  $aq$  indicates the species in solvated form in the aqueous solution, and the double arrow indicates the process is at chemical equilibrium. The conventional mathematical description of this equilibrium is usually in terms of  $K_{eq}$ , the equilibrium constant expression:

$$K_{\text{eq}} = [\text{Ba}^{2+}(\text{aq})][\text{SO}_4^{2-}(\text{aq})] / [\text{BaSO}_4(\text{s})] \quad \dots\dots\dots(1.2)$$

where the square brackets denote molar concentrations. If we assume the activity of the pure solid in equilibrium with the saturated solution is equal to one this expression reduces to the solubility product,  $K_{\text{sp}}$ , expression:

$$K_{\text{sp}} = [\text{Ba}^{2+}(\text{aq})][\text{SO}_4^{2-}(\text{aq})] \quad \dots\dots\dots(1.3)$$

a form that is correct for ideal (infinitely dilute) solutions. In a real (nonideal) solution, the species also interact with one another, changing their effective participation (activity) in the equilibrium reaction. Empirical corrections are introduced as coefficients to the molar concentrations to account for the decreased activities as follows:

$$K_{\text{sp}} = [\text{Ba}^{2+}(\text{aq})]\gamma^+[\text{SO}_4^{2-}(\text{aq})]\gamma^- \quad \dots\dots\dots(1.4)$$

where  $\gamma^+$  and  $\gamma^-$  are the activity coefficients of cations and anions, respectively.

Analytical techniques, such as fluorescence spectroscopy, atomic absorption spectroscopy, or inductively-coupled plasma mass spectrometry, give total concentrations of the elemental species in the sample being analyzed. However, for equilibrium studies, the concentrations of the individual chemical (ionic) species present in the solution are required, but may be difficult to obtain experimentally. Additionally, concentrations of the individual chemical (ionic) species are affected by any additional ions in the solution (*i.e.* NaOH and HCl from adjusting pH) due to the

interactions among the competing ionic equilibria in the system. A previous study has discussed the effect of  $\text{Na}^+$  cation and  $\text{Cl}^-$  anion on the barium-arsenate system (Dungkaew, 2010). The results of that showed that with high  $\text{Cl}^-$  concentration (pH = 10.5),  $\text{Ba}_5(\text{AsO}_4)_3\text{Cl}$  precipitates, and if the pH of system is increased to pH = 12.5 by adding more NaOH,  $\text{Na}^+$  concentration is increased and  $\text{NaBaAsO}_4 \cdot 9\text{H}_2\text{O}$  precipitates.

Hence,  $K_{\text{sp}}$  calculations based on only the molar concentrations of a single ionic compound may be seriously in error. The solution to this problem will involve the careful consideration and correct inclusion of all relevant equilibrium phenomena. The PHREEQC speciation calculation program has been used to calculate the activity coefficients of ions in the system (Dungkaew, Haller, Flood, and Scamehorn, 2012). Calculation of the  $K_{\text{sp}}$  based on molar concentrations and activity coefficients could be more correct.

## 1.7 Characterization background

### *PHREEQC program*

PHREEQC is a computer program for simulating chemical reactions and transport processes based on equilibrium chemistry of aqueous solutions interacting with solids and gases. It can be used as a speciation program to calculate saturation indices and distribution of aqueous species and competing equilibria that change the concentration of the species, effects of ionic strength (Parkhurst and Appelo, 1999).

The PHREEQC calculations are based on all known equilibria existing in the database. PHREEQC is distributed with a PHREEQC default internal database, and the Minteq, MinteqV4, and Wateq4f databases. Input data for the program consists of

properties and compositions of equilibrated solutions, including pH, temperature, and total concentrations of ions in the system.

Saturation index (SI) is calculated by the PHREEQC program based on input data. SI uses calculated activities to provide a good indicator of the potential solid phases in a system at its equilibrium state. SI is defined as Eq. (1.5):

$$SI = \log \left( \frac{IAP}{K_{sp}} \right) \quad \dots\dots\dots(1.5)$$

where IAP is the free ionic activity product and  $K_{sp}$  is the thermodynamic solubility product constant of a pure precipitate phase. SI relates to  $\Delta G$  (Stumm and Morgan, 1996) as,

$$\Delta G = -2.303RT \log \left( \frac{IAP}{K_{sp}} \right) \quad \dots\dots\dots(1.6)$$

where  $R$  is the ideal gas constant, and  $T$  is the temperature. From Eq. (1.6),  $\Delta G$  equals zero when  $IAP = K_{sp}$  corresponding to  $SI = 0$  and the solution is in equilibrium;  $\Delta G$  is negative when  $IAP > K_{sp}$  corresponding to  $SI > 0$ ; the solution is supersaturated and precipitation can occur (unless a metastable supersaturated solution occurs). However,  $\Delta G$  is positive when  $IAP < K_{sp}$  corresponding to  $SI < 0$  and the solution is undersaturated so precipitation cannot occur.

### ***Powder X-ray diffraction***

XRD is a useful technique to characterize the crystallographic structure, crystallite size (grain size), and preferred orientation in polycrystalline or powdered solid samples. XRD is commonly used to identify unknown substances, by comparing diffraction data with a database maintained by the International Center for Diffraction Data (ICDD). It may also be used to characterize heterogeneous solid mixtures to determine relative abundance of crystalline compounds. XRD can provide structural information of unknown materials by Rietveld refinement method.

XRD patterns are typically plotted as the intensity of the diffracted X-rays versus the angle  $2\theta$ . The diffracted X-ray beam is considered as “reflection” from a lattice plane as described by Bragg’s Law (Eq. 1.7):

$$n\lambda = 2d \sin \theta \quad \dots\dots\dots(1.7)$$

where  $n$  is the order of diffraction of X-rays,  $\lambda$  is wavelength,  $d$  is the perpendicular spacing of the lattice planes, and  $\theta$  is the diffraction angle as shown in Figure 1.5.

**Figure 1.5** The incident and reflected beams relative to the planes.

Peaks will appear in the diffraction pattern at  $2\theta$  values when constructive interference is at a maximum. By measuring the  $2\theta$  values for each diffraction peak, we can calculate the  $d$ -spacing (the distance between the diffracting planes) for each diffraction peak. The data analysis software has a program for automatically calculating the  $d$ -spacing for all of the peaks in the diffraction pattern.

The number of observed peaks is related to the symmetry of the unit cell. The  $d$ -spacings of the observed peaks are related to the repeating distances between planes of atoms in the structure and the intensities of the peaks are related to the kinds of atoms and their arrangements within the unit cell. The scattering intensities for the diffracted beams are directly related to the number of electrons in the atom. Hence, light atoms scatter X-rays weakly, while heavy atoms scatter X-rays more effectively. These three features of a diffraction pattern (the number of peaks, the positions of the peaks, and the intensities of the peaks) define a unique, fingerprint XRD pattern for every crystalline material.

A unit cell contains basis vectors of the direct lattice **a**, **b**, and **c**. The lengths of the basis vectors **a**, **b**, and **c** are  $a$ ,  $b$ , and  $c$ , respectively and the interaxial (lattice) angles between **b** and **c**, **c** and **a**, and **a** and **b** are  $\alpha$ ,  $\beta$ , and  $\gamma$ , respectively (Hahn, 1996).

### ***Fourier transform infrared spectroscopy***

Fourier transform infrared spectroscopy (FT-IR) is a technique for characterizing and identifying functional groups in organic molecules. The characterization is achieved by comparison with the spectra in databases and assigning each peak to the vibration of a specific functional group.

Principle of the FTIR technique is based on the interaction between the radiation and the sample. When infrared light interacts with a sample, materials are excited to a higher energy state. A material adsorbs only selected frequencies (energies) of the infrared radiation which match the energy differences between orbitals in the material. Therefore, vibrational modes of different chemical interactions can be detected and allow the identification of different materials. The energy of an interaction is changed in an 8 to 40 kJ/mole range corresponding to the stretching and bending vibrational frequencies of the bonds in material (Pavia, Lampman, and Kriz, 1996).

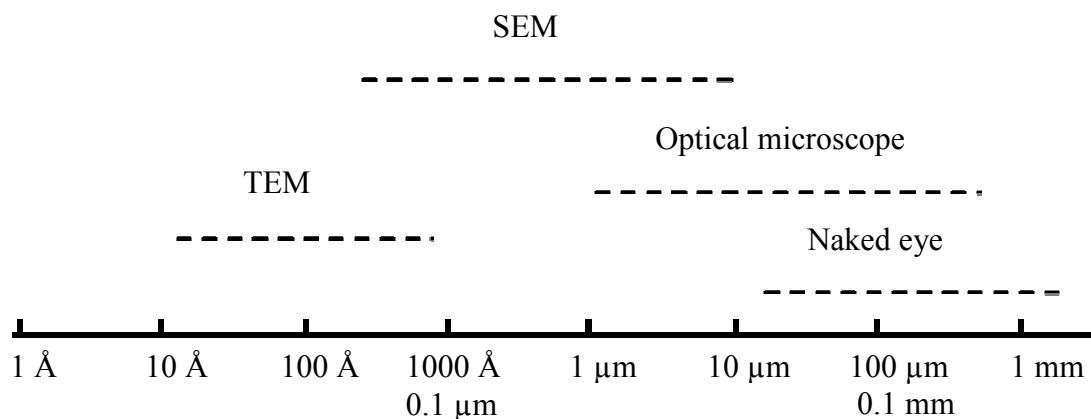

As mentioned, infrared light matches the vibrational frequencies of the interactions. In order for a vibration to be “IR active”, it is necessary for a change in the dipole moment during absorption of the infrared light. For example hydrochloric acid, HCl, when HCl vibrates along the bond, the chlorine takes on a slightly more negative charge, and the hydrogen takes on a slightly more positive charge.

Consequently, a change in dipole moment of the HCl molecule occurs. In some molecules, such as O<sub>2</sub>, N<sub>2</sub>, H<sub>2</sub>, F<sub>2</sub>, and Cl<sub>2</sub> there is no induced dipole moment and they are “IR-inactive”. These compounds require use of other techniques to study interaction strengths such as Raman spectroscopy.

There are three regions of the infrared spectrum; the near-, mid- and far-infrared. The far-infrared is approximated in 400-10 cm<sup>-1</sup> range, has low energy and may be used for rotational spectroscopy. The mid-infrared in 4000-400 cm<sup>-1</sup> range may be used to study the fundamental vibrations and associated rotational-vibrational structure. The higher energy near-IR (14000-4000 cm<sup>-1</sup>) can excite overtone or harmonic vibrations.

### ***Electron microscopy***

Scanning electron microscopy (SEM) and transmission electron microscopy (TEM) are techniques capable of providing structural information over a wide range of magnification. SEM is useful for studying morphology and surface features of samples which have size up to 10 μm, because of the depth focus of SEM instruments, the resulting picture is obtained with a three dimensional appearance. For TEM technique, samples should be thinner than 2000 Å because electrons interact strongly with matter and are completely absorbed by thick particles. The range of various techniques used to observe the morphology of samples are given in Figure 1.6 (West, 1984).

**Figure 1.6** The range of various techniques used to observe the morphology of samples.

SEM operates from a source of electrons focused in vacuum into a fine probe that is modulated over the surface of the specimen. The electron beam passes through scan coils and objective lens that deflect it horizontally and vertically so the beam scans the surface of the sample. As the electrons penetrate the surface, a number of interactions occur that can result in the emission of electrons or photons from or through the surface. A reasonable fraction of the electrons emitted can be collected by appropriate detectors, and the output can be used to modulate the brightness of a cathode ray tube (CRT) whose x- and y-inputs are driven synchronously with the x-y voltages modulating the electron beam. In this way an image is produced on the CRT; every point that the beam strikes on the sample is mapped directly onto a corresponding point on the screen. The operation of TEM is similar to SEM and requires an ultra high vacuum and a high voltage.

### ***X-ray fluorescence spectroscopy***

When a sample is bombarded with high energy electrons many things can happen, including generation of X-rays. These X-rays are characteristic emission spectra of the elements present in the sample. Analysis of the emitted radiation can use either wavelength dispersive X-ray fluorescence (WDX) or energy dispersive X-ray fluorescence (EDX) to identify the elements in the sample. These techniques are useful for quantitative and qualitative analysis. However, these techniques can determine only elements heavier than and including fluorine. Lighter elements do not give suitable X-ray spectra.

### ***Optical/polarizing microscopy***

An optical or polarizing microscope is an optical measuring instrument for the detailed examination of specimens. The basic components of the microscope are shown in Figure 1.7 and 1.8. The source may give either white or monochromatic light. The light shines on the polarizer and only that component which vibrates parallel to the polarizer is permitted to pass through. The resulting polarized light passes through the sample. There are two variants of the analyzer position. In one the transmitted light is picked up by the objective lens, and the analyzer may be placed in or out of the path of light inside of the microscope (West, 1984).

**Figure 1.7** Basic components of a polarizing microscope.

In the second variant the analyzer is placed below the objective lens, exterior to the body of the microscope (Figure 1.7). Objective or eyepiece lenses may be available for different magnifications and/or the body of the microscope may include a zoom function, often called a power body.

**Figure 1.8** Alternative arrangement of the basic components of a polarizing microscope.

## CHAPTER II

# STRUCTURAL ANALYSIS OF CALCIUM AND LEAD HYDROXYAPATITE<sup>1</sup>

### 2.1 Introduction

Apatite is a class of mineral including two series, apatite and pyromorphite series. Calcium hydroxyapatite, CaHAp ( $\text{Ca}(1)_2\text{Ca}(2)_3(\text{PO}_4)_3\text{OH}$ ) is the prototype of the apatite class and of the apatite series. The structure belongs to space group  $P6_3/m$  and is susceptible to ionic substitution in both anion and cation sites.  $\text{Ca}^{2+}$  can be replaced by various divalent cations such as  $\text{Ba}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Sr}^{2+}$ , or  $\text{Pb}^{2+}$  (Sugiyama *et al.*, 1999; Yasukawa, Yokoyama, Kandori, and Ishikawa, 2007; Barinova, Lusvardi, Menabue, and Saladini, 1998),  $\text{PO}_4^{3-}$  can be replaced by  $\text{AsO}_4^{3-}$  or  $\text{VO}_4^{3-}$ , and  $\text{OH}^-$  can be replaced by  $\text{F}^-$  or  $\text{Cl}^-$  (Dong, White, Wei, and Laursen, 2002; Dai and Hughes, 1989). Apatites are important materials for environmental remediation, including applications in removal of heavy metals from contaminated water (Mavropoulous, Rossi, and Costa 2002; Mavropoulous, Rocha, Moreira, Rossi, and Soares, 2004; Admassu and Breese, 1999; Smičiklas, Onjia, Raičević, Janačković, and Mitrić, 2008) and immobilization of toxic and/or radioactive ions (Krestou, Xenidis, and Panias, 2004). Apatites are also important, because CaHAp is the dominant component in mammalian hard tissues such as bones and teeth;

---

<sup>1</sup>Portions of this work have been published in the proceedings of the 35<sup>th</sup> Congress on Science and Technology of Thailand (Saisa-ard and Haller, 2009).

about 69 wt % and 95 wt %, respectively (Aoba, 1997). Divalent metal ions such as  $\text{Pb}^{2+}$  can substitute for  $\text{Ca}^{2+}$  ions of CaHAp. Complete substitution of  $\text{Pb}^{2+}$  ions into CaHAp results in lead hydroxyapatite (PbHAp) which is isostructural with CaHAp. The relationship of PbHAp to CaHAp and its link to bone disease is one reason the structure of PbHAp is of interest.

Bond valence calculation is a method which can be used to determine the apparent formal valence of each atom in an ionic crystal structure by calculating partial bond valences from the individual bond lengths, then summing all the components about each atom to obtain its total bond valence. It is common practice in the structure determination of ionic crystal structures to assess the correctness of the results from these bond valence sums. If the sum of the bond valences around each atom is close to the expected formal oxidation state, the structure is likely to be correct. However, if the bond valence sum for any atom deviates from the expected value by more than 0.1 valence unit (v.u.) the result must be examined critically and the discrepancy explained, or the structural error corrected (Brown, 1993).

Bond valence calculations have been used for structural analysis of PbHAp and CaHAp (Saisard and Haller, 2009). Results show the bond valence sums for all atoms of CaHAp are acceptable, but the bond valence sums of P, Pb in the M(2) site, and O(4) (5.66, 1.55, and 0.67, respectively) in PbHAp are dramatically different from integral values. The discrepancies in the expected bond valence sum values of these atoms may come from several causes such as an incorrect origin choice or structure distortions. The results are not optimal and additional work is required, however, the result suggests that part of the error in the PbHAp structure is likely from the unusual (probably incorrect) distortion of the  $\text{PO}_4^{3-}$  group with the O(3)

atom moved closer to the O(1) and O(2) positions, resulting in a larger O(3)–P–O(3i) angle (larger by 4.3°) and effectively decreasing the P–O(3) and the Pb(2)–O(3) bond lengths but increasing the O(3) bond lengths to the Pb(1) in the M(1) site.

The public-domain bond-valence program (Brown, 1993) is easy to use. However, using the program to evaluate a series of isostructural compounds is unnecessarily tedious, and in assessing structures with deviant atoms, interatomic distances and angles are also useful. Therefore, part of this work was construction of a tool which calculates the bond valence components, the relevant bond valence sums, and relevant interatomic distances and angles for all the crystallographically unique atoms and structural parameters in the apatite structure. Evaluation of alternate models is facilitated by the instantaneous availability of the bond valences, bond lengths, and bond angles on modification of any coordinate or atom type. Use of the calculator is illustrated by the example of PbHAp which, as published from powder diffraction data, has some unusual bond lengths and angles as well as unexpected bond valence sums.

## 2.2 Theory

### *Bond valence*

The concept of bond valence derives from the Pauling electrostatic valence model (Pauling, 1929). The bond valences are calculated from simple expressions using empirically derived constants. The partial bond valence,  $s_{ij}$ , between any pair of adjacent atoms is given by:

$$s_{ij} = \exp[(R_o - R_{ij})/b] \quad \dots\dots\dots(2.1)$$

where the bond valence between adjacent atoms  $i$  and  $j$  is related to the observed bond length  $R_{ij}$ ;  $R_o$  is a constant depending on the nature of the  $ij$  pair, and  $b$  is 0.37. The bond valence sum for a given atom or ion,  $z_j$ , is defined as the sum of all the individual bond valences as follows:

$$z_j = \sum s_{ij} \quad \dots\dots\dots(2.2)$$

The atoms to be summed over are determined by the criteria that a) every part of the electron density of the crystal must belong to at least one atom, b) the division of the electron density must ensure a reasonable assignment of the charges in the crystal, and c) the division and charges are chosen to minimize the local multipole energies associated with nonspherical charge distributions in most crystals (Brown, 2002).

### **Geometry**

Interatomic distance,  $d_{A-B}$ , and interatomic angles,  $\angle_{A-B-C}$ , can be calculated from Cartesian coordinates,  $(X, Y, Z)$ , as follows:

$$d_{A-B} = \sqrt{(X_A - X_B)^2 + (Y_A - Y_B)^2 + (Z_A - Z_B)^2} \quad \dots\dots\dots(2.3)$$

$$= \sqrt{\Delta X_{A-B}^2 + \Delta Y_{A-B}^2 + \Delta Z_{A-B}^2} \quad \dots\dots\dots(2.4)$$

$$\angle_{A-B-C} = \arctan (\sqrt{1-c_A^2} / c_A) \quad \dots\dots\dots(2.5)$$

$$\text{where } c_A = -(\Delta X_{A-B}\Delta X_{B-C} + \Delta Y_{A-B}\Delta Y_{B-C} + \Delta Z_{A-B}\Delta Z_{B-C}) / (d_{A-B}d_{B-C}) \quad \dots\dots\dots(2.6)$$

Crystallographic data are normally presented as fractional coordinates referred to the crystallographic unit cell parameters  $a$ ,  $b$ ,  $c$ ,  $\alpha$ ,  $\beta$ ,  $\gamma$ , and the crystallographic space group. While this form may at first seem inconvenient, it preserves the power and convenience of the crystalline symmetry. Fractional triclinic coordinates  $(x, y, z)$  may be converted to Cartesian coordinates as follows:

$$X = xa + yb \cos \gamma + zc \cos \beta \quad \dots\dots\dots(2.7)$$

$$Y = yb \sin \gamma + z\{c(\cos \alpha - \cos \beta \cos \gamma) / \sin \gamma\} \quad \dots\dots\dots(2.8)$$

$$Z = zcW / \sin \gamma \quad \dots\dots\dots(2.9)$$

$$\text{where } W = \sqrt{(1 - \cos^2 \alpha - \cos^2 \beta - \cos^2 \gamma + 2 \cos \alpha \cos \beta \cos \gamma)} \quad \dots\dots\dots(2.10)$$

In a conventional hexagonal crystal system, such as that of apatite,  $a = b$ ,  $\alpha = \beta = 90^\circ$ , and  $\gamma = 120^\circ$ , leading to simplification of equations 2.7, 2.8, and 2.9.

$$X = a(x - y/2) \quad \dots\dots\dots(2.11)$$

$$Y = ya \frac{\sqrt{3}}{2} \dots\dots\dots(2.12)$$

$$Z = zc \dots\dots\dots(2.13)$$

## 2.3 Experimental

A spreadsheet was constructed in Excel (Microsoft Office Excel, 2003). The input section accepts values for the hexagonal fractional coordinates of the seven crystallographically unique atom positions, the lengths of the *a* and *c* axes, and the values of *R<sub>o</sub>* for Pb–O, P–O, and O–H atom pair types. Equations as defined in section 2.2 above were entered into the following area to create two additional sections. The center section presents the calculated interatomic distances and interbond angles about the two crystallographically unique metal sites and the phosphate site, and the final section presents a summary table of the bonds combined with the bond valence sums for each crystallographically unique atom.

The crystallographic information file, *cif* file, for the PbHAp structure (Barinova, Lusvardi, Menabue, and Saladini, 1998) utilized in this work was obtained from supporting information available via the Inorganic Crystal Structure Database, ICSD (Inorganic Crystal Structure Database, 2008), ICSD code 87518. Crystal data and positional parameters of each atom of the PbHAp compound are given in Table 2.1.

Atomic positions, unit cell parameters, and the bond valence interaction parameters *R<sub>o</sub>* were entered into the bond valence calculator and the structure was

adjusted to be more chemically reasonable by adding an H atom and changing the positions of O(3) and O(4) as discussed in the following section.

**Table 2.1** Crystal data and fractional hexagonal coordinates for PbHAp.

<b>Parameter</b>	<b>PbHAp</b>		
Empirical formula	Pb <sub>5</sub> (PO <sub>4</sub> ) <sub>3</sub> OH		
Crystal system	hexagonal

O(H)	0	0	0

## 2.4 Results and discussion

The metal atoms in apatite structures are located on two crystallographically different sites<sup>1</sup>: *h* sites, mirror planes at  $z = 1/4$  and  $3/4$ , and *f* sites, 3-fold axes at  $(1/3, 2/3, z)$  and  $(2/3, 1/3, z)$ , as shown in Figure 2.1. Three P atoms and six phosphate O atoms are also located on *h* sites while the other six phosphate O atoms are located on general positions, pairwise related by the mirror planes through the P atoms. Three metal ions at the *h* sites are coordinated with seven O atoms (one O(1), one O(2), and four general O(3) atoms from  $\text{PO}_4^{3-}$  groups and one O atom from an  $\text{OH}^-$  group), and two metal ions at the *f* sites are coordinated with nine O atoms (six shorter bonds to three O(1) and three O(2) phosphate oxygen atoms on *h* sites define a twisted trigonal prism, and three longer bonds to O(3) atoms extend through the prism faces). The hydroxyl O positions are disordered along the 3-fold axis with the hydrogen atom further disordered into general positions about the 3-fold axis, consistent with hydrogen bonding to O(3) positions.

---

<sup>1</sup>Wyckoff special positions are represented by letters, starting with *a* for the most symmetric special position in the space group under consideration, and continuing in alphabetical order until the general position is reached.

**Figure 2.1** Representation of Ca, O, and P atoms in the CaHAp structure projected on the *ab* plane.

Calculated structural parameters and bond valence sums based on the published PbHAp structure are given in Table 2.2.

**Table 2.2** Bond valence sums, bond lengths, and oxidation states for the unique atoms of PbHAp. The adjusted structural model has a modified O(3) atom position.

Atoms	Published structure		Adjusted structure		Formal oxidation state
	Bond length (Å)	Bond valence sum (v.u.)	Bond length* (Å)	Bond valence sum (v.u.)	
	P	5.66	P	4.90	+5
O(1)	1.542	2.02		2.02	-2
O(2)	1.542	2.08		2.08	-2
O(3)	1.442†	2.03	1.542†	1.69	-2
	Pb(1)	1.91	Pb(1)	1.96	+2
O(1)	2.511†	2.02		2.02	-2
O(2)	2.720†	2.08		2.08	-2
O(3)	2.893†	2.03	2.898†	1.69	-2
	Pb(2)	1.55	Pb(2)	1.62	+2
O(1)	2.921	2.02		2.02	-2
O(2)	2.391	2.08		2.08	-2
O(3)	2.745†	2.03	2.610†	1.69	-2
O(3i)	2.628†	2.03	2.703†	1.69	-2
O(4)	2.926	0.66		0.66	-2

\*Only values which are modified are given.

†Bond lengths repeated by symmetry are not listed.

The general position, O(3), appeared to be misplaced based on rational values of P–O bond lengths. Specifically, the bond length of 1.442 Å is about 0.1 Å shorter than the other two P–O bond lengths which are in good agreement with structure correlation results (Burgi and Dunitz, 1994). Furthermore, the bond valence sum for P is 0.66 v.u. high, while that for Pb(2) is 0.45 v.u. low. The O(1)–P–O(2) angle of 110.82° is close to the ideal  $T_d$  angle of 109.54°. The positions of O(3) and its mirror related general counterpart were adjusted to give a geometrically idealized phosphate group with approximate  $T_d$  symmetry and  $d[\text{P–O}] = 1.542$  Å (the two O(3) positions are constrained to be on the plane that bisects O(1)–P–O(2), with ideal  $T_d$  angles to both O(1) and O(2)). The adjusted bond lengths and bond valence sums are given in the right-hand section of Table 2.2.

The results after adjustment show the potential effect of the idealization of O(3) on the bond valence sums of P and Pb(2). The bond valence sum of P moves near to its expected oxidation state value. However, the bond valence sum of Pb(2) ion, while improved is still considerably below its expected oxidation state value.

The bond valence sum of the hydroxide oxygen atom, O(4), is also problematic. One obvious component of error in the bond valence sum of O(4) is the neglect of the hydrogen atom in the published structure. Including a hydrogen atom on the 3-fold axis 0.983 Å (Steiner, 2002) from O(4) increases the bond valence sum of O(4) to 1.55 v.u. A second component of error for O(4) is its location at  $z = 0$  making its closest contact to a Pb(2) ion 2.926 Å. Adjusting the O(4) position along the 3-fold axis would move O(4) toward Pb(2), and away from Pb(2)', thereby increasing the bond valence contribution to both Pb(2) and O(4). The O(4) atom was moved from (0, 0, 0) to (0, 0, 0.1200) producing the changes shown in Table 2.3.

**Table 2.3** Bond valence sums, bond lengths, and oxidation states of atoms in the modified structural models.

Atom	Structure with adjusted O(3)		Further adjustment with hydroxide anion		Formal oxidation state
	Bond length (Å)	Bond valence sum (v.u.)	Bond length* (Å)	Bond valence sum (v.u.)	
Pb(2)		1.62	Pb(2)	1.88	+2
O(1)	2.921	2.02		2.02	-2
O(2)	2.391	2.08		2.08	-2
O(3)	2.610†	1.69		1.69	-2
O(3i)	2.703†	1.69		1.69	-2
O(4)	2.926	0.66	2.477‡	2.07	-2
O(4)'	2.926	0.66	3.538‡	2.07	-2

\*Only values which are modified are given.

†Bond lengths repeated by symmetry are not listed.

‡O(4) connects to six Pb(2) positions when O(4) is on the 3-bar site all contacts are equivalent, but on adjustment along the 3-fold, three contacts are short at 2.4773 Å and three are long at 3.5378 Å.

The bond valence sums of O(3) and Pb(2) after the modification still exhibit discrepancies in expected oxidation state values.

## 2.5 Conclusions

Results of modification of O(3) and O(4) atom positions in the PbHAp structure discussed here improved the internal agreement of the bond valence sums, but they are still not optimal. However, they do suggest that there is probable error in the published PbHAp structure model, and the alternative model formed with guidance of bond valence sums and geometric considerations would be a better

starting point for a new refinement against X-ray data. The ease of use of this tool makes it potentially useful for guiding constraints and restraints for apatite structural models during the refinement in data poor cases. It is also a useful tool for evaluation of any published apatite structure.

# CHAPTER III

## PHASE CHARACTERIZATION AND SATURATION

### MODELING OF CALCIUM-LEAD HYDROXYAPATITE

#### SOLID SOLUTION

### 3.1 Introduction

Structure of calcium hydroxyapatite, CaHAp ( $\text{Ca}(1)_2\text{Ca}(2)_3(\text{PO}_4)_3(\text{OH})$ ) contains four positions;  $\text{Ca}^{2+}(1)$ ,  $\text{Ca}^{2+}(2)$ ,  $\text{PO}_4^{3-}$ , and  $\text{OH}^-$  that can be replaced by other cations or anions as explained in chapter 1 (pp. 11-15). Its structure belongs to space group  $P6_3/m$ . There are two Wyckoff positions,  $f$  and  $h$ , relevant to apatite structure. Ca(1) is located on  $f$  sites and coordinated with nine phosphate oxygen atoms while Ca(2) is located on  $h$  sites and coordinated with seven oxygen atoms (six phosphate oxygen atoms and one hydroxyl oxygen atom). Incomplete or partial substitution of  $\text{Ca}^{2+}$  by other cations may result in apatite solid solution materials. Studies of apatite solid solutions have been reported, including calcium-cadmium hydroxyapatite solid solution (Ca-CdHAp), calcium-strontium hydroxyapatite solid solution (Ca-SrHAp), calcium-lead hydroxyapatite solid solution (Ca-PbHAp), and lead-strontium hydroxyapatite solid solution (Pb-SrHAp) (Yaskawa, Higashijima, Kandori, and Ishikawa, 2005; Zhu, Yanagisawa, Shimanouchi, Onda, and Kajiyoshi, 2006; Zhu, Yanagisawa, Shimanouchi, Onda, Kajiyoshi, and Qiu, 2009). The preferential occupancy of alternate metal ions in the hydroxyapatite solid

solutions is in the M(2) sites due to two reasons. One is the arrangement of ions in the M(2) sites located on staggered triangles allows for the optimization of packing of larger ions, in contrast, the M(1) sites are located in the column and have strict alignment. Therefore, the substitution by larger cations such as  $\text{Pb}^{2+}$  (1.35 Å) and  $\text{Sr}^{2+}$  (1.13 Å) occurs preferentially in the M(2) positions. The second reason is based on the electronegativity of cation. If an increase in the electronegativity of the cation results in increased covalent character of the bond between the cation and the hydroxyl group (Rajagopal, Dhanabalan, Major, and Kulkarni, 1998). In the case of  $\text{Cd}^{2+}$  (0.97 Å) which is smaller than  $\text{Ca}^{2+}$  (0.99 Å) preferential position for substitution is still the M(2) position because the electronegativity of  $\text{Cd}^{2+}$  (1.7) is higher than that of  $\text{Ca}^{2+}$  (1.0) which favors bonding with the hydroxyl group at the M(2) position.

When studying solid solution materials, Vegard's law behavior confirms the formation of a solid solution by the relationship between composition and unit cell parameters. The law states that unit cell parameters change linearly with composition. When Vegard's law holds over the composition range studied the material is generally assumed to be a solid solution over that range. More detail of Vegard's law is given in the Chapter I (pp. 19-20).

The PHREEQC speciation calculation program is useful for prediction of possible phases in the system based on the equilibrium chemistry of an aqueous solution interacting with solids and gases. Saturation index (SI) calculations from PHREEQC indicate the supersaturation state of an individual phase in the solution. SI is calculated for each phase made up of the ions in the solution as determined by speciation and other solution processes. When  $\text{SI} < 0$  the solution is undersaturated,

when  $SI = 0$  the solution is in equilibrium, and when  $SI > 0$  the solution is supersaturated and precipitation is thermodynamically spontaneous. The PHREEQC program is described further in Chapter I, pp. 25-26.

Previous work (Dungkaew, Saisa-ard, and Haller, 2010) studied the phase characterization and saturation modeling of the calcium phosphate-arsenate apatite system. The study shows that arsenic removal efficiency is increased by adding phosphate to the system. The PHREEQC speciation program was used for simulation of saturated phases in the system, and the results suggest several calcium-arsenate phases are supersaturated in the system even without adding phosphate. However, when phosphate was added, the saturation index of CaHAp was considerably higher than those for arsenate containing phases, implying a considerably higher driving force for nucleation of phosphate containing apatite. The XRD result is consistent with the PHREEQC result and suggests arsenate ions are incorporated into the CaHAp structure as *d*-spacing in the CaHAp materials expand with higher percent arsenic incorporated into the solid products. When composition is plotted versus the *d*-spacing value of the solid products Vegard's law holds showing that the solid products are hydroxyapatite solid solution supporting the hypothesis that solid products can form calcium phosphate-arsenate hydroxyapatite solid solutions. These results support understanding of arsenate removal through calcium phosphate-arsenate precipitation. Therefore, characterization of solid products in the system is concerned.

The current chapter reports a study of Ca-PbHAp materials. Several other studies of Ca-PbHAp materials have been reported (Narasaraju, Singh, and Rao, 1972; Verbeeck, Lassuyt, Heijligers, Driessens, and Vrolijk, 1981; Yasukawa,

Kamiuchi, Yokoyama, and Ishikawa, 2002). However, the characterization of Ca-PbHAp solid product phase with prediction from the PHREEQC program has not been reported. A precipitation method was utilized for preparation of Ca-PbHAp materials in this chapter.

## 3.2 Experimental

### *Reagents*

Reagents for preparation of CaHAp, PbHAp, and Ca-PbHAp

- Diammonium hydrogen phosphate,  $(\text{NH}_4)_2\text{HPO}_4$  (Ajax Finechem, AR grade)
- Calcium nitrate tetrahydrate,  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  (Ajax Finechem, AR grade)
- Lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$  (Ajax Finechem, AR grade)

Reagents for adjusting pH

- Sodium hydroxide, NaOH (Eka Chemicals AB, AR grade)

All solutions in this experiment were prepared from deionized (DI) water.

### *Preparation of apatite material*

CaHAp, PbHAp, and Ca-PbHAp materials were prepared by adding 20 mL of 0.6 M  $(\text{NH}_4)_2\text{HPO}_4$  (pH adjusted to 10 with 1.0 M NaOH) into 20 mL of 1.0 M total metal solutions prepared from  $\text{Pb}(\text{NO}_3)_2$  (natural pH = 6.44) and/or  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  (natural pH = 6.61), by dropwise addition. After addition of the  $(\text{NH}_4)_2\text{HPO}_4$  solution, the suspension was stirred an additional 30 min and filtered. The solid materials were

dried at room temperature for 24 h and then heated at 600 °C for 4 h. The molar ratios of Ca:Pb were controlled as 5Ca, 4Ca:1Pb, 3Ca:2Pb, 2Ca:3Pb, 1Ca:4Pb, and 5Pb.

### ***Characterization***

The precipitate products were characterized by Powder X-ray diffraction using a Bruker Analytical X-ray Systems model D5005 X-ray diffractometer equipped with a Cu K $\alpha$  radiation source operating at 40 kV and 40 mA and the XRD Commander Executable analysis software (Bruker axs, 2011). XRD data were collected in the 2 $\theta$  range 10-60° in steps of 0.02° and scan speed of 0.5 sec/step. Crystal morphologies were observed by scanning electron microscopy using a JSM 6400 electron microscope (JEOL, Japan). A plot of *d*-spacing as a function of composition was prepared to evaluate Vegard's law behavior. PHREEQC program (Parkhurst and Appelo, 1999) was used to calculate ion speciation and saturation indices of potential phases in the system. The database used in this work based on MinteqV4 database (Parkhurst and Appelo, 1999) which is distributed with the PHREEQC program.

### **3.3 Results and discussion**

Morphologies of solid products were observed by SEM as shown in Figure 3.1. Ca<sub>1</sub>Pb<sub>4</sub> shows plate-like crystal morphology (Figure 3.1(d)), while other products show aggregates of powdery products (Figure 3.1(a-c), (e-f)).

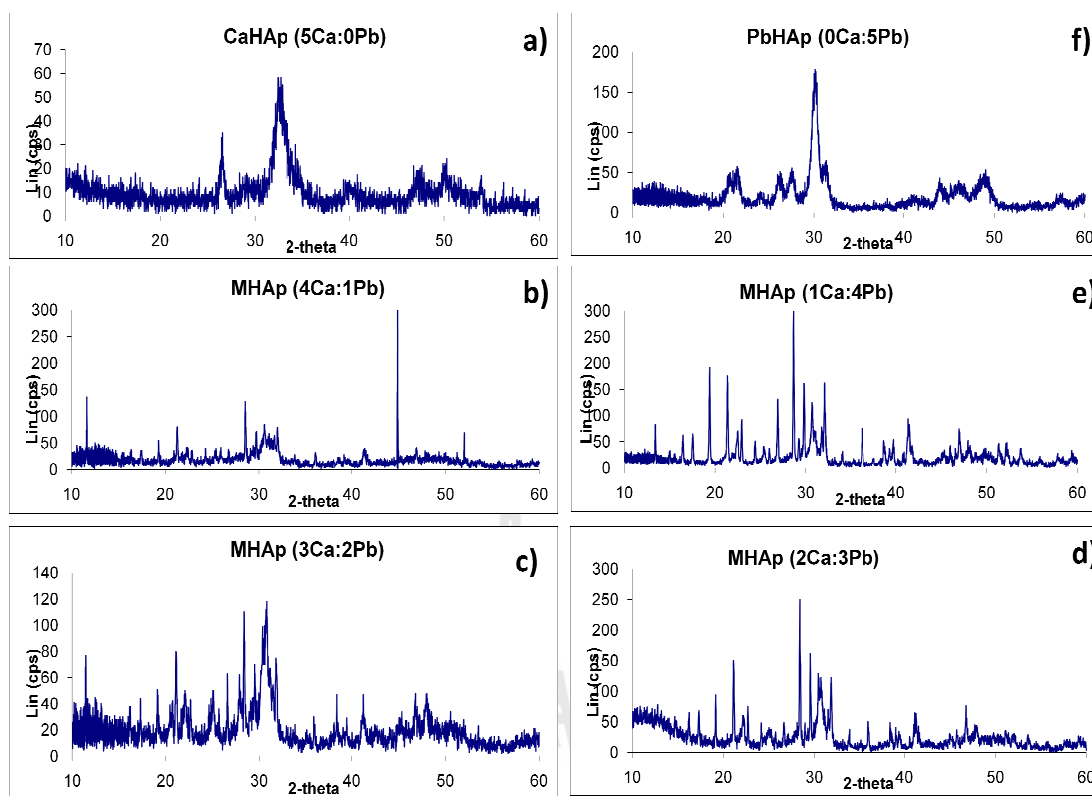

XRD patterns of the products from pure calcium, 5Ca (Figure 3.2(a)) and pure lead, 5Pb (Figure 3.2(f)) match with the XRD peak patterns of CaHAp (JCPDS 3-0742) and PbHAp (JCPDS 1-0924), respectively, in the JCPDS database (Figure 3.3).

These results indicate the solid products are apatite materials. The XRD peak patterns of products from mixing calcium and lead (4Ca:1Pb, 3Ca:2Pb, 2Ca:3Pb, and 1Ca:4Pb) do not match with the apatite phases in the JCPDS database as shown in Figure 3.2(b-e).

**Figure 3.1** SEM images of solid products from precipitation of Ca-PbHAp. Molar ratio of Ca/Pb was varied as a) 5Ca, b) 4Ca:1Pb, c) 3Ca:2Pb, d) 2Ca:3Pb, e) 1Ca:4Pb, and f) 5Pb.

**Figure 3.2** XRD patterns of solid products from precipitation of Ca-PbHAp. Molar ratio of Ca/Pb was varied as a) 5Ca, b) 4Ca:1Pb, c) 3Ca:2Pb, d) 2Ca:3Pb, e) 1Ca:4Pb, and f) 5Pb.

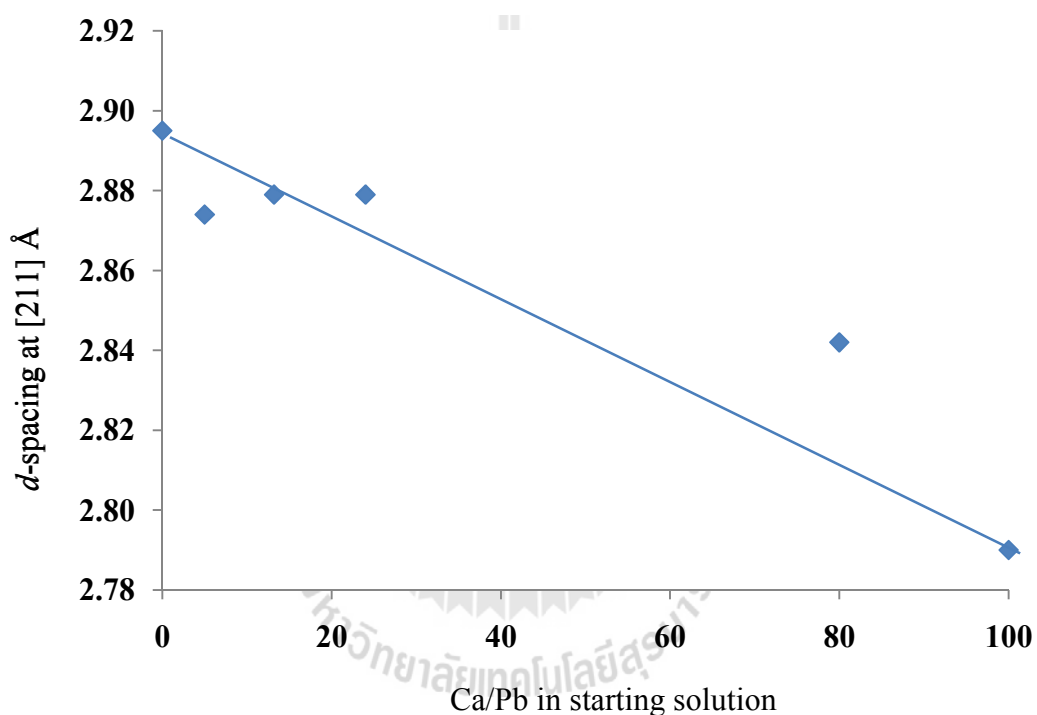

**Figure 3.3** XRD patterns of  $\text{Ca}_0\text{Pb}_5$  compared with PbHAp in the JCPDS database.

Apatite materials from the precipitation method exhibit pure apatite phase at high temperature (LeGeros, 1991), therefore, all solid products were heated at 600 °C for 4 h and their phases characterized by XRD. After heating, the XRD result of 5Ca shows sharper peak of CaHAp phase (Figure 3.4(a)), however, the XRD peaks of other products (Figure 3.4(b-f)) show higher intensity and sharper peak but do not match with CaHAp or PbHAp peak pattern in the JCPDS database and several extra peaks appear. These results could suggest multiple product phases occur in the system.

**Figure 3.4** XRD patterns of solid products from precipitation of Ca-PbHAp after heating at 600 °C for 4 h. Molar ratio of Ca/Pb was varied as a) 5Ca, b) 4Ca:1Pb, c) 3Ca:2Pb, d) 2Ca:3Pb, e) 1Ca:4Pb, and f) 5Pb.

The position of the dominant [211] peak near  $30^\circ 2\theta$  from these solid products was plotted as a function of composition to study Vegard's law behavior to explore the characteristic of solid solution material. The correlation of composition and  $d$ -spacing of the [211] peak is shown in Figure 3.5. Result indicates these products are not Ca-PbHAp solid solution because the graph does not follow Vegard's law.

**Figure 3.5** Correlation between calcium to lead ratio in starting solutions and the expansion of  $d$ -spacing in solid products.

Several possible phases (positive SI value) are predicted from the PHREEQC calculation as shown in Table 3.1. These results are consistent with the XRD results, suggesting multiple products could be formed in the system.

**Table 3.1** Saturation index values of Ca-P and Pb-P phases predicted from PHREEQC program.

Phase	SI of solid product					
	Ca <sub>5</sub> Pb <sub>0</sub>	Ca <sub>4</sub> Pb <sub>1</sub>	Ca <sub>3</sub> Pb <sub>2</sub>	Ca <sub>2</sub> Pb <sub>3</sub>	Ca <sub>1</sub> Pb <sub>4</sub>	Ca <sub>0</sub> Pb <sub>5</sub>
Ca <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	8.28	7.41	6.46	5.34	4.31	-
Ca <sub>4</sub> H(PO <sub>4</sub> ) <sub>3</sub> ·3H <sub>2</sub> O	9.56	8.40	7.12	5.62	4.25	-
CaHPO <sub>4</sub>	2.54	2.25	1.94	1.57	1.23	-
CaHPO <sub>4</sub> ·2H <sub>2</sub> O	2.19	1.90	1.58	1.21	0.86	-
Ca <sub>5</sub> (PO <sub>4</sub> ) <sub>3</sub> OH	19.72	18.26	16.66	14.78	13.07	-
Pb <sub>5</sub> (PO <sub>4</sub> ) <sub>3</sub> OH	-	15.13	14.70	14.09	12.22	12.60
Pb <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	-	9.04	8.78	8.42	7.30	7.54
PbHPO <sub>4</sub>	-	2.45	2.37	2.25	1.88	1.97

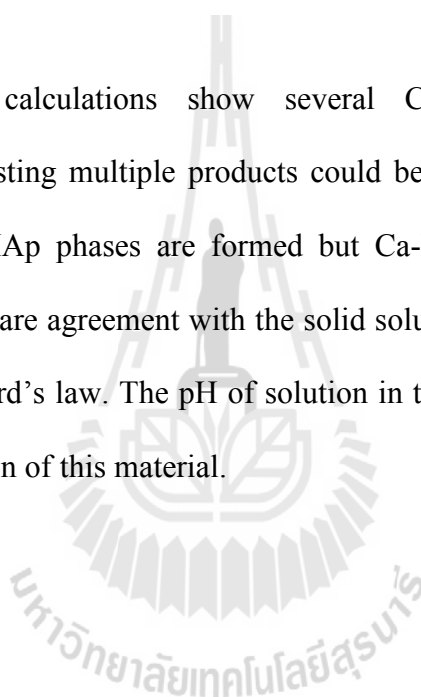

The SI values of PbHAp and CaHAp are considerably higher than other phases, implying a higher driving force for nucleation of PbHAp and CaHAp phases resulting in reduction of the ion concentrations such that the Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, PbHPO<sub>4</sub>, Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, CaHPO<sub>4</sub>, CaHPO<sub>4</sub>·2H<sub>2</sub>O, and Ca<sub>4</sub>H(PO<sub>4</sub>)<sub>3</sub>·3H<sub>2</sub>O phases were not formed. Several phases are predicted by PHREEQC. However, these phases do not appear clearly in the XRD pattern because they are minor products or do not form.

This work obtained unexpected results. It may cause from the pH of the solution is not suitable for the Ca-PbHAp formation. The Ca-PbHAp has been obtained at pH 12 (Verbeeck, Lassuyt, Heijligers, Driessens, and Vrolijk, 1981). However, this material also has been reported the formation at low pH of 3.92-5.22 (Yasukawa, Kamiuchi, Yokoyama, and Ishikawa, 2002) but the pH in this work is much lower than that (pH 2-3). This because we cannot adjust pH of metal solutions

in the experimental step due to the rapidly precipitate of  $\text{Pb}(\text{NO}_3)_2$  with  $\text{NaOH}$  to form  $\text{Pb}_6\text{O}_3(\text{NO}_3)_2(\text{OH})_4$  (XRD peaks as shown in Appendix B, pp. 116). Adjusting pH of  $\text{Pb}(\text{NO}_3)_2$  with  $\text{C}_2\text{H}_4(\text{NH}_2)_2$  also shows the precipitation of solid phase ( $\text{Pb}(\text{OH})_2$ ) in the system (Narasaraju, Singh, and Lao, 1972). Therefore, the pH of solution is may an important factor for the formation of this material.

### 3.4 Conclusions

PHREEQC calculations show several Ca-P and Pb-P phases are supersaturated, suggesting multiple products could be formed. XRD results suggest the CaHAp and PbHAp phases are formed but Ca-PbHAp is not formed in this system. These results are agreement with the solid solution study that show the graph does not follow Vegard's law. The pH of solution in the system is may an important factor for the formation of this material.

# CHAPTER IV

## GEL CRYSTALLIZATION OF LEAD-PHOSPHATE MATERIALS<sup>1</sup>

### 4.1 Introduction

Gel crystallization is an interesting technique because of its simplicity and effectiveness in growing single crystals, especially of low solubility materials. This technique has been applied to the study of crystal formation of materials occurring in the human-related system, such as cholesterol stones, gall stones, and urinary calculi. Furthermore, it provides an ideal technique to study crystal deposition diseases, which could lead to better understanding of the cause of disease (Kalkura and Natarajan, 2010; Ramachandran and Natarajan, 2002; Girija, Yokogawa, and Nagata, 2004).

The two methods used most often to grow crystals in gel media are single diffusion and double diffusion methods (Santhana Raghavan and Ramasamy, 2000)

#### *Single diffusion method*

This method is a suitable method for highly soluble compounds which do not react chemically with the gel medium. The “inner reactant” is set with the gel

---

<sup>1</sup>This work has been accepted for publication in the Engineering Journal (Saisa-ard and Haller, 2012).

medium in the bottom layer of the container. After gel setting, the other reactant solution called the “outer reactant”, is poured on top of the gel layer. The chemical reaction occurs as the two reactants meet and crystals are obtained. The setting of this method is shown in Figure 4.1.

**Figure 4.1** Schematic illustration of the single diffusion method.

### ***Double diffusion method***

This method is more suitable for insoluble compounds or materials that react with the gel medium. The reactant solutions are separated in the side arms of a U-tube (Figure 4.2) by placing the two reactant solutions on top of the gel medium in the opposing tubes after gel setting. Reactants diffuse through the gel medium and the reaction occurs at the point they meet.

**Figure 4.2** Schematic illustration of the double diffusion method.

### ***Importance of gel technique***

Growth of crystals in gel is a good technique not only for preparation of large single crystals but also for control of defect formation. If the formation of crystals is not perfect, it leads to imperfect determination of the physical properties such as optical, electrical, and mechanical properties of the crystals (Santhana Raghavan and Ramasamy, 2000). Some important features of this technique are listed below:

- The rate of reaction and nucleation can be controlled by varying the density of the gel medium.
- The gel medium holds the crystals in fixed positions, minimizing external disturbances.
- Fewer defects occur during the formation of crystals because of the slow controlled rate of reaction.
- The crystals can be harvested easily

- The growth of crystals at each stage can be observed in the glass reaction vessel.

### ***Crystallization of lead-phosphate materials in gel systems***

Lead-phosphate (Pb-P) materials are interesting materials due to their properties. Lead hydrogen phosphate ( $\text{PbHPO}_4$ ) and lead nitrate phosphate ( $\text{Pb}_2(\text{NO}_3)(\text{PO}_4)$ ) show dielectric, piezoelectric, and optical properties which are useful in transducers and memory devices. Lead phosphate ( $\text{Pb}_3(\text{PO}_4)_2$ ) is known as a ferroelastic material with a phase transition near 180 °C. The phase changes from  $\alpha$ -phase ( $C2/c$  ferroelastic phase) below 180 °C to  $\beta$ -phase ( $R\bar{3}m$  prototypic phase) above 180 °C (Guimaraes, 1979; Decker, Petersen, and Debray, 1979). Several researchers have reported growth of  $\text{PbHPO}_4$  and  $\text{Pb}_2(\text{NO}_3)(\text{PO}_4)$  in silica hydrogel, tetramethoxysilane gel, cross-linked polyacrylamide gel, agar gel, and gelatin, (Desai and Ramana, 1990; Desai and Ramana, 1998; Robert and Lefauchaux, 1988; Březina, Havránková, and Dušek, 1976). The appearance of small crystals of lead hydroxyapatite,  $\text{Pb}_5(\text{PO}_4)_3(\text{OH})$ , (PbHAp), in the gel layers or on the surfaces of other Pb-P products has not been reported. PbHAp is a material of biological interest because of the similarity to calcium hydroxyapatite,  $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$ , (CaHAp), the dominant component in mammalian hard tissues such as bones and teeth; about 69 wt % and 95 wt %, respectively (LeGeros, 1991). The relationship of PbHAp to CaHAp and its link to bone diseases like osteoporosis make the crystallization and growth of these materials of interest.

This chapter presents results of Pb-P material growth in agarose gel with varied density of the gel medium. The PHREEQC speciation program (Parkhurst and

Appelo, 1999) is used in this work to calculate possible phases in the Pb-P system supporting formation of PbHAp and other Pb-P phases. The relationship between synthesis conditions and crystal phases of products, including the formation of PbHAp, are discussed based on the results obtained.

## 4.2 Experimental

### *Reagents*

Reagents for preparation of gel medium

- Agarose powder (Vivantis, molecular biology grade)

Reagents for preparation of lead phosphate material

- Diammonium hydrogen phosphate,  $(\text{NH}_4)_2\text{HPO}_4$   
(Ajax Finechem, AR grade)
- Lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$  (Ajax Finechem, AR grade)

Reagents for adjusting pH

- Sodium hydroxide, NaOH (Eka Chemicals AB, AR grade)

All solutions in this experiment were prepared from deionized water.

### *Sample preparation*

Diffusion of two soluble compounds through the agarose gel was set for the crystal growth in tubes as illustrated schematically in Figure 4.3. Crystalline products are obtained in the gel when the two reactants meet.  $(\text{NH}_4)_2\text{HPO}_4$  and  $\text{Pb}(\text{NO}_3)_2$  were used as  $\text{PO}_4^{3-}$  and  $\text{Pb}^{2+}$  sources, respectively. Varied densities of phosphate gel (1.0, 1.3, 1.5, 1.7, and 2.0 % w/v of agarose) were prepared by dissolving agarose powder in 20 mL water with stirring for 10 min at 100 °C to give clear solutions.

Crystallization experiments were set in small test tubes (1.5 x 10 cm) by adding 3.0 mL of the appropriate hot gel solution to 2.5 mL of warm 0.6 M phosphate solution, adjusting pH to 10 with NaOH, and allowing the mixture to stand 20 min to cool to room temperature to gel. A second layer of pure gel (1.0, 1.5, and 2.0 % w/v) was created by adding 1.5 mL of pure gel solution on top of the  $\text{PO}_4^{3-}$  gel layer and allowing 20 min to set the pure gel layer, after which 2.5 mL of 1.0 M lead nitrate solution at natural pH was added on top of the gel layers. All reactions were kept at room temperature for two weeks.  $\text{CO}_2$  was purged from the lead solution by passing Ar gas through the solution for 5 min before transfer.

After two weeks the remaining solution was removed and the gel layers separated. Each gel layer was warmed to melt the gel and the solid products filtered off. The three solutions were combined and pH measured. The solids were washed with cold water and dried at 100 °C for 24 h.

**Figure 4.3** Experimental set up for gel crystallization of lead-phosphate phases.

### ***Characterization***

Crystal morphologies were observed by optical microscopy using an Olympus SZ40 microscope (Olympus, Japan) and scanning electron microscopy (SEM) using a JSM 6400 electron microscope (JEOL, Japan). IR spectra were acquired on a Perkin-Elmer model Spectrum GX Fourier transform infrared spectrophotometer (FTIR) in wave number range  $400\text{-}4000\text{ cm}^{-1}$  from KBr pellets. Powder X-ray diffraction (XRD) scans were used for phase identification,  $2\theta$  range  $10\text{-}60^\circ$  using a D5005 diffractometer equipped with a  $\text{Cu K}\alpha$  X-ray source operating at 40 kV and 40 mA and the XRD Commander Executable analysis software (Bruker axs, 2011). The speciation program, PHREEQC V2 with the MinteqV4 database (Parkhurst and Appelo, 1999) was used to calculate potential phase formation in the system assuming complete instantaneous mixing of the reactants.

### **4.3 Results and discussion**

Crystalline products were obtained inside both pure and  $\text{PO}_4^{3-}$  gel layers for all reactions as observed after two weeks reaction time. A typical result (density of phosphate and pure gel of 1.7 and 2.0 % w/v, respectively) is shown in Figure 4.4.

**Figure 4.4** Crystalline products in pure and  $\text{PO}_4^{3-}$  gel layers for a typical reaction.

Microscopic crystalline products were accompanied by a decrease in pH to 3 for all reactions studied. Their morphologies were observed by optical microscopy and SEM. The crystal morphologies of products formed in the pure gel and  $\text{PO}_4^{3-}$  gel layers are illustrated in Figure. 4.5 and 4.6, respectively.

**Figure 4.5** Optical and SEM images of products formed in the pure gel layer. i) Optical (2.5X) and ii) SEM images. Density of pure gel layer is 2.0 % w/v but different density of  $\text{PO}_4^{3-}$  gel: (a) 1.0, (b) 1.3, (c) 1.5, (d) 1.7, (e) 2.0 % w/v.

**Figure 4.6** Optical and SEM images of products formed in the  $\text{PO}_4^{3-}$  gel layer. i) Optical (2.5X) and ii) SEM images. Density of pure gel layer is 2.0 % w/v but different density of  $\text{PO}_4^{3-}$  gel: (a) 1.0, (b) 1.3, (c) 1.5, (d) 1.7, (e) 2.0 % w/v.

Products appear as aggregates under optical microscopy in the pure gel layer (Figure 4.5a(i)-e(i)) and in the  $\text{PO}_4^{3-}$  gel layer (Figure 4.6f(i)-j(i)). Individual crystallites from the pure gel layer show equant habit (Figure 4.5a(ii)-e(ii)), and those from the  $\text{PO}_4^{3-}$  gel layer show plate-like habit (Figure 4.6f(ii)-j(ii)) as seen in low magnification SEM images.

Needle-like crystals with dimension about  $2.5 \times 10 \mu\text{m}$  are deposited on the surfaces of crystal products formed in the pure gel layer as can be seen in SEM images at higher magnification as shown in Figure 4.7. These crystals have similar morphology to those reported for PbHAp (Mavropoulos, Rocha, Moreira, Rossi, and Soares, 2004). This observation further confirms that multiple product phases occur in this system, and indicates that they occur in sequential fashion. These small crystallites observed only in the pure gel layer occur for all the different densities of  $\text{PO}_4^{3-}$  gel layer.

IR wave number and assignments for the products are given in Table 4.1. All products give almost identical spectra that show characteristic bands of  $\text{PO}_4^{3-}$  group; bands in the regions  $955\text{-}1046 \text{ cm}^{-1}$ ,  $923\text{-}924 \text{ cm}^{-1}$ , and  $519\text{-}601 \text{ cm}^{-1}$  reveal the asymmetric P–O stretching ( $\nu_3$ ), symmetric P–O stretching ( $\nu_1$ ), and O–P–O bending ( $\nu_4$ ), respectively.

An ideal  $\text{PO}_4^{3-}$  anion has tetrahedral point symmetry. Only absorptions corresponding to the  $\nu_3$  ( $955\text{-}1046 \text{ cm}^{-1}$ ) and  $\nu_4$  ( $519\text{-}601 \text{ cm}^{-1}$ ) vibrations should be observed. The  $\nu_1$  ( $923\text{-}924 \text{ cm}^{-1}$ ) and  $\nu_2$  ( $388\text{-}449 \text{ cm}^{-1}$ ) vibrations would be allowed in lower symmetry groups. The appearance of  $\nu_1$  and  $\nu_2$  in the IR spectra of both

products from pure and  $\text{PO}_4^{3-}$  gel layers indicates the lower symmetry of  $\text{PO}_4^{3-}$  in the structure (Bhatnagar, 1970; Ternane, Ferid, Trabelsi-Ayedi, and Piriou, 1999).

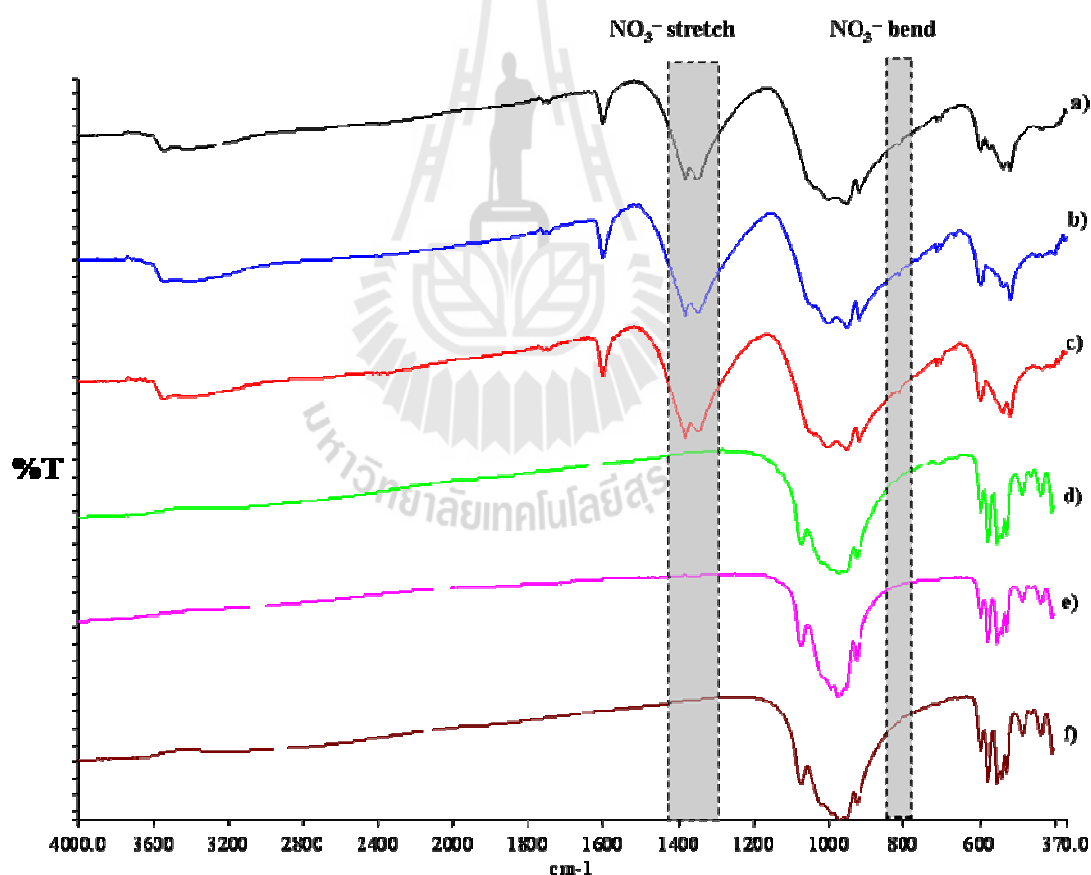

**Figure 4.7** SEM images of products obtained in the pure gel layer. Density of pure gel layer is 2.0 % w/v but different density of  $\text{PO}_4^{3-}$  gel: (a) 1.0, (b) 1.3, (c) 1.5, (d) 1.7, (e) 2.0 % w/v.

**Table 4.1** IR frequencies and vibrational assignments of crystal products from pure and phosphate gel layers.

Crystal in the pure gel layer ( $\text{cm}^{-1}$ )	Crystal in the $\text{PO}_4^{3-}$ gel layer ( $\text{cm}^{-1}$ )	Assignment
~3555 w, b		$(\nu_1 + \nu_3)$ $\text{H}_2\text{O}$ stretch
~1604 m		$\nu_2\text{H}_2\text{O}$ bend
1384 vs	~1100 s,b	$(\nu_1 + \nu_3)$ $\text{NO}_3$ stretch
1348 vs		
1046 sh		$\nu_3\text{PO}_4$ stretch
1004-1005 vs		
955-956 vs		
923-924 vs		$\nu_1\text{PO}_4$ , $\nu_1\text{HPO}_4$ stretch
813-814 vw		$\nu_2\text{NO}_3$ bend
715-716 vw		$\text{H}_2\text{O}$ libration
705-706 vw		
600-601 m		$\nu_4\text{PO}_4$ bend
539 m	548 s	
519-520 m		
398 sh	449 w	$\nu_2\text{PO}_4$ bend, $\nu_2\text{HPO}_4$ bend
	388 vw	

Abbreviations: w = weak, m = medium, s = strong, v = very, sh = shoulder, b = broad. Assignments:  $\nu_1$  = symmetric stretching,  $\nu_2$  = bending,  $\nu_3$  = asymmetric stretching,  $\nu_4$  = bending.

Water bending mode ( $1604\text{ cm}^{-1}$ ) and O–H stretching mode ( $3555\text{ cm}^{-1}$ ) are observed for the products obtained inside the pure gel layer but not for products obtained inside the  $\text{PO}_4^{3-}$  gel layer. IR spectra of products formed in the pure gel layer also show nitrate bands at  $1348\text{--}1384$  and  $813\text{--}814\text{ cm}^{-1}$  which, along with the water bands, disappear after heating at  $600\text{ }^\circ\text{C}$  (Figure 4.8). These bands may be due to residual nitrate from starting compound as suggested in previous work (Stepuk, Veresov, Putlyayev, and Tret'yakov, 2007). It is also possible that the nitrate and water bands represent an additional unidentified phase.

**Figure 4.8** IR spectra of products formed in the pure gel layer. (a-c) before heating and (d-f) after heating at  $600\text{ }^\circ\text{C}$ . Density of pure gel layer is  $2.0\text{ }\%$  w/v but different density of  $\text{PO}_4^{3-}$  gel: (a, d)  $1.0$ , (b,e)  $1.5$ , (c, f)  $2.0\text{ }\%$  w/v.

Products obtained in the pure gel layer exhibit a mixture of three phases including PbHAp (JCPDS 1-0924), PbHPO<sub>4</sub> (JCPDS 6-0274), and Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> (JCPDS 13-0278) as shown in Figure 4.9 while products formed in the PO<sub>4</sub><sup>3-</sup> gel layer show only peaks due to PbHPO<sub>4</sub> and Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> (Figure 4.10).

Peaks due to PbHAp and Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> phases are difficult to see because they are minor products. Small needle-like PbHAp crystals on the surface of products separated from the pure gel layer can be seen in the SEM images in Figure 4.7.

**Figure 4.9** XRD patterns of products obtained in the pure gel layer. Density of pure gel layer is 2.0 % w/v but different density of PO<sub>4</sub><sup>3-</sup> gel: (a) 1.0, (b) 1.3, (c) 1.5, (d) 1.7, and (e) 2.0 % w/v; (□) PbHPO<sub>4</sub>, (◇) Pb<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, and (○) PbHAp.

**Figure 4.10** XRD patterns of products obtained in the  $\text{PO}_4^{3-}$  gel layer. Density of pure gel layer is 2.0 % w/v but different density of  $\text{PO}_4^{3-}$  gel: (a) 1.0, (b) 1.3, (c) 1.5, (d) 1.7, and (e) 2.0 % w/v; (□)  $\text{PbHPO}_4$ , (◇)  $\text{Pb}_3(\text{PO}_4)_2$ , and (○)  $\text{PbHAp}$ .

These results are consistent with predictions (assuming instantaneous mixing of all reactants in an aqueous solution) obtained from the PHREEQC program that calculates saturation indices based on aqueous solution activities for all species involved. A description of the PHREEQC program methodology is given in the Chapter I (pp. 25-26).

Calculation of saturation index (SI) requires detailed knowledge of the speciation of phosphate, lead compounds, and other related ions in the system.

Speciation of relevant phosphate and lead compounds in the system is given in Table 4.2.

**Table 4.2** Acid dissociation constants ( $K_a$ ) for  $H_3PO_4$  speciation, and solubility product constants ( $K_{sp}$ ) and SI for various lead compounds.

<b><math>H_3PO_4</math> speciation</b>	<b><math>K_a</math><sup>1</sup></b>		
$H_3PO_4 \rightleftharpoons H_2PO_4^- + H^+$	$6.309 \times 10^{-3}$

<sup>2</sup>Values from minteq.v4 database in reference (Parkhurst and Appelo, 1999)

<sup>3</sup>This work for the system described in the text.

An initial pH = 10 in the  $PO_4^{3-}$  gel and initial pH of 6 in the 1 M  $Pb(NO_3)_2$  solution, imply a pH gradient through the “pure” gel layer from 10 to 6 as the reactants diffuse together (if all three layers were instantaneously mixed as an aqueous solution the pH would be 8). At pH = 10 the phosphate speciation (Figure 4.11) predicts a small  $PO_4^{3-}$  concentration and  $HPO_4^{2-}$  as the dominant species. At pH

= 6  $\text{H}_2\text{PO}_4^-$  is the dominant species with only a few percent  $\text{HPO}_4^{2-}$  and even less  $\text{PO}_4^{3-}$ . PHREEQC calculations based on the total initial concentrations of species in all layers combined indicate that  $\text{PbHPO}_4$ ,  $\text{Pb}_3(\text{PO}_4)_2$ , and  $\text{PbHAp}$  would be supersaturated (pH = 8, and SI = 2.08, 7.88, and 13.17, respectively). The larger SI for the  $\text{PO}_4^{3-}$  containing species in spite of the low  $\text{PO}_4^{3-}$  concentration is a result of their solubilities being considerably lower than that of the  $\text{HPO}_4^{2-}$  containing species, and suggests they may nucleate first.

**Figure 4.11** pH variation of ionic concentrations in the triprotic equilibrium for phosphoric acid solutions.

As phosphate ion is removed from the gel by precipitation, the speciation equilibrium will convert  $\text{HPO}_4^{2-}$  to  $\text{H}^+$  and  $\text{PO}_4^{3-}$ , lowering the pH and at the same time adjusting the relative ion concentrations to favor  $\text{HPO}_4^{2-}$  until the hydrogen

phosphate species nucleates. Of course if the hydrogen phosphate species nucleates first, the opposite logic applies until the phosphate compounds nucleate, but this would require two separate phosphate compounds to reach supersaturation and nucleate, which seems less probable. As growth proceeds, the trajectory of the pH will be determined by the relative sequestering of either or both phosphate or hydrogen phosphate in the solid phases

At the beginning of the experiment, the pH gradient in the pure gel layer is predisposed to higher pH by the procedure of placing the pure gel solution on the phosphate gel layer. Diffusion of ions from the phosphate layer will commence immediately, and a small amount of the phosphate gel will dissolve before the “pure” gel sets. Both effects favor increased  $\text{PO}_4^{3-}$  ion concentration near the lead solution, favouring initial precipitation of the phosphate phases in the pure gel layer. The presence of PbHAp in the pure gel layer but not in the phosphate layer can be understood based on the higher  $\text{Pb}^{2+}:\text{PO}_4^{3-}$  ratio (5:3 vs 3:2) required for the PbHAp phase relative to the  $\text{Pb}_3(\text{PO}_4)_2$  phase.

#### 4.4 Conclusions

Speciation calculations indicate the possibility of forming mixed phases of  $\text{PbHPO}_4$ ,  $\text{Pb}_3(\text{PO}_4)_2$ , and PbHAp in this system. XRD results confirm their formation, including the previously unreported gel precipitation of PbHAp. IR spectra of the crystalline products exhibit  $\nu_1$  and  $\nu_2$  vibrational bands indicating the point symmetry of  $\text{PO}_4^{3-}$  is lower than tetrahedral. Formation of the microscopic crystalline products was accompanied by a decrease in pH from 8 (theoretical for all layers mixed) to 3 for all reactions studied, consistent with  $\text{PbHPO}_4$  being the major product. Formation

of  $\text{PbHPO}_4$ ,  $\text{Pb}_3(\text{PO}_4)_2$ , and  $\text{PbHAp}$  phases with changing pH may be an important key for better understanding of the precipitation of biological hard tissues and the environmental geology of lead and phosphorus.

# CHAPTER V

## CRYSTALLIZATION OF LEAD HYDROXYAPATITE

### BY USING REFLUX METHOD<sup>1</sup>

#### 5.1 Introduction

##### *Reflux method*

Reflux allows a mixture to be heated constantly without monitoring and without loss of material. A reflux vessel such as a round bottom flask is attached to a water cooled condenser which prevents vapors from escaping during the heating process.

The advantage of this technique is that it can be left for a long period of time without the need to add more solvent or fear of the reaction vessel boiling dry as any vapor is immediately condensed and returned to the reaction vessel. In addition as a given solvent will always boil at a certain temperature, one can be sure that the reaction will proceed at a constant temperature. By careful choice of solvent, one can control the temperature within a very narrow range. The constant boiling action also serves to continuously mix the solution, although a magnetic stirring rod mechanism is often used to assist achievement of a uniform solution. This technique is useful for performing chemical reactions under controlled conditions that require substantial time for completion.

---

<sup>1</sup>This work has been submitted for publication (Saisa-ard and Haller, 2012).

***Crystallization of lead hydroxyapatite by calcium hydroxyapatite dissolution***

Calcium hydroxyapatite,  $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$ , (CaHAp) is of interest because of its occurrence in biological hard tissues such as bones and teeth (LeGeros, 1991). Divalent cations such as  $\text{Pb}^{2+}$  can substitute for  $\text{Ca}^{2+}$  ions in the CaHAp structure. Complete substitution of  $\text{Pb}^{2+}$  ions into CaHAp structure results in isostructural lead hydroxyapatite,  $\text{Pb}_5(\text{PO}_4)_3(\text{OH})$ , (PbHAp). PbHAp has been studied including its structure (Brückner, Lusvardi, Menabue, and Saladini, 1995; Kim, Fenton, Hunter, and Kennedy, 2000) and solubility properties (Valsami-Jones, Ragnarsdottir, Putnis, Bosbach, and Kemp, 1998) partly because the accumulation of  $\text{Pb}^{2+}$  in bones can lead to bone diseases like osteoporosis. Therefore, the relationship between CaHAp and PbHAp in terms of their structure and properties might be an important key for understanding the accumulation of  $\text{Pb}^{2+}$  in bone. Studies of  $\text{Pb}^{2+}$  immobilization by synthetic CaHAp have been reported (Mavropoulos, Rossi, and Costa, 2002; Mavropoulos, Rocha, Moreira, Rossi, and Soares, 2004), and show dissolution of CaHAp in  $\text{Pb}^{2+}$  solution and then concomitant crystallization of PbHAp in the system. The mechanism in acidic conditions has been proposed (Dong, Zhu, Qiu, and Zhao, 2010) as

Dissolution:

Precipitation:

This chapter reports preparation of larger PbHAp crystals for studies of their structure and solubility properties. A reflux method was used to increase CaHAp dissolution rate, and thus, PbHAp crystallization rate in the system. The relationship between reaction times and crystal morphologies of products is discussed.

## 5.2 Experimental

### *Reagents*

Reagents for preparation of CaHAp and PbHAp materials

- Diammonium hydrogen phosphate,  $(\text{NH}_4)_2\text{HPO}_4$  (Ajax Finechem, AR grade)
- Calcium nitrate tetrahydrate,  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  (Ajax Finechem, AR grade)
- Lead(II) nitrate,  $\text{Pb}(\text{NO}_3)_2$  (Ajax Finechem, AR grade)

Reagents for adjusting pH

- Sodium hydroxide, NaOH (Eka Chemicals AB, AR grade)

All solutions in this experiment were prepared from deionized (DI) water.

### *Preparation of CaHAp material*

CaHAp was prepared by dropwise addition of 100 mL of 0.6 M  $(\text{NH}_4)_2\text{HPO}_4$  solution into 100 mL of 1.0 M calcium nitrate solution prepared from  $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$ , while stirring at room temperature and maintaining pH of the solution at 11 with 1.0 M NaOH. After addition of the phosphate solution, the suspension was stirred continuously 30 min. The precipitate was separated by filtration, washed with water three times, and dried at 100 °C for 24 h.

### ***Crystallization of PbHAp by reflux method***

Ground CaHAp, 0.2 g, was added into 80 mL of 917 mg/L  $\text{Pb}^{2+}$  solution (0.1172 g of  $\text{Pb}(\text{NO}_3)_2$ ) and refluxed for 24 h or 48 h. The precipitates were separated by filtration, washed with water three times, and dried at 100 °C for 24 h.

### ***Characterization***

Crystal morphologies were observed by scanning electron microscopy (SEM) using a JSM 6400 electron microscope (JEOL, Japan) equipped with energy dispersive X-ray fluorescence (EDX). IR spectra were acquired on a Perkin-Elmer model Spectrum GX Fourier transform infrared spectrophotometer (FTIR) in wavenumber range 400-4000  $\text{cm}^{-1}$  from KBr pellets. Powder X-ray diffraction (XRD) scans were acquired for the  $2\theta$  range 10-55° on a Bruker axis D5005 diffractometer equipped with a  $\text{Cu K}\alpha$  X-ray source operating at 40 kV and 40 mA, and the XRD Commander Executable analysis software (Bruker axis, 2011) for phase identification of products.

## **5.3 Results and discussion**

The SEM images of CaHAp before and after refluxing are shown in Figure 5.1. Crystalline product after refluxing for 24 h exhibits needle-like crystal morphology (Figure 5.1b), while crystalline product after refluxing for 48 h shows hexagonal-rod crystal morphology (Figure 5.1c). The product crystal size increased with increasing reaction time; the largest crystal size is about 10 x 10 x 40  $\mu\text{m}$ .

**Figure 5.1** SEM images of CaHAp. a) Before refluxing, and after refluxing in  $\text{Pb}^{2+}$  solution (917 mg/L) for b) 24 h and c) 48 h.

The EDX spectrum of CaHAp substrate (Figure 5.2a) shows high intensity Ca peaks with calcium to phosphorous ratio of about 5:3 as expected for CaHAp. The EDX spectrum of the crystalline products after refluxing 24 h in lead solution show

high intensity Pb peaks with lead to phosphorous ratio of 5:3 as expected for PbHAp (Figure 5.2b). The Pb peaks of the EDX spectrum of product after 24 h reflux are indistinguishable from Figure 5.2b. Low intensity Ca peaks are also observed in both product spectra, consistent with CaHAp impurity due to the growth substrate. This result is consistent with the XRD result that shows mixed phases of CaHAp and PbHAp.

**Figure 5.2** EDX spectra of a) CaHAp substrate before refluxing and b) products after refluxing in  $\text{Pb}^{2+}$  solution (917 mg/L) for 24 h.

PbHAp and CaHAp phases were identified after 24 h and 48 h of reaction and the results are shown in Figure 5.3. XRD patterns of products after refluxing show mixed phases containing PbHAp (JCPDS 08-0259) and CaHAp (JCPDS 09-0432) due to difficulty in separating the PbHAp from the CaHAp substrate. The presence of PbHAp after 24 h is confirmed by peaks corresponding to PbHAp in the JCPDS database (International Center for Diffraction Data, 2004). Needle-like crystals of this phase were observed by SEM (Figure 5.1b) on the surface of the CaHAp substrate. After 48 h, the XRD pattern of the product clearly shows the PbHAp phase as the major phase with the intensity of PbHAp peaks considerably increased. This result indicates that the phase formation of PbHAp increased with increased reaction time in agreement with previous work (Mavropoulos, Rossi, and Costa, 2002). PbHAp crystal product is present as hexagonal-rod shaped crystals as shown in Figure 5.1c.

**Figure 5.3** XRD patterns of products after refluxing in  $\text{Pb}^{2+}$  solution (917 mg/L) for 24 h and 48 h.

IR spectra of CaHAp and products (Figure 5.4) show  $\text{PO}_4^{3-}$  vibrational bands in the 961-1092  $\text{cm}^{-1}$  and 562-632  $\text{cm}^{-1}$  regions corresponding to P–O stretching and O–P–O bending modes, respectively. Water O–H stretching vibrational bands are present at about 3468  $\text{cm}^{-1}$  in the CaHAp spectrum and 3571  $\text{cm}^{-1}$  in the product spectra. A broad band in the 3000-3700  $\text{cm}^{-1}$  region and a weak peak at 1639  $\text{cm}^{-1}$  in the CaHAp spectrum consistent with O–H stretching and H–O–H bending of water. The same spectrum also exhibits the nitrate stretching noted in a previous chapter in the 1348-1384 and 813-814  $\text{cm}^{-1}$  regions. The IR spectrum of CaHAp shows bands of  $\text{NO}_3^-$  stretching at 1384  $\text{cm}^{-1}$  and  $\text{NO}_3^-$  bending at 873  $\text{cm}^{-1}$  in agreement with previous work (Stepuk, Veresov, Putlyaev, and Tret'yakov, 2007). The nitrate may come from the incorporation of residual nitrate from starting compound. The adventitious ion appears to be a minor impurity that does not appear to carry over into the PbHAp product crystals. As such, further attempts to identify it were not carried out.

**Figure 5.4** IR spectra of CaHAp before refluxing and the products after refluxing in  $\text{Pb}^{2+}$  solution (917 mg/L) for 24 h and 48 h.

## 5.4 Conclusions

The reflux method of CaHAp dissolution to provide phosphate anion in the presence of lead cation succeeds for producing larger sized crystals of the less soluble PbHAp from the aqueous solution. Product crystal size increased with increasing reaction time. EDX results are consistent with the XRD results and show mixed phases of CaHAp and PbHAp due to difficulty in separating the PbHAp from the CaHAp substrate. IR results indicate the incorporation of nitrate in the CaHAp substrate, however, this ion does not appear to carry over into the PbHAp product crystals. As such, further attempts to identify it were not carried out.

## CHAPTER VI

### CONCLUSIONS

Apatite and related materials including calcium hydroxyapatite (CaHAp), lead hydroxyapatite (PbHAp), and other calcium-phosphate, lead-phosphate, and calcium-lead-phosphate materials were studied in this work. Precipitation, gel crystallization, and reflux methods were utilized to prepare apatite and related materials. Bond valence calculations were analyzed for the published PbHAp structure. The PHREEQC speciation calculation program was used to predict possible product phases in the system.

Bond valence calculation results demonstrate discrepancy in the expected bond valence sum values of P, Pb(2), and O(4) atoms in the PbHAp structure. The O(3) atoms were adjusted to improve bond valence sums of P and Pb(2) atoms, but the bond valence sum of Pb(2) was still below its expected oxidation state value. The O(4) atom was moved from (0, 0, 0) to (0, 0, 0.1200) to improve the bond valence sum of the O(4) and Pb(2) atoms. Results after modification of O(3) and O(4) improved the bond valence sums over the published structure but they are still not optimal. These results suggest there is probable error in the published PbHAp structure model.

Results from a gel crystallization method show crystalline products formed inside both pure and  $\text{PO}_4^{3-}$  gel layers after two weeks reaction time. Crystalline product formed in the pure gel layer shows equant crystal morphology while product

formed in the  $\text{PO}_4^{3-}$  gel layer shows plate-like crystal morphology. Products in the pure gel show needle-like crystals on the surface of larger crystalline product indicating multiple product phases in this system consistent with XRD and PHREEQC results. XRD patterns of products obtained in the pure gel layer exhibit mixed phases containing PbHAp,  $\text{PbHPO}_4$ , and  $\text{Pb}_3(\text{PO}_4)_2$  while products formed in the  $\text{PO}_4^{3-}$  gel layer show only peaks due to  $\text{PbHPO}_4$  and  $\text{Pb}_3(\text{PO}_4)_2$  phases. These results are in agreement with PHREEQC results which indicate, PbHAp,  $\text{Pb}_3(\text{PO}_4)_2$ , and  $\text{PbHPO}_4$  are supersaturated. IR spectra of products from both pure and  $\text{PO}_4^{3-}$  gel layers exhibit the  $\nu_1$  and  $\nu_2$  vibrations indicating the  $\text{PO}_4^{3-}$  group in the structure has lower than  $T_d$  symmetry. The decrease in pH from 8 (theoretical for all layers mixed) to 3 for all reactions studied is due to the speciation equilibrium converting  $\text{HPO}_4^{2-}$  to  $\text{H}^+$  and  $\text{PO}_4^{3-}$  as  $\text{PO}_4^{3-}$  containing species are precipitated. The presence of PbHAp in the pure gel layer but not in the  $\text{PO}_4^{3-}$  layer can be understood based on the higher  $\text{Pb}^{2+}:\text{PO}_4^{3-}$  ratio (5:3 vs 3:2) required for the PbHAp phase relative to the  $\text{Pb}_3(\text{PO}_4)_2$  phase and the increment of  $\text{PO}_4^{3-}$  ion concentrations near the lead solution from placing pure gel solution on the  $\text{PO}_4^{3-}$  gel layer in the gel preparation step.

Results from a reflux method show needle-like and hexagonal-rod crystal morphologies of products after refluxing for 24 h and 48 h, respectively. The crystal size increased with increasing reaction time. The EDX spectra of CaHAp substrate and crystalline product show Ca/P or Pb/P ratio of about 5:3 as expected for the respective apatite materials. Low intensity Ca peaks are also observed in the product spectra, consistent with CaHAp impurity due to the growth substrate. This result is consistent with the XRD result that shows mixed phases of CaHAp and PbHAp. The intensity of the PbHAp peaks of the product increased greatly with time and clearly

show PbHAp as the major product phase. IR spectra of CaHAp and products show vibrational bands of  $\text{PO}_4^{3-}$ ,  $\text{H}_2\text{O}$ , and  $\text{NO}_3^-$ .

Vibrational bands of nitrate were observed in products from both gel crystallization and reflux methods. Nitrate may come from the incorporation of residual nitrate from starting compound. However, the nitrate ion does not appear to carry over into the PbHAp product crystals.

Ca-PbHAp materials were also studied in this work. A precipitation method was utilized for preparation of apatite materials. XRD results suggest the CaHAp and PbHAp phases are formed but Ca-PbHAp solid solution is not formed in this system. PHREEQC calculation results show several calcium-phosphate and lead-phosphate phases are supersaturated suggesting multiple products may be formed in this system. However, these phases do not appear clearly in the XRD pattern because they are minor products.

Studies of the formation of apatite and related materials may be an important key for understanding of the precipitation of biological hard tissues and the environmental geology of lead and phosphorus.

**APPENDICES**

# APPENDIX A

## SUPPORTING INFORMATION FOR CHAPTER I

### A.1 $K_{sp}$ with the double formula of CaHAp

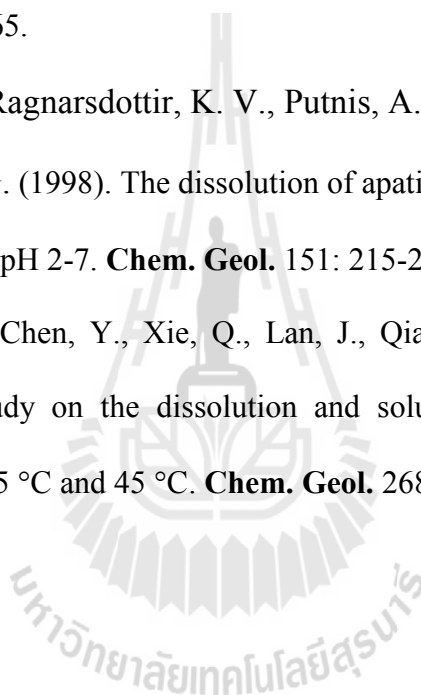

A discrepancy in the  $K_{sp}$  values of CaHAp has been reported (McDowell, Gregory, and Brown, 1997; Valsami-Jones, Ragnarsdottir, Putnis, Bosbach, Kemp, and Cressey, 1998; Tanaka, Miyajima, Nakagaki, and Shimabayashi, 1991; Zhu *et al.*, 2009). The  $K_{sp}$  value of CaHAp calculated from its double formula is 58 orders of magnitude ( $10^{-58}$ ) lower than that calculated from its empirical formula as shown, based on literature reports, in Table A.1. Throughout this thesis the conventional empirical formula has been used for CaHAp and all other ionic compounds.

**Table A.2** The  $K_{sp}$  values of CaHAp materials.

Formula	$K_{sp}$	Author and year
$\text{Ca}_5(\text{PO}_4)_3(\text{OH})$	$10^{-58.3}$	McDowell <i>et al.</i> , 1977
	$10^{-57} - 10^{-59}$	Valsami-Jones <i>et al.</i> , 1998
	$10^{-53.02} - 10^{-53.51}$	Zhu <i>et al.</i> , 2009
$\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$	$10^{-115.8}$	Tanaka <i>et al.</i> , 1991

- **Oratai Saisa-ard** and Kenneth J. Haller. Phase Characterization and Saturation Modeling of the Calcium-lead Phosphate Apatite System, *the 14<sup>th</sup> International ANnual Symposium on Computational Science and Engineering (ANSCSE14)*. 23-26 March 2010. Chiang Rai, Thailand.

- **Oratai Saisa-ard** and Kenneth J. Haller. Gel Crystallization and Physical Characterization of Lead Hydroxyapatite, *International Conference on Materials for Advanced Technologies (ICMAT2011)*, 26 June-1 July 2011. Suntec, Singapore.

##### *Poster presentations*

- **Oratai Saisa-ard**, Winya Dungkaew, Weenawan Somphon, and Kenneth J. Haller. Divalent Cation Incorporation into Calcium Phosphate Hydroxyapatite, *the 8<sup>th</sup> conference of the Asian Crystallographic Association (AsCA'07)*. 4-7 November 2007. Taipei, Taiwan.

- **Oratai Saisa-ard** and Kenneth J. Haller. Study of Synthetic Calcium Phosphate Hydroxyapatite Modified with Pyrophosphate, *the CHE-Congress 2008*. 5-7 September 2008. Chon Buri, Thailand.
- **Oratai Saisa-ard**, Winya Dungkaew, Weenawan Somphon, and Kenneth J. Haller. Structural Study of Lead Incorporation into Calcium Phosphate Hydroxyapatite, *the 33<sup>rd</sup> Congress on Science and Technology of Thailand (STT'33)*. 18-20 October 2007. Nakhon Si Thammarat, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Interaction of Pyrophosphate with Synthetic Calcium Phosphate Hydroxyapatite: Formation of a Surface Complex, *the 34<sup>th</sup> Congress on Science and Technology of Thailand (STT'34)*. 31 October-2 November 2008. Bangkok, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Lead Incorporation into Hydroxyapatite Structure, *German-Thai Symposium on Nanoscience and Nanotechnology (GTSNN'09)*. 21-22 September 2009. Chiang Mai, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Lead Incorporation into Hydroxyapatite Structure, *Pure and Applied Chemistry International Conference (PACCON2010)*. 21-23 January 2010. Ubon Ratchathani, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Gel Crystallization of Calcium-Lead Hydroxyapatite, MHAP (M = Ca<sup>2+</sup> and/or Pb<sup>2+</sup>), *the 10<sup>th</sup> conference of the Asian Crystallographic Association 2010 (AsCA'10)*, 31 October-3 November 2010. Busan, Korea.

- **Oratai Saisa-ard** and Kenneth J. Haller. Structure of Calcium-Lead Hydroxyapatite, MHAP (M = Ca<sup>2+</sup> and/or Pb<sup>2+</sup>), *NanoThailand 2010*. 18-20 November 2010. Pathum Thani, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Synthesis and Characterization of Nitrate Containing Lead Hydroxyapatite, *the 3<sup>rd</sup> Suranaree University of Technology Graduate Conference (SUT-GRAD 3)*. 21-23 November 2010. Nakhon Ratchasima, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Transformation of Synthetic Calcium Phosphate Materials in Lead Solution, *Chiang Mai International Conference on Biomaterials and Applications (CMICBA2011)*, 9-10 August 2011. Chiang Mai, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Single Crystal Growth and Characterization of Lead Hydroxyapatite, *International Union of Crystallography (IUCr2011)*, 22-23 August 2011. Madrid, Spain.
- **Oratai Saisa-ard** and Kenneth J. Haller. Crystallization and Characterization of Lead Phosphate Materials, *Pure and Applied Chemistry International Conference (PACCON2012)*, 11-13 January 2012. Chiang Mai, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Crystallization of Lead Hydroxyapatite from Calcium Hydroxyapatite Dissolution, *the Microscopy Society of Thailand (MST29)*. 31 January-1 February 2012. Phetchaburi, Thailand.

- **Oratai Saisa-ard** and Kenneth J. Haller. Study of Calcium-lead Phosphate Apatite System, *the 4<sup>th</sup> HOPE Meeting*. 7-11 March 2012. Ibaraki, Japan.

## **E.2 Conference proceedings**

### ***Conference proceedings***

- **Oratai Saisa-ard**, Navarat Sodesiri, and Kenneth J. Haller. Cocrystallization and Characterization of an Ethylenediamine and Cyanuric Acid, *the 1<sup>st</sup> Suranaree University of Technology Graduate Conference (SUT-GRAD 1)*. 1-2 November 2007. Nakhon Ratchasima, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Structural Analysis of Calcium and Lead Hydroxyapatite, *the 35<sup>th</sup> Congress on Science and Technology of Thailand (STT'35)*. 15-17 October 2009. Chon Buri, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Crystallization of Lead Phosphate in Gel Systems, *German-Thai Symposium on Nanoscience and Nanotechnology (GTSNN2011)*. 13-16 September 2011. Nakhon Ratchasima, Thailand.
- **Sunaree Choknud**, Oratai Saisa-ard, and Kenneth J. Haller. Preparation and Characterization of Carboxylic Acid Adducts of Gabapentin, *German-Thai Symposium on Nanoscience and Nanotechnology (GTSNN2011)*, 13-16 September 2011. Nakhon Ratchasima, Thailand.
- **Oratai Saisa-ard** and Kenneth J. Haller. Crystallization of Lead Hydroxyapatite from Calcium Hydroxyapatite Dissolution, *the Microscopy Society of Thailand (MST29)*, 31 January-1 February 2012. Phetchaburi, Thailand (submitted).

# CURRICULUM VITAE

## Personal Information:

Name: Oratai Saisa-ard  
Date of Birth: March 6, 1983  
Place of Birth: 84 Moo 1, Tumbon Sangthonoi, Hua Taphan, Amnat Charoen,  
37240, Thailand

## Education:

2005 B.Sc. in Chemistry, Ubon Ratchathani University, Thailand  
2011 Ph.D. in Chemistry, Suranaree University of Technology,  
Thailand

## Scholarship:

2007-2010 The Commission on Higher Education (CHE), Thailand

## Publications:

1. Oratai Saisa-ard and Kenneth J. Haller. Crystallization of Lead Phosphate in Gel Systems, Engineering Journal (accepted for publication).
2. Sunaree Choknud, Oratai Saisa-ard, and Kenneth J. Haller. Preparation and Characterization of Carboxylic Acid Adducts of Gabapentin, Engineering Journal (accepted for publication).
3. Oratai Saisa-ard and Kenneth J. Haller. Crystallization of Lead Hydroxyapatite from Calcium Hydroxyapatite Dissolution, Journal of the Microscopy Society of Thailand (manuscript submitted for publication).
