กันตพัฒน์ ตรินันท์: คำปรากฎร่วมในคลังข้อมูลตัวอย่างภาษาในงานวิจัยตีพิมพ์ด้าน พยาบาลศาสตร์และผลกระทบของการสอนแบบอิงคลังข้อมูลภาษาที่มีต่อการเรียนรู้คำ ปรากฎร่วมของนักศึกษาพยาบาลในมหาวิทยาลัยไทย (LEXICAL COLLOCATIONS IN A SAMPLE CORPUS OF NURSING RESEARCH ARTICLES – SCNRA – AND THE EFFECTS OF CORPUS-BASED INSTRUCTION ON STUDENTS' COLLOCATION LEARNING AT A THAI UNIVERSITY)

อาจารย์ที่ปรึกษา : คร.บุษกร ยอคคำลือ, 334 หน้า

งานวิจัยนี้มีวัตถุประสงค์ 4 ประการ คือ (1) เพื่อระบุและจำแนกคำศัพท์ (Keywords) ที่พบ ในคลังข้อมูลตัวอย่างภาษาในงานวิจัยตีพิมพ์ด้านพยาบาลศาสตร์ (SCNRA) ซึ่งได้รับการตีพิมพ์ใน วารสารวิชาการด้านการพยาบาล (2) เพื่อค้นหาคำปรากฏร่วมในคลังข้อมูลตัวอย่างภาษาในงานวิจัย ตีพิมพ์ด้านพยาบาลสาสตร์ (SCNRA) โดยใช้คำศัพท์ที่พบเป็นคำหลัก (Nodes) เพื่อหาคำปรากฏ ร่วมของคำศัพท์เหล่านั้น และจำแนกคำปรากฏร่วมที่ได้ตามชนิดของการปรากฏร่วมที่เกิดขึ้นตาม ประเภทของคำที่ปรากฏร่วมกัน (3) เพื่อประเมินความรู้ด้านคำปรากฏร่วมที่พบกับนักศึกษา พยาบาลศาสตร์ ชั้นปีที่ 4 ของมหาวิทยาลัยเทคโนโลยีสุรนารี โดยนำคำปรากฏร่วมที่พบจาก การศึกษาข้างต้นมาทำแบบทดสอบ และ (4) เพื่อนำคำปรากฏร่วมที่ได้จากการศึกษาไปถ่ายทอดให้ ความรู้แก่นักศึกษาพยาบาลศาสตร์และประเมินผลของการสอนแบบอิงคลังข้อมูลภาษา (Corpusbased Instruction) ที่มีต่อคะแนนของนักศึกษาเปรียบเทียบระหว่างก่อนและหลังการสอน

งานวิจัยส่วนแรก เริ่มด้วยการรวบรวมบทความงานวิจัยที่ตีพิมพ์ในวารสารวิชาการด้านการ พยาบาล จำนวน 300 เรื่อง จากวารสารวิชาการจำนวน 10 วารสาร ที่เข้าถึงได้ผ่านบริการของศูนย์ บรรณสาร มหาวิทยาลัยเทคโนโลยีสุรนารี โดยบทความที่รวบรวมแต่ละเรื่องถูกบันทึกเป็นไฟล์ นามสกุล .txt เมื่อรวบรวมได้ครบจำนวนแล้ว ไฟล์เหล่านี้ถูกโหลดเข้าไปในโปรแกรมจัดการ คลังข้อมูลภาษาชื่อ AntConc เพื่อสร้างคลังข้อมูลตัวอย่างภาษาในงานวิจัยตีพิมพ์ด้านพยาบาล ศาสตร์ (SCNRA) ซึ่งประกอบด้วยจำนวนคำกว่า 1.25 ล้านคำ จากการประมวลผลภายใต้เกณฑ์ที่ กำหนด คลังข้อมูลตัวอย่างภาษาที่สร้างขึ้นนี้มีคำศัพท์ (Keywords) จำนวน 717 คำ ซึ่งคำศัพท์ เหล่านี้ถูกนำไปใช้เป็น คำหลัก (Nodes) เพื่อหาคำปรากฏร่วม ผลลัพธ์คือ มีคำปรากฏร่วมจำนวน 2,14 8 คู่ แบ่งออกเป็น 14 ประเภทของคำที่ปรากฏร่วมกัน โดยคำปรากฏร่วม ทุ่นศัพท์+นาม (N=610; 28.4%) ลำดับที่สามคือ คำปรากฏร่วม นาม+นาม (N=889; 41.39%) ลำดับที่สองคือคำปรากฏร่วม คุณศัพท์+นาม (N=610; 28.4%) ลำดับที่สามคือ คำปรากฏร่วม นาม+กริยา (N=240; 11.17%) ในส่วนของคำศัพท์ ส่วน

ใหญ่เป็นคำนาม (N = 463; 63.51%) ตามมาด้วยคำคุณศัพท์ (N = 157; 21.54%) อำดับที่สามคือ คำกริยา (N = 98; 13.44%) และคำวิเศษณ์มีจำนวนน้อยที่สุด (N = 11; 1.51%)

งานวิจัยส่วนที่สอง ว่าด้วยความรู้เกี่ยวกับคำปรากฏร่วมค้านการพยาบาลของนักศึกษา พยาบาสสาสคร์ ซึ่งเริ่มด้วยการสร้างแบบทดสอบข้ำนวน 60 ข้อ ประกอบค้วย แบบตัวเลือก จำนวน 30 ข้อ แบบเดิมคำในช่องว่าง จำนวน 20 ข้อ และแบบเขียนประโยก 10 ข้อ และใช้ทดสอบกับ นักศึกษาพยาบาลศาสตร์ ชั้นปีที่ 4 จำนวน 51 คน โดยมีการทดสอบก่อนเรียน การอบรมให้ความรู้ เกี่ยวกับคำปรากฏร่วมที่พบจากการวิจัย และการทดสอบหลังเรียน ผลการทดสอบก่อนเรียนพบว่า ค่าเลลี่ยละแนนรวม = 30.66 โดยมีส่วนเบี่ยงเบนมาตรฐาน = 7.41 (\overline{x} = 30.66; SD = 7.41) ซึ่งบ่งชี้ว่า โดยรวมแล้วนักศึกษามีความรู้เกี่ยวกับคำปรากฏร่วมอยู่ในระดับ "ผลการทดสอบหลังเรียน พบว่า ค่าเลลี่ยละแนนรวม = 39.44 มีส่วนเบี่ยงเบนมาตรฐาน = 7.65 (\overline{x} = 39.44; SD = 7.65) ซึ่งบ่งชี้ ว่าโดยรวมแล้วนักศึกษามีความรู้เกี่ยวกับคำปรากฏร่วมอยู่ในระดับ "ดี" ผลกะแนนระหว่างการ ทดสอบก่อนเรียนและหลังเรียนเปรียนเทียบโดยใช้ paired samples (-test แสดงให้เห็นว่านักศึกษา ทำละแนนได้ดีขึ้นอย่างมีนัยสำคัญ ที่ระดับน้อยกว่า 0.001 ทั้งคะแนนโดยรวมและแต่ส่วนของ แบบทดสอบ ในส่วนของความสามารถของนักศึกษา พบว่านักศึกษาส่วนใหญ่ทำละแนนได้ดีขึ้น หนึ่งระดับ จากระดับ จากระดับ "พอใช้" เป็นระดับ "ดี" ยกเว้นเว้นในส่วนที่สาม การเขียนประโยค ที่พบว่า นักศึกษาส่วนใหญ่ทำละแนนได้ดีขึ้นหนึ่งระดับ จำกระดับ "อ่อน" เป็นระดับ "พอใช้"

KANTAPAT TRINANT: LEXICAL COLLOCATIONS IN A SAMPLE CORPUS OF NURSING RESEARCH ARTICLES (SCNRA) AND THE EFFECTS OF CORPUS-BASED INSTRUCTION ON STUDENTS, COLLOCATION LEARNING AT A THAI UNIVERSITY. THESIS ADVISOR: BUTSAKORN YODKAMLUE, Ph.D., 334 PP.

CORPUS-BASED STUDY/ CORPUS-BASED INSTRUCTION/ NURSING COLLOCATIONS/ COLLOCATION TEST/ COLLOCATION KNOWLEDGE

The present study was conducted to (1) identify and classify keywords in the Sample Corpus of Nursing Research Articles (SCNRA); (2) explore lexical collocations found in the SCNRA using keywords extracted as 'nodes' to find their 'collocates', and to classify the collocation pairs according to their combination types; (3) assess collocation knowledge of nursing students at Suranaree University of Technology (SUT) based on the test constructed from collocations extracted from the SCNRA; and (4) provide lessons applying corpus-based instruction on nursing collocations and assess the effects on the students' performance.

The research started with the compilation of 300 research articles from 10 selected academic journals in the field of nursing accessible online via SUT's Library Resources by saving into text files then uploaded onto a corpus tool, the AntConc, to form the SCNRA which comprised over 1.25 million running words. 717 keywords were obtained under the set criteria which then were used as the "nodes" to find their collocates. 2,148 pairs of lexical collocations were obtained with 14 combination types. The majority of them were Noun + Noun (N = 889; 41.39%) followed by

Adjective + Noun (N = 610; 28.4%), and Noun + Verb (N = 240; 11.17%). In terms of the keywords, the majority of them were Nouns (N = 463; 63.51%) followed by Adjectives (N = 157; 21.54%), and Verbs (N = 98; 13.44%) with Adverbs came last (N = 11; 1.51%).

In terms of collocational knowledge of nursing students, Nursing Collocation Test was constructed containing three parts: 30 multiple-choice items; 20 gap-filling items; and 10 items of a sentence writing task. The Test was then administered with 51 fourth year nursing students at SUT before and after a corpus-based instruction on nursing collocations organized for them. The pre-test's mean of the total score revealed that the overall knowledge of collocations of the majority of the students was at a "Fair" level ($\bar{x} = 30.66$; SD = 7.41). The post-test's mean of the total score showed that the overall performance of the majority of them had improved to a "Good" level $(\bar{x}=39.44; SD=7.65)$. To evaluate the effects of corpus-based instruction on the students' performance, the results of the pre-test and the post-test were compared using paired samples t-test. The results showed that there was a statistically significant improvement of the students' performance in the total score $(t(50)) = (-1)^{-1}$ 11.75), p = <0.001) as well as in each of the three parts of the test: part 1 (t(50) = (-1.75)). 7.47), p = <0.001); part 2 (t(50) = (-8.10), p = <0.001); and part 3 (t(50) = (-7.44), p = <0.001) <0.001). In terms of the students' performance, the majority of the students' scores increased and put them one level higher in all parts from "Fair" to "Good", except for part 3, a sentence writing task, the level of performance was improved from "Poor" to "Fair".

ACKNOWLEDGEMENTS

This research project would not have been accomplished without the help from several involved parties. Firstly, I would like to express my gratitude to my advisor, Dr. Butsakorn Yodkamlue, who has guided me from the start to the end. Her patience, kindness and devotion as well as her insightful comments and suggestions have been provided along the path of the project.

Secondly, I would like to express my thankfulness to all the committee members: Asst. Prof. Dr. Issra Pramoolsuk, Asst. Prof. Dr. Kornwipa Poonpon, Dr. Sirinthon Sripho, and Dr. Adcharawan Buripakdi, for their expert comments and suggestions on my work.

Thirdly, I am indebted to the kind cooperation granted by the Institute of Nursing, Suranaree University of Technology. Without the participation from the fourth year nursing students in the academic year 2016 and 2017 for the tryout test and the workshop with the pre-test and the post-test, this research project would not have been accomplished.

Fourthly, I am grateful for all the faculty and staff at School of Foreign Languages, Institute of Social Technology, Suranaree University of Technology for their kind support and assistance. I am also thankful for the financial support in the form of tuition fee granted for my first three years by Suranaree University of Technology.

Fifthly, I would like to thank the Faculty of Liberal Arts and Ubon Ratchathani University for granting me full time study leave permission with full pay. I would also like to thank all my colleagues at the Department of Western Languages and Literature and the Faculty of Liberal Arts for their moral support.

Last but not least, I am thankful for all my teachers who taught me in primary school, middle school, high school, and universities. Without them, I would not be the person who I am today. My family and friends, near and far, you know that you have always been a powerful force for me to keep moving forward. I really appreciate you all.

Kantapat Trinant

CHAPTER 1

INTRODUCTION

This chapter presents background of the present study which leads to the rationale, purposes of the study and the research questions. The significance of the study is also provided afterwards, followed by the scope and limitations of the present study. Then the definitions of key terms are given. The chapter ends with the summary of the chapter.

1.1 Background

Today's era of globalization has led to the need for greater integration among groups of countries. The European Union (EU) is the first of this kind. The ASEAN is currently attempting to follow suit by announcing the economic integration – The ASEAN Economic Community (AEC) – by the end of the year 2015. The 10 member countries have agreed on several matters in order to facilitate the economic integration among them. One important agreement is the mobilization of professional services. This would be proceeded under the Mutual Recognition Arrangements (MRAs). Under the MRAs, there will be the free flow of professional-level labor within the member countries in seven fields, which are engineering, architectural, surveying, medical, dental, nursing, and accounting services (Aldaba, 2013).

Although there seems to be more opportunities for skilled labor to work outside of their countries, what seems to prevent them from doing so, besides other

matters, is the language barrier. Professional knowledge alone will not be sufficient for professionals who seek to pursue their career outside of their motherland where the language used is not their mother tongue. This is particularly a concern for Thai professionals since English skills seem to be the major constraint for them. As clearly stated in article 34 of the ASEAN Charter (2008) that English is the working language of the ASEAN community, it is crucial for these professionals to be fluent in English in order to gain better opportunities in their careers abroad.

In the teaching and learning of English as a foreign language (EFL) or English as a second language (ESL), vocabulary and grammar have always been regarded as essential elements. Nation and Waring (1997) suggest that EFL/ESL learners need to know about 3,000 high frequency words in order to use the language to communicate successfully. Similarly, Sökmen (1997) states that knowing the 2,000 most frequent words in English can be very helpful for the learners. This belief is reflected in several methods of teaching, namely, grammar translation, direct method, and audio lingual. Even in the more recently introduced methods such as communicative language teaching (CLT), though grammar rules may not be strictly in focus, a large repertoire of vocabulary is still emphasized (Richards, 2006). This incident is supported by Nation (2011) as he claims that although the CLT approach "initially had a largely negative effect on the deliberate teaching and learning of vocabulary, teachers have continued to see the importance of giving direct attention to words" (p. 535). Milton (2013) also asserts that vocabulary knowledge is an effective indicator of the four skills of the language.

However, simply knowing a lot of vocabulary and the grammar rules does not seem to be enough to guarantee the correct and appropriate use of the language

(Lewis, 2000). This is because natural language is produced from the 'prefabricated chunks' or fixed terms that the language users have stored in their mental lexicons. Lewis (2002a) also further points out that many learners who know quite a lot of nouns fail to use them effectively. The reason for this is the lack of the awareness on the other words which co-occur with those nouns. Wray (2002) and Hoey (2007) also assert that native speakers of a language subconsciously keep a record of the context and co-context of the words they have encountered, so that they can use later at the right time and right occasions. This causes more trouble for non-native speakers in producing the language to be as naturally as their counterpart native speakers.

Collocation, which is a kind of prefabricated chunks, plays an important role in the production of natural language (Hoey, 2007). Thus, to be fluent in English, EFL/ESL learners should be aware of collocations and how to use them, especially for collocations in their professional field. Communicative competence is resulted directly from the mastery of prefabricated chunks or formulaic sequences (FSs) which collocation is one aspect of them (Henriksen, 2013). In order to master these aspects of the language, the ability to memorize and chunk them into units plays a crucial role. Consequently, there have been research and studies on both FSs and collocations in particular such as Lewis (2000), Schmitt (2004), and Wood (2010).

The term 'collocation', which is derived from the Latin word 'collocare' means to place together or to assemble, was first introduced by the British contextualist, John R. Firth. He gives the meaning of the term as "collocations of a given word are statements of the habitual and customary places of that word" (1957, p. 181). According to Henriksen (2013), collocations are frequently recurring two-to-three word syntagmatic units. They can be both lexical and grammatical collocations.

Lexical collocations are such as the co-occurring of noun + noun (*air conditioner*), verb + noun (*pay tribute*), and adjective + noun (*hot spice*). Grammatical collocations are such as preposition + noun (*on guard*) and adjective + preposition (*immune to*).

According to Hill (2000), collocation is believed to be an important key to fluency. Collocation, at the same time, has been a huge barrier for EFL/ESL learners to achieve a native-like fluency. A number of studies on collocations have revealed that even high-level learners seem to face problems in using and developing second language (L2) collocational knowledge (Arnaud & Savignon, 1997; Farrokh, 2012; Nesselhauf, 2005). According to the hierarchy of mistakes created by McCretton and Rider¹, collocations are found to be the most frequent mistakes made by L2 learners (James, 1998; Miščin, 2013). Examples of collocational errors given by James (1998) are: 1) semantic error, e.g., 'crooked stick' is replaced by 'crooked year'; and 2) statistical weighed preference error, e.g., 'big losses' is used instead of 'heavy losses' (p. 152). According to Martin (1984), collocational mismatches are common in the language produced by L2 learners. This is because they hardly encounter a word or combination of words to enable them to determine its range or narrow the item down to its more fixed partnerships resulted from the inadequate exposure to the language. This difficulty particularly occurs with those semantic opaque combinations, when the combination of words leads to the change of the original meaning, or with specific field of the discourse such as engineering or nursing.

The Most Serious

Lexis =>spelling =>negation =>word order =>prepositions => verb forms => concord

Although collocation has become a topic of study by scholars since the late 1950s, the study of collocations generally has not been extensively conducted. Most studies have been conducted on collocations in general English (Gledhill, 1996; Granger & Bestgen, 2014; Namvar, Mohd Nor, Ibrahim, & Mustafa, 2012; Wang & Good, 2007; and Webb, Newton, & Chang 2013). For collocations in scientific and professional fields, Mudraya (2006) and Ward (2009) have conducted the studies by looking at engineering textbooks. Menon and Mukundan (2012) explored collocations of high frequency noun keywords in prescribed science textbooks. Takač and Miščin (2013) looked at the collocational competence of non-native users of medical English. Miščin (2013) also investigated verb collocations in medical English.

From the above mentioned studies, it is evident that the study of collocations found in field of nursing, particularly in nursing research articles, is still rare. A nursing academic word list recently created by Yang (2015) is a study devoted to the field of nursing in terms of lexical approach. Since nursing is one of the professions that have been increasingly internationalized along with other health related professions, it is important for nursing students as well as nursing professionals to foster their competence in the use of English language before entering into their professional arena. One step to prepare them for reaching such goal, apart from other skills in English and beyond the knowledge of grammar and vocabulary, is the knowledge of collocations.

As the urge for regional integration is becoming reality with the free flow of skilled workers, preparing eligible professionals for the phenomenon is a wise response to act. For nursing professionals, facilitating them with collocations in their field could bring a great deal of benefits to the concerned parties. With collocations in

their professional field identified, it is believed that they would be able to communicate more effectively with their international colleagues as well as to progress in their career further by conducting research or further their study.

In addition, as it is difficult to judge how much knowledge of collocations nursing professionals have, a test of collocation knowledge has a role to play. Vasiljevic (2014) points out that in order to assess learners' needs and their lexical progress, a test of collocation knowledge is necessary. A test in itself not only measures the knowledge of the collocations learners have, but also can have a positive effect on them by increasing their awareness of collocations. Moreover, lessons on collocations extracted from the study would be designed and provided to the fourth year nursing students at Suranaree University of Technology (SUT). The effect of corpus-based instruction of collocations would then be assessed with the pre-test and the post-test.

Since knowledge of collocations is perceived as essential for effective and natural communication, it is necessary for professionals of all fields to have adequate knowledge of collocations in their fields. The application of corpus-based studies is a useful tool in identifying and studying collocations. A test of collocation knowledge is also a useful tool in assessing knowledge of collocations a person has. Therefore, the present study intended to apply both corpus-based study of collocations and a test of collocation knowledge to explore lexical collocations in a sample corpus of nursing research articles and the knowledge of collocation of the fourth year nursing students at SUT.

Nursing curriculum and nursing students at SUT

From the interview with an informant from the Institute of Nursing who was a senior academic staff, at the academic year 2016, there were 45 fourth year and 65 third year nursing students. In terms of English Courses required for the program, there were five English compulsory courses, which are English I to English V, taught by instructors from the School of Foreign Languages. The focus of these courses is to enable students to use English for communication in all four main skills. The courses also enable the teaching to assigned tasks that suit students' specific field of study.

There was one elective English course taught by the faculty members of the Institute of Nursing. The course was English for Nursing Profession. This elective English course has been designed to prepare nursing students for their nursing profession. The instructors were from the faculty members as they were familiar with the subject matters and working environment of nurses. Furthermore, for each nursing course, particularly in each specialized area of nursing, as textbooks used were usually in English, the first three hours of class was taught using English as a medium. This content-based instruction is believed to encourage students to use English and familiar with using English in their profession. The specialized areas currently being offered at the Institute of Nursing are: (1) Nursing care of families and midwifery, (2) Nursing care of the child and adolescent, (3) Adult and elderly nursing, (4) Community nursing, (5) Psychiatric nursing, and (6) Fundamental nursing.

In terms of academic and research articles, from the third year onwards, nursing students at the Institute of Nursing are required to read academic and research articles relevant to the courses of the specialized areas taken. This aims to encourage students to get familiar with reading academic and research articles in their field to

apply the knowledge gained in their professional practice. The students also knew how to access academic and research articles as they had to take a course in the program called 'Nursing Informatics' in their second year. The SUT library also arranged the workshops for new students on how to access resources available both on traditional paper-based texts and online materials.

Despite the fact that the nursing curriculum at SUT seems to provide necessary courses both in their specialized field and English courses, it is uncertain in terms of collocations used in nursing research articles either being recognized by the students or their knowledge of those collocations. Therefore, the present study intended to investigate into this issue and hope to gain useful information and helpful means in response to it.

1.2 Rationale of the study

It has been suggested by Schmitt (2010) and Milton (2013) that knowing the vocabulary is a crucial component for EFL/ESL learners to achieve certain level of fluency in the language being learned. Having enough of the vocabulary repertoire, learners can predict their other language skills namely reading, writing, speaking, and listening. Thus, to be able to understand the language and produce the language for effective communication, learners need to acquire enough vocabulary. This traditional view is reflected in Lewis' statement that "...grammar is creative, while words are like building bricks, fixed packages of meaning" (2002a, p. 37). This statement of Lewis shows how important vocabulary is in knowing a language. Without enough vocabulary, learners will face difficulty in constructing sentences. This is similar to not having enough bricks which could prevent a building from being built.

Though vocabulary is seen as an essential element in knowing a language, vocabulary alone or even with the grammatical rules is not enough to enable learners to produce natural language or native-like expressions (Nation, 2001). Rather, collocation, which is closely related to vocabulary in the form of formulaic language or chunks, plays an important role in effective and natural communication. Vocabulary knowledge, according to Shokouhi and Mirsalari (2010) and Gaballa and Al-Khayri (2014), involves knowing more than just the meanings or basic meanings of words in isolation, but also the words that tend to co-occur with them. According to Nation (2001), collocations play a very important role in knowing a language with three aspects. Firstly, language knowledge is collocational knowledge. This is because the stored sequences of words are the bases of learning, knowledge and use. Secondly, all fluent and appropriate language use requires collocational knowledge. To produce a native-like language, collocations play the essential role in it. Finally, many words are used in a limited set of collocations and knowing these is a part of what is involved in knowing the words.

Howarth (1998 as cited in Henriksen, 2013) claims that the use of formulaic language as the terms 'formulaic sequences' (FSs), which include collocations, is very genre-specific. Mastery of collocations may be reflected on clarity, precision and lack of ambiguity in language production. As collocations act as central composite syntactic units for clause level production, lack of collocational knowledge may be expected to have a negative effect on L2 performance both productively and receptively. This could lead to the misunderstanding of the message. Lack of collocational competence may also indicate an inadequate academic expertise.

Millar's (2011) study also found that incorrect use of collocations can reduce processing speed even for native speakers.

In professional practice, effective and appropriate use of language is indispensible. As it takes time to master a second language such as English, university students of all professional fields are required to take English courses as part of their curricula. This is also the case in Thai universities. Apart from general English courses, there are also English for Academic Purposes (EAP) and English for Specific Purposes (ESP) courses. In the field of nursing, there is no exception. For nurses, their effective and natural use of English among themselves, with doctors, and with patients is very important. Thus, identifying and classifying collocations found in research articles in the field should make it useful for lexical learning and teaching in the area of nursing collocations. This should also be easier for teachers and students to be explicitly aware of collocations in their field which will certainly benefit them for producing the language in all four skills more effectively and naturally. This can be particularly important for nursing students and professional nurses as they need to read a number of research articles in their specialized areas to apply in their real practice. Additionally, lessons designed based on the collocations gained from the study to teach the fourth year nursing students at SUT should be a great deal of benefit. A pre-test and a post-test administered to compare the results should also reveal the knowledge of the students and the implication for teaching.

1.3 Purposes of the Study

It is apparent that it is inevitable for professional nurses to be efficient in English for both their professional advancement and further study. However, there seem to be obstacles preventing them from achieving their goals. These obstacles are mainly the inadequate knowledge and lack of awareness of collocations. Besides, there has not been a study of collocations in the field of nursing, particularly from a corpus of nursing research articles. Thus the present study attempted to fill up these gaps by building a Sample Corpus of Nursing Research Article (SCNRA) from which the keyword list and the collocations can be generated. As well, a collocation test based on the collocations generated from the study was built and administered with the fourth year nursing students at SUT to evaluate their collocational knowledge. The lessons on nursing collocations have been provided with the test afterwards to measure their progress.

The aims of the present study were as follows:

- 1) To identify and classify keywords found in the Sample Corpus of Nursing Research Articles (SCNRA) published in international journals in the field of nursing,
- 2) To explore lexical collocations found in the SCNRA using keywords found as 'nodes' to find their 'collocates', and to classify collocations found according to their combinations,
- 3) To assess collocation knowledge of the fourth year nursing students at SUT based on the collocations found from the SCNRA, and
- 4) To provide lessons on nursing collocations and assess the effect of corpusbased instruction.

1.4 Research Questions

The research questions of the present study are the followings:

- 1) What are the keywords in the SCNRA based on the frequency of occurrence at ≥ 50 and the keyness value at ≥ 20 ? What is the proportion according to their parts of speech?
- 2) What are the lexical collocations of the keywords in the SCNRA? What is the proportion according to each type of combinations?
- 3) How much collocational knowledge do the fourth year nursing students at Suranaree University of Technology (SUT) have based on a test of collocations extracted from the SCNRA?
- 4) How much does corpus-based instruction help improve the knowledge of collocations for the fourth year nursing students at SUT?

1.5 Significance of the Study

As collocational knowledge plays an essential part in effective and natural production of language (Nation, 2001), extracting and classifying keywords and collocations from the SCNRA should be beneficial in a number of aspects.

In terms of EFL/ESL learning and teaching, the present study could contribute to the field as follows:

- 1) With the list of keywords and collocations gathered directly from the SCNRA, it should be more convenient for nursing students as well as nursing professionals to learn and acquire these keywords and lexical collocations.
- 2) The keyword list and collocations generated from the study should be particularly useful for nursing students and professional nurses who are conducting research in the field as the collocations could help improve their reading and writing skills.

- 3) It should be less time consuming for the language instructors who teach English for Specific Purposes (ESP) for nursing students to point out to their students if corpus-based instruction of collocations in their field is beneficial.
- 4) These collocations should also benefit any EFL/ESL learners who are interested in collocations in the field of nursing and learning of English in general.

In terms of corpus-based study, the present study generates a list of specific keywords and collocations, specifically lexical collocations, to the field. This should add new resource and body of knowledge to the field.

A test of collocational knowledge constructed based on lexical collocations identified from the study should also be valuable to the EFL/ESL teaching and learning as follows:

- 1) The test should reveal how much knowledge nursing students have on collocations found in the SCNRA.
- 2) This may have the pedagogical implications whether collocations found in the SCNRA should be taught explicitly or not based on the test results.
- 3) The collocation test created may be a useful tool for assessing the knowledge of collocations in the field of nursing in general.

Lastly, lessons on collocations found in the SCNRA could be directly beneficial to the teaching and learning of collocations in the field.

1.6 Scope and Limitations of the Study

The scope and limitations of the present study were as follows:

1) It aimed to explore keywords and collocations found in selected research articles in the field of nursing.

- 2) The research articles used to compile into a sample corpus were those selected from 10 international nursing journals which were available online and accessible via SUT's library resources. These 10 journals had been selected based on the fields which were offered at Institute of Nursing at SUT. Therefore, not all of the fields were included.
- 3) Thirty research articles selected from each selected journals were based on the latest issues as they should represent the up-to-date collocations in the field accessible, which make up the total of 300 research articles to form the SCNRA.
- 4) As the focus of the present study was on lexical collocations with threeword span on the right side of the nodes, the collocations to be investigated can be those with the word span from two to four words.
- 5) The test of collocations constructed based on lexical collocations produced from the study aimed to be administered with the fourth year undergraduate students of nursing at SUT to determine the level of their collocational knowledge in the field. This group of students was the target for the test as they were among the target users of the journals and in their final year which would soon enter their professional lives or further their study.

1.7 Definitions of Key Terms

Collocation, in this study, refers to the co-occurrence of words which is predictable as they have tendency to occur together and are naturally co-selected by native speakers.

Lexical collocation, in this study, refers the co-occurrence of two content words within two to four word span found in the SCNRA. The co-occurrence tends to

occur naturally with statistical significance in terms of their association. The cooccurring will be examined based on the nodes which are the content word combinations (Verb + noun, Adj. + noun, Noun + verb, Noun + noun, Adv. + adj., and Verb + adv.) adapted from the seven types provided by Benson et al. (2010).

Nursing Journals refers to international journals in the field of nursing accessible via Suranaree University of Technology's (SUT) library resources and research articles are taken from the selected journals for the present study.

Nursing research articles refer to research articles taken from 10 purposively selected journals in the field of nursing accessible via SUT's library resources. These journals closely match with the specialized areas of nursing offered at SUT.

Corpus (plural: corpora) refers to a collection of texts either written or spoken of a particular genre or variety of genres for a particular purpose of analysis. A corpus is stored in an electronic form to be readable by a computer program. In the present study, a corpus refers to a collection of the selected 300 research articles in the field of nursing which is stored in an electronic form known as the SCNRA to be analyzed by a concordance program for lexical collocations.

Sample Corpus of Nursing Research Articles (SCNRA) refers to the sample corpus built for the present study. The SCNRA comprises of 300 research articles from the selected 10 journals of nursing, 30 latest articles from each.

Collocational knowledge refers to knowledge of collocations a person has which often leads to and affects collocational competence and communicative competence.

Test of Collocation Knowledge refers to a set of test constructed based on lexical collocations identified from the SCNRA created for the present study. It is

meant to evaluate the knowledge of the fourth year nursing students on lexical collocations found in the SCNRA. This test will be applied twice with the same target group of students as a pre-test and a post-test.

1.8 Summary of the Chapter

This chapter presented background of the present study which leads to the rationale, purposes of the study and the research questions. The significance of the study has also been provided. The scope and limitations of the present study has been described. The definitions of key terms in the present study were given. The following chapter provides reviews on related literature concerning the present study.

CHAPTER 2

LITERATURE REVIEW

This chapter provides reviews of the literature related to the present study. Before touching on collocations, the chapter begins with exploring the relationship between vocabulary and collocations in second language acquisition (SLA) as well as the learning and teaching vocabulary. The information on lexis and lexical approach, formulaic language, and mental lexicon are included in the first part. The second part of the chapter devotes to collocations which covers the definitions, the classifications, the types, and the criteria for identification. The importance of collocation as well as the teaching and tests of collocation knowledge are also provided. The third part provides information on corpus studies, which includes the definitions, the development, types, and benefits. The information on concordance software, corpusbased lexical analysis as well as corpus-based language teaching and learning are also illustrated. The fourth part gives information on English for Specific Purposes (ESP) in relation to collocations teaching and learning as well as corpus-based instruction. The fifth part introduces pre-experimental research design. The sixth part gives review concerning journals and journal articles as well as nursing journal and journal articles. The last part gives the theoretical framework of the present study.

2.1 Vocabulary and SLA

This part presents the roles vocabulary play in the acquisition of a second language. The views of scholars on how vocabulary and collocation are related and the learning and teaching of vocabulary in connection with SLA are under reviewed. Lexical approach and lexical items, formulaic language, and mental lexicon also are under reviewed as they relate closely to vocabulary as its larger units.

2.1.1 Vocabulary and Collocation

Vocabulary has been categorized into groups by some scholars. Widdowson (1983) classifies words into two groups: schematically bound and words of high indexical or procedural. The schematically bound words can be identified by their use in that they narrow the frames of reference and identify particular fields. They are words that can be used in specific contexts. Indexical or procedural words, on the other hand, can be found in wider range of contexts. They can be used to define and locate within their fields. The example can be seen in the words 'hydrometer' and 'instrument'. The former can be found in a more specific area of texts, while the latter can be found in wider circumstances as well as can be used to define the former. Thus 'hydrometer' is classified as a schematically bound word, while 'instrument' is a high indexical word.

McCarthy (1990) classifies vocabulary into two distinct groups: core vocabulary and procedural vocabulary. Core vocabulary refers to those words with more influential in terms of meanings and uses. The core vocabulary tends to be usable in various contexts with different word-classes. Procedural vocabulary refers to those that are used to talk about other words, to paraphrase, to define, and to organize them in communication. Comparing the words 'fat' and 'obese', for example, are

similar in meaning. However, 'fat' can be found in more places than 'obese' such as 'fat man', 'fat chance', 'fat wallet'. In this case, 'fat' has a quality as a core vocabulary, while 'obese' is a procedural vocabulary.

Carter (1998), meanwhile, categorizes words into two groups: grammatical and lexical words. Grammatical words are those known as 'functional words', functors', or 'empty words'. They do not represent meanings. These grammatical words include pronouns, articles, auxiliary verbs, prepositions, and conjunctions. Lexical words, on the other hand, are those known as 'full words' or 'content words'. They carry meanings or information contents. This group of words includes the nouns, adjectives, verbs, and adverbs. Lexical items are groups of words that go together such as multi-word verbs, phrasal verbs, and idioms. They are sometimes called "vocabulary items" or simply "items". The term is useful and fairly natural hold-all term which captures and helps to overcome instabilities in the term 'word'.

In second language acquisition (SLA), vocabulary repertoire of the target language plays an important part in achieving certain level of fluency. Godwin-Jones (2010) states that "an essential element of language learning is building one's personal store of words and expressions" (p. 4). This will then lead to the competence in all other areas of communication. Tight (2010) also claims that "lexical development is an essential step in second language acquisition" (p. 792). Vocabulary is so important in the acquisition of second language that "no amount of grammatical or other type of linguistic knowledge can be employed in communication or discourse without the mediation of vocabulary" (Richards, 2000, p. xi, as cited in Tight, 2010).

However, Schmitt (2010) points out that the vocabulary is important for language use with the larger is the better. Formulaic language is as well important as

individual words. Schmitt's view is in agreement with a statement made by Nation (2001) that knowing vocabulary involves knowing the other words they typically cooccur with. For example, 'fast food' cannot be replaced by 'speedy food' or 'quick food'. Collocation (Nation, 2001) is the only one relationship that relates to the appropriate interpretation and productive use of vocabulary. Thus, vocabulary and its extension play an important role in the acquisition of a language.

According to Takač (2008), 'lexeme' or 'lexical unit' covers a number of word types namely inflections, polysemy, and multi-word items. This leads to an agreement among SLA linguists and theorists that vocabulary is made up of a variety of forms such as morphemes, compounds, idioms and other fixed expressions. Lexical items can hardly be viewed in isolation since their meaning can be studied through componential analysis emerged from the relationship of the combined words, which is called a syntagmatic relationship. This relationship is characterized by restricted linear sequencing of lexemes. These restrictions determine acceptable lexical units to co-occur as finally known as collocations.

From the above mentioned views on vocabulary and its relation to the acquisition of a second language, it is clear that the unit larger than single words is important. Thus, learning and teaching of vocabulary should extend further to formulaic language in which collocation is included as one of its kind. Therefore, in order to develop learners' communicative competence, 'collocation' is one of the most effective techniques (Yoshida, 2013).

2.1.2 Teaching and Learning of Vocabulary

According to Schmitt (2000), vocabulary is not simply learnt receptively at the beginning and productive knowledge can occur automatically later. This is because

words are complex by nature. Nation (1990 as cited in Schmitt, 2010) has listed eight different aspects of knowledge a person must master in order to know a word as follows: its meaning(s), its written form, its spoken form, its grammatical patterns, its collocations, its register, its associations, and its frequency. The different aspects of word knowledge are not necessarily learnt at the same time. Each aspect of word knowledge is likely to be learnt in a gradual manner. Therefore, the acquisition of vocabulary is 'incremental' since it is impossible to learn all of the aspects at the same time.

Nation (1990) points out that there are two approaches in vocabulary learning: direct and indirect. The former occurs when learners do exercises and activities that intend to help them learn particular words. The latter approach is applied when the attention of the learners is not directly on the vocabulary, but more on a broader context such as understanding the passage of the reading instead of some particular words.

The vocabulary teaching approach suggested by Nation (1990), thus, is to apply the two approaches in four ways from the most indirect to the most direct as follows: 1) Use prepared materials that are simplified to suit learners' level; 2) Give attention to the unknown words by giving appropriate explanation; 3) Teach vocabulary in relation to other language activities or recycle the vocabulary in other activities; and 4) Spend time both in class and outside class on learning vocabulary with activities that are not directly linked to language activities.

Schmitt (2000) also states in regard to the teaching and learning of vocabulary that there needs to be the combinations of both explicit teaching and activities that will allow incidental learning to occur. It is also suggested that there is the

relationship between the learners' level of proficiency and the teaching approaches whether it should be explicit or indirect. In this case, the low level learners need more explicit teaching of vocabulary, while the higher level may need less. Both explicit and incidental approaches are important in vocabulary acquisition.

Explicit approach to vocabulary acquisition

Schmitt (2000) suggests three methods of explicit approach to vocabulary acquisition as follows:

- 1) Integrating new words with old (Sökmen, 1997) is one of the explicit approaches in helping learners to acquire the language. It can be done by grouping similar words together.
- 2) Teaching the underlying meaning concept of a word. This is because many words are polysemous and some of their different meaning senses have a common underlying trait. By defining the underlying meaning concept of the words, learners can understand the words in a wider variety of contexts.
- 3) Teaching word families instead of individual word forms. This can be done by mentioning other members of a word family when introducing a new word. Learners may be asked to guess a new word's derivatives as well as including a derivation section as part of assessment.

Incidental learning approach to vocabulary acquisition

Getting maximum exposure to the target language is the most important element for incidental learning of a second language. The best way to do this is joining students' exchange program to spend time in the target language environment (Milton & Meara, 1995; Schmitt, 2000). However, most L2 learners do not have such opportunity to be exposed to the L2 environment by means of spending time at the

place where the L2 is used in daily life. Thus, ways to help learners to get exposed to the target language at their own home country is, according to Schmitt (2000), to read more. By reading authentic materials, learners can greatly increase their vocabulary repertoire.

From the views on the teaching and learning vocabulary above, it is agreeable that there can be either direct/explicit or indirect/incidental approaches to it. One interesting fact found from above is that collocation is included as a part of vocabulary teaching. The empirical evidence is shown in studies by Balcı and Çakır (2012) and Rahimi and Momeni (2012). Both studies revealed that teaching vocabulary through collocations results in a better learning of the words than using traditional techniques. This method of teaching also increases retention of new vocabulary items. Although it is unclear how collocational knowledge is acquired, it is quite certain that it is not easy to achieve. This aspect of collocation, therefore, still clearly distinguishes native speakers from nonnative speakers (Wray, 2002; Hoey, 2007).

2.1.3 Lexical Approach and Lexical Items

Lewis (1993). The approach derives from the communicative approach to language learning. The emphasis of the approach is on acquiring extensive words and their combinations. Lewis claims that words do not exist in isolation in that not any words can be placed in any parts of a sentence even though it is grammatically correct. For this point, Lewis claims that "language is grammaticalized lexis, not lexicalized grammar" (1993, p. vi). This means that lexis is more important than grammar in creating meaning. Lexical approach distinguishes between vocabulary and lexis by

which vocabulary refers to a single unit of words whereas lexis refers to word combinations that learners store in their mental lexicon. Lexical approach puts special attention directly to collocations and expressions that include institutionalized utterances and sentence frames and heads. On this point, Lewis states that we deliberatively think of collocations, and to present them in our expressions instead of individual words. This means rather than trying to break things into smaller pieces, we have a conscious effort to see things in larger and more holistic ways (Lewis, 1997).

Research studies by Nattinger and DeCarrico (1992) and Sinclair (1991) suggest that there is more lexical patterning of collocation in language than previously expected. It is found that words act less as individual units and more as part of lexical phrases. This phenomenon reflects how the mind is likely to "chunk" language in order to make it easier to process. Warren (2005) also claims that collocations should be viewed as multiword lexical items with form-meaning pairing in specific contexts that fulfill communicative functions. Gyllstad (2013) states in response to this point that if lexical items such as collocations are accepted as a part of everyone's vocabulary, then we need to start thinking of ways of incorporating lexical items larger than single words into measures of vocabulary size.

According to Jackson and Zé Amvela (2007), 'lexis' is originated from Greek means 'word'. This leads to the word 'lexicology' to mean the study of lexis, which refers to the stock of words in a given language. The words 'vocabulary', 'lexis', and lexicon' may be considered as synonyms. However, each of them conveys slightly different sense. 'Vocabulary' is more colloquial. 'Lexicon' is more academic and technical. 'Lexis' is in between the other two. 'Lexical item' or 'lexeme', according to

Crystal (1995), is a "unit of lexical meaning, which exists regardless of any inflectional endings it may have or the number of words it may contain" (p. 74). It is a basic unit of meaning. Their examples can be seen on the dictionary as the headwords in a dictionary are all lexemes. Sinclair, Jones, and Daley (2004) also define a lexical item as a language unit that indicates a specific area of meaning which is unique in terms of co-occurring patterns. A lexeme or lexical item may consist of one or more words. According to Lewis (2002b), lexical items are arbitrary which means they are simply the consensus of what has been institutionalized, the use of the language that has been agreed upon by the group of users, chosen from what could be used, and actual use as opposed to theoretically possible language. Thus, each community group is likely to develop its own way of communication to be understood particularly among the members of the community. For example, people from another part of a country may not understand when they hear people from the other parts speaking.

Hanks (2013) explains that lexis or word may denote any of the following six concepts: (1) a *type* which refers to a unique spelling form; (2) a *token* which is a single occurrence of a lexical type; (3) a *lemma* or *lexeme* which refers to all forms of each word; (4) a *phraseme* or *multiword expression* which has particular meaning; (5) a lexical entry which include lexemes, phrasemes and some partial items; and (6) any of items 1 to 3 including or excluding of proper names. For example, in a sentence below

He came he saw he kicked a ball, I come I see he kicks the bucket.

There are 16 tokens, which are the total number of words in the sentence. There are 12 types, which represent different form of words. There are 9 lemmas, which are root form of each word. There is one phraseme or multiword expression, kick the bucket.

Hank's view on lexis is in agreement with Hill's (2000) which claims that 'a central feature of lexis is collocation" (p. 47).

To this point, another evidence of relationship between vocabulary and collocation is represented. This is because collocation is closely related to '*lexical item*' as well as '*phraseme*' or '*multiword expression*'. In that collocation is one kind of lexical item as well as of phraseme or multiword expression. For example, from the sentence above, the word '*kick*' tends to co-occur with the words '*ball*' and '*bucket*'. Thus collocation has been an integral part of a language all along, only given less attention than that of single unit of vocabulary.

2.1.4 Formulaic Language

Formulaic language has long been recognized mainly in terms of idioms because they have easily noticeable forms and meanings which are not represented by the combinations (Schmitt, 2010). As more research has been conducted on formulaic language, it is found to be the core characteristic of language. Idioms are found in all kinds of texts including children's books. The frequency can be higher in genre specific corpora such as meetings, TV shows, magazines, and news. Apart from idioms, there are many other types of formulaic language. The difference among them is dependent on degree of fixedness, institutionalism/conventionality, and opacity/non-compositionality. The lack of uniformity leads to different terminologies used other than formulaic language. Wray (2002) uses the term 'formulaic sequences' and found over 50 terms for it such as chunks, formulaic speech, multi-word units, collocations, formulas, prefabricated routines, conventionalized forms, holophrases, and ready-made utterances. According to Henriksen (2013), collocations are "a subset of formulaic sequences (FSs)" (p.29). Many scholars in the field namely Barfield and

Gyllstad (2009); Nation (2001); Schmitt (2004); Wood (2010); Wray, (2002) claim that FSs are the central of communicative competence.

Formulaic language, according to Kuiper (1996), has two underlying properties, which are: 1) the units of formulaic language are not only any sequence of words, but phrases; and 2) they are lexical items exactly like other lexical items such as words, and with the same properties as words would have if they are phrases. The term 'lexical phrases' is used by Nattinger and DeCarrico (1992) when examining the relationship of formulaic language and their functional usage. When exploring the relationships between two-word pairs, the term 'collocations' is used. The terms 'prefabricated expressions' and 'chunks' are used when focusing on the holistic storage of the forms.

From the above views on formulaic language, it is revealed that collocation is closely related to this type of language as being a part of it. This is especially close with the use as described by Nattinger and DeCarrico (1992) in relation to the present study as it intended to look at formulaic language of two-word pair, which they specify as collocation. Besides, in the linguistics literature, the recurrent combinations of lexical items are often referred to as collocations or formulaic speech (Bonk, 2000).

2.1.5 Mental Lexicon

The term *mental lexicon* or *mental dictionary*, according to Takač (2008), is only a reminiscent of a traditional printed dictionary because it refers to a collection of lexical items. The difference is that a printed dictionary is static, limited, and likely to become outdated, while the mental lexicon is more complex and has more efficient organization. Words in the mind seem to be connected into semantic networks with the strongest links involving coordination and collocation. In Krashen's (1987) term,

mental lexicon is mostly acquired rather than formally learned. Our mental lexicon is larger than previously recognized and very few of lexical items we know were consciously learned (Lewis, 2002b). Mental lexicon, according to Hulstijn (2000), is "a memory system in which a vast number of words, accumulated in the course of time, has been stored" (p. 210).

According to McCarthy (1990), the mind plays a role in language development and general linguistic behavior through the three processes of input, storage, and retrieval. In terms of input, children learn their mother tongue through listening produced by people around them before starting to produce the language. For second language learners, they usually deal with spoken and written form of the language at the same time from the beginning. Through listening, learners' minds familiarize themselves with various aspects of the language. In terms of storage, native speakers are likely to store words in their minds according to the spelling patterns as well as the organization into semantically related families. In terms of retrieval, this involves with receptive knowledge and productive knowledge. Receptive retrieval is related to how the mind manages input to match with the right sound and orthographic patterns and their associated meanings. Productive retrieval, meanwhile, has to be in given forms that match their meanings. These forms can be simple words, derived words and compounds, fixed collocations, and other multiword units. The retrieval process is believed to be useful for both native-speakers and second language (L2) learners in producing the language with less effort and time.

Skehan (1998) agrees with the processes of language learning and producing provided by McCarthy above. However, he gives emphasis to the importance of noticing. The processes suggested are shown in Figure 2.1 below.

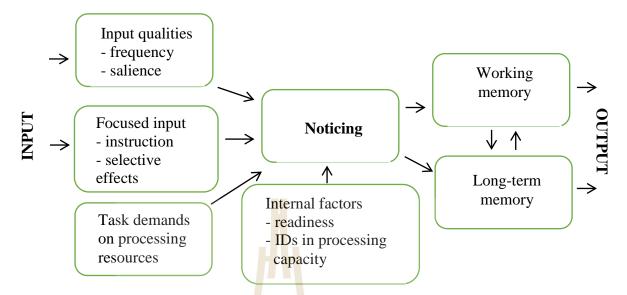

Figure 2.1 Skehan's (1998) language learning processes with emphasis on noticing

It is evident that mental lexicon has a role to play in effective production of a language with less effort. Therefore, raising L2 learners' awareness through the notion of noticing as well as increasing the size of their storage of collocations should bring a positive outcome to their proficiency (Farrokh, 2012). One way of doing this is by applying corpus tools to extract collocations out of a sample corpus of a particular genre which the present study has attempted to do.

2.2 Collocations

This part focuses on collocations which is the important element of the present study. The definitions given by a number of scholars in the field are explored. Then, the review on classifications and types of collocations is provided. The identification of collocations and the importance of collocations are presented as well as the teaching of collocations. The last part depicts the information on the test of collocation knowledge.

2.2.1 Definitions of Collocation

There are various definitions given by various scholars on collocations. Firth (1957) defines collocation as 'the company words keep' – their relationships with other words, and 'the way words combine in predictable ways'. Hill (2000) also defines collocation as 'a predictable combination of words'. If words collocate, they are co-selected by the speaker or writer and they are not a chance co-occurrence (Cheng, 2012). Collocations are sets of two or more words which appear together more frequently than their individual frequencies would lead us to expect (Hoey, 1991; Jones & Sinclair, 1974). Nattinger and DeCarrico (1992) identify collocations as unmarked choices of expression 'co-occurring lexical items that have not been assigned particular pragmatic functions by pragmatic competence'.

Collocation, according to Carter (1998), is "a term used to describe a group of words which occur repeatedly in a language" (p. 51). Collocation can be either grammatical or lexical. Schmitt (2000) gives the definition of collocation as 'the tendency of two or more words to co-occur in discourse' (p. 76). Schmitt (2000) also adds that collocation is one of the eight types of word knowledge introduced by Nation. Later Schmitt (2010) further gives more reflection on collocation that works on collocations mainly look at the relationships between two-word pairs. However, he suggests two key elements to the notion of collocation: words co-occur together and the varying degrees of exclusivity (Schmitt, 2000). The example he gives is the word 'blonde' which can go exclusively with the word 'hair', but not with the words like 'paint' or 'wallpaper'.

Nation (2001) defines the term 'collocation' as a group of words that belong together, either because they commonly occur together or because the meaning of the

group is not obvious from the meaning of the parts. There are two criteria for identifying a collocation: words frequently co-occur and some degree of semantic unpredictability as a result of the co-occurring. Lewis (2002b) also gives the definition to 'collocations' as "those combinations of words which occur naturally with greater than random frequency" (p. 25). He also adds that collocations co-occur, but not all words which co-occur are collocations. Collocation is about words which co-occur, not ideas or concepts.

Similar to Nation's, Paltridge (2006) defines collocation as associations between vocabulary items which have a tendency to co-occur such as the combinations of adjectives and nouns, verbs and nouns and others. These combinations have expectancy relations in that they tend to be predictable for particular pairs. Jackson and Zé Amvela (2007) define collocation as "a structural or syntagmatic relation, to meaning relations that a word contracts with other words occurring in the same sentence or text" (p. 131). Collocation is closely related to meaning arising from predictable co-occurrence. According to Bennett (2010), collocation is "the statistical tendency of words to co-occur" (p. 8). She explains that when one word is used, there is a high statistical probability that a certain word or words will occur alongside of it.

Apart from definitions given above, Gledhill (2000) defines the term 'collocation' into three ways according to three different perspectives: 1) Halliday's statistical/textual view; 2) the semantic/syntactic tradition in lexicology, and 3) the discoursal/rhetorical model from discourse analysis. The details of each perspective are presented below.

In terms of **the statistical/textual perspective**, collocations have often been defined statistically in corpus-based studies, following M. A. K. Halliday, who frames collocation in terms of statistical probability and co-occurrence. The core focus of this perspective is that it is "the syntagmatic association of lexical items, quantifiable, textually, as the probability that there will occur at n removes (a distance of n lexical items) from an item x, the items a, b, c ..." (Halliday, 1961, p. 276). Therefore, any given item enters into a range of collocation will be ranged from more to less probable.

Gledhill (2000) further explains that a collocate can simply be seen as any word which co-occurs within an arbitrarily determined distance or *span* of a central word or *node*. Collocation is thus considered to be the frequency with which collocates co-occur with one node relative to their frequency of collocation with other nodes. From the point of view of many corpus linguists, all that separates collocation from mere word co-occurrence is the statistical level at which the researcher is happy to say that the co-occurrence is not accidental. This approach is also 'textual' in that it relies solely on the ability of the computer program to analyze large amounts of computer-readable texts.

Gledhill (2000) concludes that this perspective essentially emphasizes collocation as co-occurrence and recurrence of words in a language. The notion of statistical collocation is fundamental to Halliday's theory of discourse. The textual view of collocation also emphasizes the fact that collocations are the result of reformulations and paraphrases which have developed throughout the length of a text. A textual collocation is likely to have a specific textual function or may occur in a rather restricted set of contexts.

In terms of **the semantic/syntactic tradition**, collocation is defined as a more abstract relationship between words, without reference to frequency of occurrence or probability, shifting the emphasis therefore from the textual co-occurrence of an expression to its potential for lexical combinability. The standard definition of collocations in this perspective is given by Benson (1989, p. 85) as "fixed recurrent combinations of words in which each word basically retains its meaning." Mel'čuk (1995), however, defines collocation as "a semantic function operating between two or more words in which one of the words keeps its 'normal' meaning" (p.182). Van der Wouden (1997) claims that idioms and collocations share some properties such as how they are formed and their role in a language. What divides the two, however, is the meaning after the combination. In that the meaning is completely changed is an idiom, while the meaning of individual words remains or is not totally changed is a collocation.

In terms of **the discoursal/rhetorical perspective**, some scholars (Moon, 1987; Fernando, 1996; Fillmore & Atkins 1994; Kay & Fillmore, 1999) believe that collocation can also be determined based on its performance in the language use. For distinguishing collocations from idioms, the notion of marked and unmarked is applied. For example, 'to get sacked' and 'to be fired' are more marked than 'to lose one's job'. Thus, according to this perspective, collocation is those combinations with less marked in comparison to that of idioms.

Although the concept of collocation is very diverse, Gledhill (2000) summarizes that all of the approaches converge on an important and recognizable phenomenon, the 'familiar recurrent expression'. Instead of arguing the case for one specific viewpoint, he sees each as compatible and relevant at different points. Since

the main purpose of his book is to analyze a large corpus of texts, the 'statistical/textual' perspective is the most appropriate approach to be adopted in the first stages of corpus analysis. For the present study in which the combination of two lexical word pairs were the target to be examined based on their mutual information (MI) score with consideration on the frequency of occurrence, the most appropriate approach is the combination of the statistical/textual perspective and semantic/syntactic tradition.

In summary, the definitions of collocation given by scholars are presented in Table 2.1 below.

Table 2.1 Definitions of collocation given by scholars

| Scholars | Collocation defined | |
|--|---|--|
| J. R. Firth (1957) | the company words keep – their relationships with other words and the way words combine in predictable ways | |
| Hoey (1991); Jones & Sinclair (1974) | sets of two or more words which appear together more frequently than their individual frequencies would lead us to expect | |
| Nattinger & DeCarrico (1992) | unmarked choices of expression 'co-occurring lexical items that have not been assigned particular pragmatic functions by pragmatic competence | |
| Carter (1998) | a group of words which occur repeatedly in a language and can be either grammatical or lexical | |
| Schmitt (2000) | the tendency of two or more words to co-occur in discourse; words co-occur together with the varying degrees of exclusivity | |
| Hill (2000) | a predictable combination of words | |
| Nation (2001) | a group of words that belong together, either because they commonly occur together or because the meaning of the group is not obvious from the meaning of the parts | |
| Lewis (2002b) | those combinations of words which occur naturally with greater than random frequency; collocations co-occur, but not all words which co-occur are collocations | |

| Paltridge (2006) | associations between vocabulary items which have a tendency to co-occur such as the combinations of adjectives and nouns, verbs and nouns and others; These combinations have expectancy relations in that they tend to be predictable for particular pairs |
|-------------------------------|---|
| Jackson & Zé Amvela (2007) | a structural or syntagmatic relation, to meaning relations that a word contracts with other words occurring in the same sentence or |
| Bennett (2010) | the statistical tendency of words to co-occur |
| Cheng (2012) | If words collocate, they are co-selected by the speaker or writer and they are not a chance co-occurrence |

From Table 2.1 above showing definitions of collocation given by scholars, there are some similarities and differences among them. The similarities are mainly the combinations of two or more words. The varieties among them are those additional details given such as the co-occurrence happens repeatedly, naturally, predictably, structurally or syntagmatically, statistically, and selectively. However, it may be concluded that collocation is the co-occurrence of words which is predictable as they have tendency to occur together and are naturally co-selected by native speakers. Lexical collocation in the present study then refers to the co-occurrence of two lexical words found in the SCNRA which tend to occur naturally with statistical significance in terms of their association.

2.2.2 Classifications of Collocation

Carter (1998) categorized collocation according to the lexical patterns into three groups: collocational restriction, syntactic structure, and semantic opacity. The details of each group are shown as follows:

1) Collocational restriction

This group consists of four sub-groups: unrestricted collocation, semirestricted collocation, familiar collocation, and restricted collocation.

- 1.1) Unrestricted collocation: this refers to the capacity of particular lexical items to co-occur with a wide range of items. Most core vocabulary belongs to this category. For example, the adjective 'bright' can co-occur with a number of other words such as light, color, sun, future, and smile. The verb 'run' can co-occur with business, errands, shop, risk, and late.
- 1.2) Semi-restricted collocation: this group refers to lexical patterns in which a number of items which can be substituted in different syntactic slots are more determined. For example, the noun 'harbor' can co-occur with doubt, grudges, uncertainty, and suspicion.
- 1.3) Familiar collocation: this group refers to the combinations between words which keep regular company with each other. For example, *unrequited love*, *unmitigated disaster*, *readily admit*, and *lukewarm reception*.
- 1.4) Restricted collocation: this group refers to the combinations between words are generally more fixed and closed. For example, *stark naked* and *pitch black*. A range of syntactic patterns are involved in this category. For example, *consider seriously, lean meat, soft water, gin and tonic*, and *accept defeat*. Those combinations which are irreversible binomials such as *cash and carry, ups and downs, hit and miss*, and *swings and roundabouts* are also included in this category.

As shown above, we can see collocations on the continuum of restrictions of combinations. The less restriction on words combinations resulted in variation of combinations, while the more restriction on words to co-occur limits words to form collocations which resulted in less variation in the combinations.

2) Syntactic structure

This group consists of three sub-groups: flexible, regular with certain constraints, and irregular.

- 2.1) Flexible: this sub-group refers to those flexible combinations between words. For example, *break somebody's heart* and *nice/good/great to see you*.
- 2.2) Regular with certain constraints: this sub-group refers to those combinations between words with certain limitations. For example, *to drop a brick*, *to smell a rat*, and *we'll now take questions from the floor*.
- 2.3) Irregular: this sub-group refers to the combinations with no fixed patterns. For example, to go one better, to be good friends with somebody, to hold true, to go it alone, and the more the merrier.

This group slightly differs from the first group on restriction as it looks at the structure of the combinations. Flexible structure enables the combinations to have high variations. Regular with certain constraints limits words to co-occur. Irregular structure, however, does not necessarily limit words to be combined, only their unpredictable patterns that may cause some confusion.

3) Semantic opacity

This group consists of four sub-groups: transparent, semi-idioms/metaphor/idiomatic similes, semi-transparent, and opaque.

- 3.1) Transparent: this sub-group refers to those combinations with clear meanings such as *long time*, *no see*; *when all is said and done*; *honesty is the best policy*; *we're just good friends*.
- 3.2) Semi-idioms/metaphor/idiomatic similes: this sub-group refers to those combinations which can be used in either direct or indirect meanings such as we are all in the same boat; an open-door policy; a fat salary; as sober as a judge.

- 3.3) Semi-transparent: this sub-group refers to the combinations with meanings that are related to other things such as *the business really took off*; *to get round somebody*; *a watched pot never boils*; *a skyscraper*; *there's more here than meets the eye*; *bumper to bumper traffic*.
- 3.4) Opaque: this sub-group refers to the combinations with meanings are unclear without contexts and totally unclear. There are two groups under this category: overt and covert. Overt refers to the combinations which meanings can be interpreted with sufficient contextual or cultural knowledge. For example, *O.K.*; *right on*; *yuk*; and *bottoms up*. Covert refers to the combinations which meanings cannot directly interpret from the words. For example, *to be on the wagon*; *to be on the ball*; *to carry the can*; and *to kick the bucket*.

This group can be put on the continuum of meaning from clear to unclear with transparent is placed on the one end and opaque is on the other. The combinations with transparent meaning are likely to produce collocations with clear meaning which can be understood right away with no need of interpretation. For the combinations with opaque meaning, on the other hand, interpretation with the context is needed to understand them.

Nation (2001) suggests that the most effective way classifies collocations using a set of scales into ten scales as follows:

1. Frequency of co-occurrence: The scale ranges from 'frequently occurring together' to 'infrequently occurring together'. This can be done by doing computer-based study of corpora.

- 2. Adjacency: Collocates can occur next to each other or separated by variable words or phrases. Thus, the scale ranges from 'next to each other' to 'separated by several items'.
- 3. Grammatically connected: Collocates normally occur within the same sentence as a part of a grammatical construction. Sometimes, however, it is possible for the items within the same text without grammatical connection to each other but in a lexical cohesion relationship as collocates. The scale ranges from 'grammatical connected' to 'grammatical unconnected'. For example, 'silk' often occurs with a color as in 'Her uniform was of rich raw silk in a shade which matched with her hair'. According to Kennedy (1998 as cited in Nation, 2001), 'silk' and 'shade' is considered as collocates without a strong grammatical connection.
- 4. Grammatically structured: There are some cases that can be classified as 'grammatical connected', but cannot be a collocation that takes account of the major divisions that would be made in analyzing a clause. In this case, the grammatical structure criterion can be applied using a list of permitted structures (Kjellmer, 1982). The scale for this type ranges from 'well structured' to 'loosely structured'. For example, 'although he', 'of the', and 'but too' are not considered as collocations although they are likely to co-occur frequently.
- 5. Grammatically uniqueness: There are some collocations that are grammatically unique. The scale for this type ranges from 'grammatically unique' to 'grammatically regular' with patterned exceptions as the mid-point. For example, 'hell for leather' is considered grammatically unique, while 'go to bed/town' is grammatically regular.

- 6. Grammatically fossilization: There are collocations that do not allow any changes in word order, some allow small changes, and some allow substantial changes. For example, 'kick the bucket' cannot be changed to 'the bucket is kicked'. The scale for this type ranges from 'no grammatical variation' to 'changes in part of speech', with 'inflectional change' as a mid-point.
- 7. Collocational specialization: Some collocates only occur together. Some consist of one item that only occurs in the presence of the other item, but the other item is not under the same restriction. Some collocations consist of items that can also occur with a range of other collocates. This phenomenon is called by Aisenstadt (1981) as collocational specialization 'restricted connectivity'. For example, 'kith and kin' the word 'kith' is limited to this phrase. The scale ranges from 'always mutually co-occurring' to 'all occurring in a range of collocations' with 'one bound item' as the mid-point.
- 8. Lexical fossilization: There are some collocations with collocates that cannot be replaced by other words, but some other can with words of related meaning. Sinclair (1987) calls it 'internal lexical variation'. The fossilization of combinations leads the combinations to be idioms with fixed and unchangeable words to be combined such as 'a bird's eye view'. Those with 'internal lexical variation' are the combinations that allow some variation of words to be combined such as 'last year', 'last week', and 'last night'. The scale ranges from 'unchangeable' to 'allowing substitution in all parts' with 'allowing substitution in one part' as the mid-point.
- 9. Semantic opaqueness: The most idiomatic collocations are those the meaning of the whole cannot be drawn from their combinations. For example, 'kick

the bucket' and 'for good'. The scale for this type ranges from 'semantically opaque' to 'semantically transparent'.

10. *Uniqueness of meaning*: Some collocations have only one meaning, while some others have more than one. For example, 'answer the door' and 'keep promise'. The scale for this type ranges from 'only one meaning' to 'several meanings' with 'related meanings' as the mid-point.

In addition to the above mentioned, Handl (2008) develops a multidimensional classification of collocations consists of semantic dimension, lexical dimension, and statistical dimension.

- 1) Semantic dimension considers the meaning of the combination as a criterion. If the meaning inside the combination is the same as the meaning outside, the expression is maximally transparent and is positioned towards the free-combination endpoint of the dimension. If the meaning outside the combination does not help in understanding the expression, it is a semantically opaque idiom.
- 2) Lexical dimension considers the size of the collocational range. The range of a node word can be obtained from the list of all the co-occurring lexical items from its concordance. A typical collocation may consist of elements chosen from a restricted set of lexical items. A node with restricted range is likely to be an idiom and a compound, while a node with a large range tends to be a collocation.
- 3) The statistical dimension considers the statistical scores as high scores show the tendency to be a collocation and low scores combination is likely to be an idiom.

The above classifications of collocation show that there are variations in doing so. However, the classification given by Handl (2008) seems to be the most comprehensive by covering almost all of the others. The semantic dimension can

cover semantic opacity given by Carter and semantic opaqueness and uniqueness of meaning given by Nation. The lexical dimension can cover collocation restrictions and syntactic structure given by Carter and those given by Nation such as adjacency, grammatically connected, grammatically structured, grammatically uniqueness, grammatically fossilization, collocational specialization, and lexical fossilization. The statistical dimension also covers frequency of co-occurrence as given by Nation.

2.2.3 Types of Collocation

According to Bahns (1993) and Schmitt (2000), there are two basic types of collocations: grammatical/syntactic collocations and semantic/lexical collocations. Grammatical collocations are those combinations between a dominant word with a grammatical word. The examples are *abide by*, *access to*, and *acquainted with*. Lexical collocation, however, usually are those combinations between two equal words such as Noun + Verb, (*e.g.*, *ball bounces*), Verb + Noun (*e.g.*, *spend money*), and Adjective + Noun (*e.g.*, *cheerful expression*). Besides these two basic types of collocations, Allerton (1984), suggests another type where the combinations are not based neither on grammatical nor lexical patterning. This type of collocation focuses on the use of *at*, *on*, or *in* before time. For example, we use *at* noon and *at* night, but *on* Monday, and *in* June. This type of collocation, however, may be considered as a kind of grammatical collocation as prepositions are the part of the combination.

Hausmann (1990 as cited in Bartsch, 2004) classifies collocations into six types with the emphasis on the combinations of content words. These six types of collocations are presented in Table 2.2 below.

Table 2.2 Types of collocations as categorized by Hausmann (1990)

| Types | Combinations | Examples |
|-------|------------------------------|--------------------------------------|
| 1 | Verb + Substantive (Object) | to tackle a problem |
| 2 | Adjective + Substantive | weak tea |
| 3 | Substantive (Subject) + Verb | the heart palpitates/throbs |
| 4 | Substantive + Substantive | a pack of dogs, a pride of lions |
| 5 | Adverb + Adjective | keenly aware |
| 6 | Verb + Adverb | hurt badly/seriously/deeply/slightly |

Hill (2000) also suggests seven types of collocations as a guide for teachers to introduce them to their students. These seven types of collocations are shown in Table 2.3 below.

Table 2.3 Types of collocations as categorized by Hill (2000)

| Types | Combinations | Examples |
|-------|---------------------------|------------------------------|
| 1 | Adjective + Noun | a huge profit |
| 2 | Noun + Noun | a pocket calculator |
| 3 | Verb + Adjective + Noun | learn a foreign language |
| 4 | Verb + Adverb | live dangerously |
| 5 | Adverb + Verb | half understand |
| 6 | Adverb + Adjective | completely soaked |
| 7 | Verb + Preposition + Noun | speak through an interpreter |

In the BBI Combinatory Dictionary of English, Benson et al. (2010) view collocations as "fixed, identifiable, non-idiomatic phrases and constructions" (p. xix). Similar to Bahns (1993) and Schmitt (2000), they categorize collocations into two major groups: grammatical and lexical collocations. Grammatical collocations are divided into 8 categories as shown in Table 2.4 as follows:

Table 2.4 Grammatical collocations as categorized by Benson et al. (2010)

| Types | Combinations | Examples |
|-------|--|--|
| G1 | Noun + preposition combinations | music in the park, breakfast in bed |
| G2 | Noun + to + infinitive | pleasure to do, right to do, need to do, promise to do |
| G3 | Noun + that clause | an agreement that she would represent us in court |
| G4 | Preposition + noun combinations | by accident, in advance |
| G5 | Adjective + preposition combination | ons angry at everyone |
| G6 | predicate adjectives + to + infinitive | ve necessary to work, ready to go |
| G7 | Adjective + that clause | afraid that, necessary that |
| G8 | 19 verb patterns | <u> </u> |
| | 1 = svo to o (or) svoo | 11 = sv possessive v-ing |
| | 2 = svo to o | 12 = sv(o) that-clause |
| | 3 = svo for o (or) svoo | 13 = svo to be c |
| | 4 = sv prep. o (or) svo prep. o | 14 = svoc |
| | 5 = sv to inf. | 15 = svoo |
| | 6 = sv inf. | 16 = sv(o)a |
| | 7 = svv-ing | 17 = sv(o) wh-word |
| | 8 = svo to inf. | 18 = s(it)vo to inf. (or) $s(it)$ vo that-clause |
| | 9 = svo inf. | 19 = svc (adjective or noun) |
| | 10 = svov-ing | เมลย์ส ^{รุง} |

Notes: s = subject; v = verb; o = object (direct or indirect); c = complement; a = adverbial (when obligatory); v-ing = verb form in -ing.

In terms of lexical collocations, there are seven categories provided as shown in Table 2.5 below.

Table 2.5 Lexical collocations as categorized by Benson et al. (2010)

| Types | Combinations | Examples |
|-------|-------------------------------------|-------------------------------|
| L1 | Verb + Noun | compose music, commit suicide |
| | Verbs denote creation and/or action | |

| L2 | Verb + Noun | dispel fear, ease tension |
|----|---|--------------------------------------|
| | Verbs mean <i>eradication</i> and/or <i>nullification</i> | |
| L3 | Adjective + Noun | reckless abandon, rough estimate |
| L4 | Noun + Verb | bombs explode, blood circulates |
| L5 | Noun + of Noun | school of whales, act of violence |
| L6 | Adverb + Adjective | deeply absorbed, hopelessly addicted |
| L7 | Verb + Adverb | affect deeply, argue heatedly |

In the present study, the researcher follows the classification suggested by Benson et al. (2010) as they provide clear distinctions between the two groups of collocations. For lexical collocations, they cover all major combinations of the parts of speech. However, the types of combinations will be reduced from seven to six by merging Benson et al.'s L1 and L2 and making a change in L5 from Noun + of Noun to simply Noun + Noun to better suit for the study as its focus is on the lexical collocations which arise from the combinations of content words. The adjusted lexical collocations to be investigated in the present study are shown in Table 2.6 below.

Table 2.6 Lexical collocations adapted from Benson et al. (2010)

| Types | Combinations 188111 | Examples |
|-------|---------------------|--------------------------------------|
| L1 | Verb + Noun | compose music, ease tension |
| L2 | Adjective + Noun | reckless abandon, rough estimate |
| L3 | Noun + Verb | bombs explode, blood circulates |
| L4 | Noun + Noun | wound dressing, road accident |
| L5 | Adverb + Adjective | deeply absorbed, hopelessly addicted |
| L6 | Verb + Adverb | affect deeply, argue heatedly |

2.2.4 Criteria for Identifying Collocation

According to Cowie and Howarth (1995), lexical phrases or collocations can be put on a 4-level scale of complexity: idiom, invariable collocation, collocation with limited choice at one point, and collocation with limited choice at two points.

At level 1, idioms represent multiword lexemes that consist of frozen collocation. This means that the combination is fixed and cannot be replaced by other words. This level has the least complexity and variation since there is no variation allowed. Therefore, if any variation is inserted into the idiom, the existence as a unit will be collapsed. For example, the idiom 'kick the bucket' which means 'to die' will no longer be an idiom if any part of it has been changed such as 'kick the pail', 'boot the bucket', or 'kick a bucket'.

In level 2, invariable collocation, variation is still not allowed. However, the meaning is different from that of idioms. The meaning of each collocation comes from the words that are combined which cause this level to be more complex. These combinations are such as 'smart phone' and 'outer space'.

For level 3, collocation with limited choice at one point, there is a slot for a limited list of words with mostly similar in meaning to be filled. This increases in both variation and complexity to the combinations. These combinations are such as 'science' can be with other words like 'computer science', 'life science', and 'health science'.

Level 4, collocation with limited choice at two points, is similar to that of level 3 only with two slots to be filled instead of one. This level has the most variation and complexity. For example, within the combination of '*urban legend*', each word can be

combined with other words such as 'urban living' or 'urban area' and 'untold legend' or 'well-known legend'.

From the criteria presented above, although both idioms and collocations lexically belong to similar group as lexical phrases or multiword lexemes, there is a clear distinction between them. The fixedness of combinations and their meanings make the combinations become idioms, while the variation allowed although in different degrees of the combinations makes collocations.

2.2.5 Importance of Collocation

According to Nation (2001), collocations play very important roles in knowing a language with three aspects. Firstly, language knowledge is collocational knowledge. This is because the stored sequences of words are the bases of learning, knowledge and use. Secondly, all fluent and appropriate language use requires collocational knowledge. To produce a native-like language, collocations play the essential role in it. Finally, many words are used in a limited set of collocations and knowing these is part of what is involved in knowing the words.

Nation (2001) also gives three major types of evidence to support the issue that collocations may be important building blocks in language use and language learning as follows:

- 1) There is the intuitive feeling that certain phrases seem to act as units.
- 2) There is the evidence from corpus studies that certain groups of words recur.
- 3) There is evidence from studies of learning and knowledge.

Kozlowski and Seymour (2003) provide a number of aspects of collocation to show its importance to the EFL/ESL learners as follows:

- 1) Collocation constitutes a large part of our mental lexicons. They explain that first language (L1) learners have the ability to store in their heads huge amounts of memorized text, addresses, telephone numbers, dates, poetry, proverbs, idioms, names and many others. The memorized information can be quickly and easily retrieved when required. In case of second language (L2) learners, they also have the ability to store language in chunks. Repetition plays the important role in memorization. Therefore, language patterns need to be heard, written, spoken and read a number of times in order for them to become fixed. As a result, recycling of language patterns through listening, speaking, reading and writing activities should be encouraged.
- 2) Collocation enables students to express ideas clearly and accurately. Students need to be shown examples of how words are used and what words they collocate with. Teachers must instruct students that words cannot be learned in isolation. For example, one of the meanings of the verb *to diet* is *to lose weight*. In order for students to use the word effectively, they need to know that a person can /diet/go on a diet/be on a diet/start a diet/, but not make a diet.
- 3) Collocation improves writing. L2 learners often produce awkward and unnatural language. Get learners to focus on awkward language and to replace it with appropriate collocations is one way of helping them to improve their writing. Writing can be improved by consistently looking for, and recording, language patterns in context to increase the chances of acquiring meaningful language.
- 4) Collocation can help students surpass that intermediate plateau. Students often become discouraged at the upper-intermediate level. This is because grammatical structure becomes less problematic for them but collocation competence

deters them from getting ahead. The ability to produce accurate and natural language makes them excited and eager to learn as well as allows them to think quickly and communicate effectively.

5) Collocation improves rhythm and stress. Once students are able to memorize longer collocation patterns, their stress and intonation become more natural. This is because the ability to produce a large number of collocations and longer patterns enables students to learn the stress patterns of whole phrases, and leads to better stress and intonation.

Bennett (2010) points out that studying collocation is important as it should give a deeper understanding of the meaning and use of a word than simply studying a single word alone. Collocations can also provide better understanding of particular words which are used in a certain phrase. She gives an example of the use of 'between' and 'through' studied by Kennedy, which found that 'between' is usually used after nouns, whereas 'through' is more frequently found after verbs (1991, p. 107, as cited in Bennett, 2010). Duan and Qin (2012) also assert that collocation is an important aspect in vocabulary acquisition as it is a universal linguistic phenomenon. Collocations as well enhance the ability of the learners to memorize new words. Farrokh (2012) stresses the importance of developing collocation knowledge of language learners in three aspects. Firstly, language knowledge requires collocational knowledge. As collocations are everywhere, a word-by-word approach is no longer effective. Secondly, efficient language acquisition requires collocational knowledge. As the human minds tend to chunk language to make it easier to process, collocations have the important role to play. Finally, fluent language use requires collocational knowledge.

From the views presented above, one quality that makes collocation important is its large coverage in a language which makes it the integral part of the language. Knowing collocation, therefore, helps shorten the process of producing the language as they are stored in the mental lexicon and are readily accessible. Another quality of collocation is that, as it is an integral part of a language, it helps in natural and appropriate production of the language. Furthermore, collocation acts as important building blocks in language use and language learning. This is because they are prevalent in the language and can be found in all genres of language use. Additionally, knowing collocation enables deeper understanding of the language more than that of knowing single words. This can also improve the main four skills of that language.

2.2.5.1 Previous Studies on Importance of Collocation

Previous research studies have confirmed that collocation knowledge plays an important role in effective use of a language of all skills. The examples of these studies are presented as follows:

Hsu (2007) investigated the use of English lexical collocations and their relation to the online writing of Taiwanese college English majors and non-English majors. 41 English major and 21 non-English major students at a national university of science and technology in southern Taiwan were the participants of the study. Each student was asked to take a 45-minute online English writing test, administered by the web-based writing program, Criterion Version 7.1 to examine the use of lexical collocations (i.e. frequency and variety). The test was also used to measure writing scores of the two groups. The findings showed that there was a significant correlation between all the students' tokens of lexical collocations and their online writing scores.

For the same category of correlation, no obvious relation was found if the English and non-English majors were considered separately. However, the significant correlation was found between the English majors' types of lexical collocations and their online writing scores in that the higher the writing scores gained indicates the more types of lexical collocations used in the writing. Thus collocational competence is important in effective communication, as writing is one of its forms.

The effect of different levels of lexical collocational density on EFL learners' reading comprehension was conducted by Sadighi and Sahragard (2013). In the study, 80 sophomore students with different levels of proficiency studying at Zand Institute of Higher Education in Shiraz, Iran were chosen based on their score distribution on a reduced TOEFL (Test of English as a Foreign Language) test constructed by Educational Testing Service (ETS, 1998). Forty participants were randomly assigned to the control group, while the other 40 were in the experimental group. Another instrument used in this study was a lexical collocation test containing two texts (as pre- and post-tests): A high and a low lexical collocational density tests designed by the researchers. A few paired/independent sample t-tests, and a two-way repeated measure were used to answer the five research questions. Results indicated that texts with high lexical collocational density influenced learners' comprehension positively. Although the instruction of lexical collocation did not have any effects on answering the vocabulary items significantly, teaching lexical collocations affected learners' reading skills positively.

The relationship between the knowledge and use of collocations and speaking proficiency was investigated by Mohajeri and Ketabi (2013). The participants were 20 Iranian EFL learners from Sadr Institute of higher Education who had passed

Testing System) test. The students took two tests: a lexical collocational test and an IELTS speaking test. Data analysis for correlations between the participants' knowledge of lexical collocations and their speaking proficiency showed a significant positive correlation between their knowledge of lexical collocation and their speaking proficiency in IELTS test. The researchers concluded that knowledge of lexical collocation play a significant role in developing speaking proficiency.

The relationship between knowledge of collocation and reading, writing, speaking and listening proficiency was also explored by Yazdandoost, AmalSaleh, and Kafipour (2014). The participants were 50 Iranian EFL graduate students of different fields of study in an English language institute in Shiraz, Iran. They took a test of both lexical and grammatical collocations to measure their collocational knowledge. Then, an IELTS sample test (Version two) was administered to find the students' reading, writing, speaking and listening proficiency. Pearson correlation coefficient illustrated a significant correlation between knowledge of collocation and reading (P = 0.724), writing (P = 0.724), listening (P = 0.706) and speaking (P = 0.885) proficiency. Regression model was conducted to find the exact contribution between variables. It indicated that knowledge of collocation can be a predicator for all four language skills. The researchers concluded that knowledge of collocation proved to be a prerequisite for successful language learning. This research confirmed the influential role of collocation knowledge in essential language learning.

From the previous studies presented above, it is evident that lexical collocations play an important role in all skills of the language. Lexical collocations can enhance writing, reading, speaking, and even listening ability of language

learners. This can lead to effective communication in general which should facilitate them with the ability to handle communication tasks of all forms effectively and confidently.

2.2.6 Teaching of Collocation

According to Nesselhauf (2005), many types of prefabricated chunks, including collocations, have not been paid adequate attention in English language teaching. However, as teaching words in chunks by means of lexical approach can enhance learners' understanding through the meaning negotiation process (Nattinger & DeCarrico, 1992; Willis & Willis, 2006), it is essential to help learners be aware of chunks, enable them to identify, organize, and record them. This is when corpusbased teaching and learning of a language has a role to play (Sinclair, 1997).

When it comes to teaching of collocation, there are some suggestions from scholars in the field who value the teaching of collocation. Hill (2000) does not perceive collocation as merely an additional aspect of language learning. Thus, it deserves to be paid attention from lesson one. He suggests four ways of teaching collocation as follows:

1) Teaching individual collocations: this is to treat collocations the same way as individual words. For example, instead paying attention to single words such as bath, friends, belief, the attention can be shifted to take a bath, make friends, strong belief, belief in God, respectively. There words such as speak, say, tell where the different among them only be made by the knowledge of their collocations. This point is supported by the studies by Bahns and Eldaw (1993); Hashemi, Azizinezhad, and Dravish (2011); Rahimi and Momeni (2012); Balcı and Çakır (2012).

- 2) Making students aware of collocation: this is to help learners become more independent on learning collocations. One way to do this is to encourage learners to think bigger than the word. For example, words that occur with *speak* may be *a foreign language*, *in public*, *fluently*, *English*. This point is supported by the study by Farrokh (2012).
- 3) Extending what students already know: this is to expand the knowledge of 2,000 words of vocabulary to cover their co-occurring words. For example, students who know a single word 'make' plus its collocations such as make a mistake/ a meal/ a complaint/ friends will use the language much better. This point is supported by the studies by Willis (1998); Balcı and Çakır (2012).
- 4) Storing collocations: this is to make effort in keeping locations being learned. Writing down and organizing them in the way that is easy to look back is recommended. This point is supported by the study by Akpınar and Bardakçı (2015).

Similarly, Nation (2001) recommends how to teach collocation according to three points on a scale (shown below in Table 2.7): idioms, at one end; allow some substitution, at the middle; and allow a lot of substitution and grammatical change and are transparent, at the other end. For the first group, idioms, they need to be dealt with as if they were single words as they are fixed in their combinations. The explanation on their history and analysis of their parts, as well as how they function in discourse should be taken into account when teaching. For the second group, allow some substitution, it is necessary to look for any patterning that occurs. Their frequency of occurrence is the starting point for dealing with the range of related collocates. The predictable collocations should be treated as part of the enrichment of the individual collocates that make them up. Some very frequent collocations can simply be

memorized and used, and later be analyzed when the learners' level of proficiency is more advanced. For the final group, allow a lot of substitutions and grammatical changes with transparency, the learning burden is dependent on the words that are combined. The learning burden is high when its form, meaning, and use are not predictable. On the other hand, the learning burden is low when its form, meaning, and use are in predictable patterns.

Table 2.7 Methods of teaching collocation on the scale of combination (Nation, 2001)

| Idioms | Allow s <mark>ome s</mark> ubstitution | Allow a lot of substitution |
|--|--|--|
| Teach as a single word, explain history, analyze the combination, and function in discourse | Look for pattern of occurrence based on frequency and predictability | Look for pattern of occurrence, the combination of words plays a major role in the learning and teaching |

Vasiljevic (2014) also suggests two main ways of how collocations should be taught: dictionary training and teaching activities. She points out that dictionaries are useful means for acquiring collocations as they often include common and useful collocations that can help learners improve their fluency, precision, and naturalness of expression. These dictionaries are such as the Cambridge Advanced Learner's Dictionary (CALD), the Oxford Collocations Dictionary for Students of English (OCDSE), and the Macmillan Collocations Dictionary. In terms of teaching activities, collocations must be a part of the planned language input. As there are a large number of lexical chunks that exist, teachers must be highly selective in their choice of target phrases, which the frequency of use is one of the most commonly criteria. Teachers must also be selective with regard to the collocation patterns to be taught. Teachers should also try to help learners remember common word combinations by making the learners aware of the linguistic motivation of multiword chunks. Review is crucial for

the acquisition of multiword chunks. Thus learners must be given opportunities to encounter the target collocations, in different contexts and in a relatively short period of time, so that memory traces can be formed. Vocabulary substitution exercises can also be useful to consolidate learners' collocation knowledge.

2.2.6.1 Previous Studies on Teaching of Collocation

There a number of previous research studies on how teaching of collocation helps EFL/ESL learners to improve their effective use of the language. These studies are conducted by scholars such as Pirmoradian and Tabatabaei (2012); Szudarski (2012); Eidian, Gorjian, and Aghvami (2013); Ördem (2013); Shooshtari and Karami (2013); and Khonamri and Roostaee (2014). The details of their studies are presented as follows:

Pirmoradian and Tabatabaei (2012) examined the effect of applying Collins Collocation Dictionary as a concordancing tool on learning lexical collocations of Iranian EFL university students. 30 students were randomly selected and then divided into two groups: experimental group and control group. A pretest was taken from both groups at the same time. In the following week concordancing practice (task1) was given to the students in the experimental group and they were asked to work with 10 lexical collocations and identify (mis)collocations. At the same time students in control group received some texts and they were asked to notice the lexical collocations. Then, posttest 1 was given to the students in both groups. In the following week, the same procedure with 10 other lexical collocations was repeated and posttest 2 was administered. The results showed that the experimental group performed better on lexical collocations than the control group and their results were significant.

The effect of meaning-focused and form-focused instructions on the acquisition of collocations was studied by Szudarski (2012). Forty-three L1 Polish EFL learners were divided into three groups: meaning-focused instruction plus focus-on-forms (MFI plus), meaning-focused instruction (MFI only) and a control group. During a three-week treatment, the two experimental groups were provided with two different types of instruction. The MFI plus group read stories that contained target collocations and additionally completed explicit exercises focused on collocational patterns, while the MFI only group read the same stories but no mention of collocations was made. The target collocations were verb-noun combinations with frequent delexical English verbs (e.g. 'give birth' or 'take a step') likely to be known by participants receptively but causing difficulty in language production. Three tests used to assess collocational competence at different levels of vocabulary mastery revealed that MFI followed by Focus on Forms (FonFs) was an effective way of enhancing learners' collocational knowledge at both the productive and receptive level, whereas MFI only does not seem to lead to much improvement.

The impact of lexical collocation instruction on learners' writing proficiency was conducted by Eidian et al. (2013). The study was conducted with 50 pre-intermediate Iranian language learners studying English at Ahvaz Islamic Azad University in Iran majoring in EFL teaching. They were selected through non-random convenient sampling procedure. They were randomly divided into experimental and control groups. The control group was taught based on conventional methods of writing instruction and the experimental group received treatment based on lexical collocation instruction in writing one paragraph essays. The design of the research was based on pre and post-test method. Pre-test was a lexical collocation test included

35 items administered before the treatment period to make the researchers sure that the groups' homogeneity on lexical knowledge in writing paragraphs. During the treatment period, five topics were administered to the participants to write one paragraph essay for each topic. A post-test on lexical collocation consisting of 35 items of multiple-choice, matching, and cloze task dealing with lexical collocations acquired through the treatment was administered. The results showed that there was a significant difference between the scores of the participants in the control and experimental groups. In addition, all the one paragraph essays of the study were analyzed through analyzing the components of writing. The results also showed that there was a significant difference between the mean scores of control and experimental groups in writing these components. Lexical collocation instruction developed the writing components of vocabulary and mechanics rather than grammar, relevance, and fluency in writing one paragraph essays.

A study to investigate whether teaching vocabulary via collocations would contribute to retention and use of English was conducted by Ördem (2013). A quasi-experimental design was formed to see whether there would be a significant difference between the treatment and control groups. Three instruments developed were conducted to 60 participants. The experimental group was taught collocations through lexical approach by means of ten different kinds of activities for ten weeks. On the other hand, the control group was taught in a traditional way, only focusing on word definitions from dictionary, antonyms, synonyms and guessing from the text. The results showed that the participants in the experimental group outperformed the ones in the control group in all of the three instruments. The study also indicated that a period of treatment and exposure to lexical collocations led the treatment group to

remember and produce the collocations in the reading courses more appropriately and less deviantly than the control group. This result showed that teaching collocations in the class systematically week by week and scaffolding learners' progress could lead to better learners who can remember and use collocations in their reading comprehension in English.

A study to explore whether receiving treatment on the use of lexical collocations affects EFL students speaking proficiency was conducted by Shooshtari and Karami (2013). In this study, 50 pre-intermediate students of Iran Language Institute, Ahvaz branch were chosen and divided into two groups. In the instruction period of ten sessions, the experimental group received instructions on five common lexical collocation patterns such as verb-adverb, noun-verb, verb-noun, adverb-adjective, and adjective-noun. Both groups took the same test before and after the treatment to measure their knowledge of collocation patterning. They also participated in a speaking task to assess their use of lexical collocation and overall oral proficiency. Results showed that the instruction of lexical collocation had a positive effect on the learners speaking proficiency and a moderate effect on their use of lexical collocations. This suggests that receiving instruction on the use of lexical collocation patterning can be effective in the enhancement of EFL students' language skills, specifically, their oral proficiency.

The effect of form-focused versus meaning-focused tasks added to an Extensive Reading (ER) program on the development of lexical collocations was conducted by Khonamri and Roostaee (2014). 41 Iranian intermediate EFL students of English language and literature at the department of foreign languages in Mazandaran University participated in this study. A reading comprehension test taken

from TOEFL was used to measure candidates' reading ability to homogenize them in terms of their entry behavior. Moreover, Word Associates Test (WAT) developed by Read (1993, 1998) was administered to examine the participants' depth of vocabulary knowledge. Participants were divided into two experimental groups: Both groups were assigned to read extensively and do some after reading tasks; the first group was given a form-focused task (FFT) while the second group worked on a meaning-focused task (MFT). The results of paired and independent sample t-tests revealed the fact that both FFT and MFT groups progressed in the interval between the pre- and post-test, but, there was not a significant difference between the effects of form-focused and meaning-focused task.

2.2.7 Tests of Collocation Knowledge

According to Bachman and Palmer (1996), the primary purpose of a language test is to provide a measure to interpret as an indicator of a test-taker's language ability. Reliability and construct validity are essential elements for this. Reliability refers to consistency of measurement. A reliable test score will be consistent across different characteristics of the test situation or the test format. Construct validity, refers to the extent to which the test scores can be interpreted as an indicator of the ability or construct being measured. To obtain construct validity, the tasks or test formats employed have to be appropriate in measuring the ability the test intends to measure. This is when test construct has a role to play. Test construct, (McNamara, 2000), refers to aspects of knowledge or skill possessed by the test takers that the test aims to measure.

As language knowledge can be viewed as a domain of information in memory available for use by the metacognitive strategies in creating and interpreting discourse

in language use (Bachman & Palmer, 1996), collocation knowledge, therefore, can also refer to a domain of information in memory in part of collocations available to use similar to other aspects of language. This includes receptive and productive knowledge. According to Nation (2001), receptive knowledge refers to ability to comprehend a language when the input is either listening or reading. Productive knowledge, on the other hand, is the ability to produce a language by means of speaking or writing. In terms of collocations, therefore, receptive knowledge is the ability to know which pair or set of words are likely to co-occur, as for using them appropriately in speaking or writing to show the productive ability.

In order to assess learners' needs and their lexical progress, Vasiljevic (2014) suggests that a test of collocation knowledge is necessary. A test, in general, can basically have a positive effect on the learners as it should help increase their awareness concerning collocations. Popular testing formats of collocation knowledge are:

- 1) L1-L2 translation;
- 2) L2 sentence cloze items;
- 3) sentence generation tasks; and
- 4) discrete tests where a node-word is provided and test takers are required to select or give one or more of its collocates such as in a matching test and a multiple choice test.

Jaén (2007) states that, similar to vocabulary tests, tests of collocation knowledge can be divided into two categories: the ones which are designed to test productive knowledge and those to test receptive knowledge. The tests of productive knowledge are those tests that intend to measure whether the learners are able to use

translation tasks where test takers have to translate the given collocations from L1 to L2 or vice versa. Another test format used is gap filling tasks where test takers are required to fill the missing pairs of the given collocations. The tests of receptive knowledge, meanwhile, are those tests that intend to explore if the test takers are able to select the most appropriate collocates of the nodes given in certain situations. The test formats are those in which alternatives are provided such as in a multiple choice format.

Hargreaves (2000) points out that tests that include the measurement of appropriate use of collocations are a standard part of University of Cambridge Local Examinations Syndicate's (UCLES) examinations. UCLES is responsible for the five Cambridge Main Suite Examinations which are the Key English Test (KET), the Preliminary English Test (PET), the First Certificate in English (FCE), the Certificate in Advanced English (CAE), and the Certificate of Proficiency in English (CPE). The examples from CPE, which tests the proficiency of the use of English, are as follows:

1. **breach**~code (of ethics)

Any doctors who the medical profession's code of ethics is severely reprimanded.

A fractures **B** cracks **C** ruptures **D** breaches

2. pursue~point

She obviously didn't want to discuss the matter so I didn't the point.

A maintain **B** follow **C** pursue **D** chase

In order to select the appropriate collocation, the learner has to know both what is possible and what is not.

Leśniewska (2006) also claims that there are possible ways of examining the learners' use of collocations. The language they produced either written or spoken may be used to look for collocations. Another way could be done by using test items either by gap-filling or multiple choice tests. Psycholinguistic tests based on word association patterns such as identifying correct pairs of collocations could also be applied to indirectly investigate the structure of the mental lexicon of learners.

According to Siyanova and Schmitt (2008), there are three general types of elicitation tools for measuring and assessing collocational competence and development of learners. The first type is in the form of written online tasks. This may be done by assigning learners to write essays or other forms of writing. The second type is off-line elicitation tools in the form of productive translation tasks, cloze format tasks, and association tasks as well as receptive multiple-choice and judgement tasks. The third type is on-line reaction tasks which are useful in tapping into the processing of collocations in language use.

Despite various formats applicable in the tests of collocation knowledge, it is agreeable that there are two categories of the test: to assess receptive and productive knowledge. A multiple-choice format seems to be used the most in testing receptive knowledge, while a gap-filling or cloze test format and a sentence generation are used in testing productive knowledge. Additionally, there has not been any standardized test designed specifically to assess the knowledge of collocations.

2.2.7.1 Previous Studies on Tests of Collocation

A translation task and a gap filling task were applied by Bahns and Eldaw (1993). Open-ended and multiple-choice cloze tests were used in a research study by Keshavarz and Salimi (2007). Ali Zarei and Baniesmaili (2010) used a fill-in the

blank test. A cloze test and a C-test were used in a research study conducted by Ebrahimi-Bazzaz, Samad, bin Ismail, and Noordin (2012). Multiple choice, gap-filling and translation of sentences containing collocations were used in the study by Miščin (2013). A gap-filling, a collocation selection test, and descriptive writing were used in a study by Suwitchanphan and Phoocharoensil (2013). A productive collocational test and a receptive collocational test were applied in the study by Torabian, Maros, and Subakir (2014). A specially designed test was used in El-Dakhs' (2015) study. The details of each study are presented as follows:

Bahns and Eldaw (1993) examined German advanced EFL students' productive knowledge of English collocations applying translation task and a gap filling task. In the translation task, it was found that more than half of the unacceptably translated lexical words were collocates. The participants did not express the collocational phrases significantly better in the translation task, where it was possible to paraphrase, than in the cloze task. The researchers concluded that one cannot easily paraphrase one's way around collocations in order to avoid the problem which they present. It was also found that some collocations in the translation task were successfully paraphrased by many students while others were rarely successfully paraphrased. Thus suggestion was that EFL teaching should concentrate on those collocations which cannot readily be paraphrased.

The relationship between the collocational competence and overall language performance was investigated by Keshavarz and Salimi (2007). The study was conducted with Iranian EFL learners using open-ended and multiple-choice cloze tests. 50-item test consisting of grammatical and lexical collocations were applied. The results of the statistical analyses showed that there was a significant relationship

between collocational competence and performance on cloze tests. Assuming the cloze test to be an effective measure, the findings point to the importance of improving EFL/ESL learners' collocational knowledge to enhance their proficiency level in the target language.

The effect of different patterns of lexical collocations on the recognition and production was examined by Ali Zarei and Baniesmaili (2010). The study was conducted with Iranian upper-intermediate learners of English. A fill-in the blank test, consisting of 111 items, was given to the participants after the recognition test in order to measure their production of the collocational patterns. Results indicated that the participants performed relatively better on adjective-noun and noun-noun combinations of lexical collocations, although the differences among the scores of the participants on the different patterns were not statistically significant. Analysis showed that the participants' performance on the noun-verb pattern was significantly poorer than the other patterns.

The relationship between the language proficiency and the knowledge of verbnoun collocations was conducted by Ebrahimi-Bazzaz et al. (2012) with Iranian EFL
learners applying a cloze test and a c-test. The language proficiency level of the
participants was scrutinized through their performance on a cloze test. A 50-item ctest was used consisting of verb noun collocations in which the verb missing but the
first letter/phoneme was provided. The results of the statistical analyses demonstrate
that there was a high positive relationship between collocational competence and
general language proficiency of learners. Therefore, it can be concluded that the c-test
is an effective measurement to assess learners' collocational competence.

Miščin (2013) used multiple choice, gap-filling and translation of sentences containing collocations to measure collocational knowledge of the first-year students of medical English. Concordance software such as Simple Concordance, Collocation Extract, TermeX were used. The corpus analysis established that the nouns "function" and "infection" occur with most verbs (30) followed by "pain" (28 verbs), "muscle" (24 verbs). 362 verbs occurred with nouns and among them the most frequent were "cause", "have", "develop", "treat", "prevent", and "produce". After that, the test was devised to examine which collocations students use with the most competence. 297 first-year students of School of Medicine in Zagreb were tested. The average result in multiple choice was 9.8 with the s = 2.0 as a standard deviation, in gap-fill 5.0 with s = 2.17, in translation into Croatian 6.7 with s = 2.10, and in translation into English 5.2 with s = 2.53. Then, glossary was made which should help future users of medical English.

Suwitchanphan and Phoocharoensil (2014) investigated how Thai EFL students studying in the regular and English programs use adjective-noun collocations as well as to find out the relationship between school curricula and collocational competence of adjective-noun using three tests: gap-filling, collocation selection test, and descriptive writing. The participants were 30 regular program students and another 30 English program students from a private secondary school in Bangkok. The main findings revealed that, in gap-filling test, the regular program participants (69.33%) scored higher than the English program participants (57.67%). The collocation selection test revealed that there was no significant difference between the curricula. The descriptive writing task showed that the regular program participants used more adjective-noun collocations (279 tokens) than did the English program

ones (211 tokens). The researchers suggested enhancing learners' collocational competence, especially adjective-noun collocations.

The possible relationship between collocational competence and vocabulary knowledge was also investigated by Torabian et al. (2014). The study was conducted with Iranian undergraduate learners. The participants were given a vocabulary test to identify their basic knowledge of common word meanings and to show how they can identify the meanings of words at different levels. Then, productive collocational test and a receptive collocational test were given to the participants to reveal the possible difference between the participants' receptive and productive knowledge. The results revealed that there was a significant difference between the receptive and productive lexical knowledge of the undergraduate learners. It was also revealed that there was a significant relationship between the collocational knowledge and the vocabulary knowledge of the learners.

The collocational competence of Arab undergraduate EFL students was examined by El-Dakhs (2015) using a specially designed test in a gap-fill and translation formats. Two exercises were used. The first exercise comprised 15 sentences with a missing verb where participants were required to fill in the missing verb per sentence in addition to an Arabic equivalent provided for the missing verb. The second exercise also consisted of 15 sentences, each with a missing adjective. Similar to the first exercise, the participants had to write the missing adjectives based on their understanding of the English sentences and the provided Arabic equivalents of the adjectives. The test was conducted to measure collocational competence of 90 Arab undergraduate learners at three academic levels in a private Saudi university was assessed. Findings showed that the collocational competence of learners was notably

unsatisfactory despite the fact that English is the medium of instruction at the University. It was also found that collocational competence improves with increased language exposure but at a slow rate, and that learners were more confident in their use of verb-noun collocations than adjective-noun collocations. The study also revealed that learners produce more intralingual than interlingual errors of collocations.

It is evident that the test of collocation can be used to measure the learners' collocational knowledge. The scores gained by the test takers should indicate their knowledge of the collocations. This will also lead to the step to be taken in response to the test results. To measure the knowledge of the learners, certain test formats have been used with the most popular are namely gap-filling, multiple-choice, and translation. In the present study, the test of collocation knowledge on collocations found in the SCNRA will be an off-line test in the form of multiple-choice, gap-filling, and a sentence writing task. These test formats are widely used by scholars in the field as seen in the previous studies. With these test formats, both receptive and productive knowledge of the test takers can be tested. Therefore, they are considered appropriate to be used to measure knowledge of nursing students on their collocations of their field extracted from the SCNRA.

2.2.8 Collocation Study in Thailand

Studies on collocations have been recently conducted in Thailand. These studies are such as by Khittikote (2011), Yumanee and Phoocharoensil (2013), Bueraheng and Laohawiriyanon (2014), Suwitchanphan and Phoocharoensil (2014), and Usen and Musigrungsi (2015).

Khittikote (2011) studied the ability to use collocations for business purposes by 50 Thai EFL learners as well as the relationship between the frequency of exposure to English and the ability to use collocations. The tests consisted of 15 multiple-choice and 10 blank-filling verb-noun collocations. A questionnaire was also used to investigate the frequency of exposure to English. The results revealed that the learners performed better in receptive test than productive one. In terms of the exposure to English, the majority of the participants had moderate level of exposure and no relationship was found with their collocation knowledge.

Yumanee and Phoocharoensil (2013) investigated collocational errors produced by 60 Thai EFL students. Two collocational tests, a 45-item multiple-choice test and an 18-item Thai-English translation test, were employed. The results showed that the students' performance in both the receptive test and the productive test appeared to be influenced by mother-tongue transfer. Additionally, it was found that the synonymy strategy, the learners' creative invention and the strategy of analogy, the paraphrasing strategy, and low knowledge of collocational skills were potential factors contributed to the high degree of collocational errors.

Bueraheng and Laohawiriyanon (2014) explored the degree of exposure to English language in relation to learners' collocational knowledge. COLLMATCH 3 receptive collocation test and productive collocation test were administered with two groups of 196 students. The results revealed that both groups of students had higher score on receptive test and International program students outperformed English major students. The researchers recommended that in order to elevate learners' productive collocational knowledge, a substantial amount of time should be devoted to learning activities such essay writing and conversation.

Suwitchanphan and Phoocharoensil (2014) investigated how Thai EFL students studying in the regular and English programs use adjective-noun collocations as well as to find out the relationship between school curricula and collocational competence of adjective-noun using three tests: gap-filling, collocation selection test, and descriptive writing. The participants were 30 regular program students and another 30 English program students from a private secondary school in Bangkok. The main findings revealed that, in gap-filling test, the regular program participants scored higher than the English program participants. The collocation selection test revealed that there was no significant difference between the curricula. The descriptive writing task showed that the regular program participants used more adjective-noun collocations than did the English program ones. The researchers suggested enhancing learners' collocational competence, especially adjective-noun collocations.

Usen and Musigrungsi (2015) explored the effectiveness of teaching collocations to grade 6 primary school students. Twelve lesson plans and a collocation test with 32 items were employed. The results revealed that students performed significantly better in the posttest. The vocabulary retention rate was 15.44 and significant. Verb-noun collocations were scored the highest, while Noun-preposition collocations were scored the lowest.

From the above samples of studies on collocations in the Thailand's context, it is evident that collocations in the specialized field have not been widely investigated, not to mention the field of nursing. The present study, therefore, should add up to what have already existed, particularly in terms of the knowledge of nursing students

on collocations in their professional field found in a sample corpus of research articles.

2.3 Corpus Studies

Since the present study involves a compilation of texts to be then analyzed using a computer software program, this section provides reviews of the literature on corpus studies. This will include definitions of corpus studies, the development of corpora and corpus studies, types of corpora, benefits of corpus studies, concordance software, corpus-based lexical analysis, identifying collocations from a corpus, as well as corpus-based language teaching and learning.

2.3.1 Definitions of Corpus and Corpus Studies

A corpus (plural: *corpora*), according to Cheng (2012), is a collection of texts that has been compiled for a particular reason. The collection of texts is based on a set of design criteria which the corpus aims to be representative. Bennett (2010) also states that a corpus is "a principled collection of authentic texts stored electronically that can be used to discover information about language that may not have been noticed through intuition alone" (p. 12). A corpus, according to Gries (2009), is a machine-readable collection of texts in either written or spoken that were produced in natural communicative settings. The collection of these texts is for two purposes. One is to be representative and balanced with respect to a particular linguistic variety or register or genre. The other is to be analyzed linguistically. A corpus can also be a large collection or database of language, incorporating stretches of discourse ranging from a few words to entire books. The applications of a corpus, according to Schmitt (2000) are: it can provide the frequency of occurrence of the words it contains; it can

reveal which words tend to co-occur; and it can illustrate the structure of the language.

It may be summarized that a corpus can be referred to a collection of texts either written or spoken of a particular genre or variety of genres for a particular purpose of analysis. A corpus is stored in an electronic form to be readable by a computer program. Corpus studies, therefore, is a study of the data in the forms and manners mentioned above. For the present study, a corpus should refer to a collection of the Sample Corpus of Nursing Research Articles (SCNRA) accessible online via SUT's library resources which is stored in an electronic form to be analyzed for identifying lexical collocations using a concordance program.

2.3.2 Development of Corpus Studies

The corpora have come to existence since the early 1900s. They were created manually with the hard work for a long period of time. The early computer based corpora were created in the 1960s. According to Schmitt (2000) and Dash (2009), the Brown University Corpus of American English (known as Brown Corpus) was the first of its kind created by Francis and Kučera at Brown University. The Brown Corpus was compiled during 1963-1964. It contains over 1 million words compiled from 500 samples of running text of edited English prose printed in the United States during the year 1961. Another corpus being created at the relatively the same time on the European counterpart was the Lancaster-Oslo/Bergen Corpus (known as the LOB Corpus). It was created by a group of scholars from the University of Lancaster, the University of Oslo, and the Norwegian Computer Centre for the Humanities. The project was based at the Department of Linguistics and Modern English Language at the Lancaster University in the United Kingdom. The LOB Corpus contained a

million words compiled from 500 British English texts from 15 categories originally published in 1961. The texts were selected by stratified random sampling. These two corpora were created by means of the written texts had to be manually typed in.

The advancement of computer technology has positive effect on the development of corpora. Once texts can be scanned and turned into text files and put into the computer, corpora can be created much easier and faster. With currently available technology, a corpus can contain hundreds of millions of words. The examples of these corpora are those of the well-known namely the COBUILD Bank of English, the British National Corpus (BNC) and the Corpus of Contemporary American English (COCA).

COBUILD, an acronym for Collins Birmingham University International Language Database, is a British research facility set up at the University of Birmingham in 1980 funded by Collins publishers. The COBUILD Bank of English is an international English language project conducted by the COBUILD team at the University of Birmingham, UK. The text bank comprises 200 million words of both written and spoken English. The whole 200 million word corpus was annotated morphologically and syntactically during 1993-94 at the Research Unit for Computational Linguistics (RUCL), University of Helsinki, using the English morphological analyzer (ENGTWOL) and English Constraint Grammar (ENGCG) parser. The project was led by Prof. John Sinclair in Birmingham, and Prof. Fred Karlsson in Helsinki. By 1997, the corpus grew to comprise over 300 million words.

The British National Corpus (BNC) is a 100 million word collection of samples of contemporary written and spoken British English from various sources. The building of the corpus began in 1991, and was completed in 1994. The latest

edition is the BNC XML Edition, released in 2007. The written part of the BNC, which cover 90% of the entire corpus, includes extracts from regional and national newspapers, specialist periodicals and journals, academic books and popular fiction, published and unpublished letters and memoranda, school and university essays, and many other kinds of text. The spoken part, cover 10% of the corpus, consists of orthographic transcriptions of unscripted informal conversations which were recorded by volunteers selected from different age, region and social classes in a demographically balanced way. The spoken language was also collected in different contexts, ranging from formal business or government meetings to radio shows and phone-ins. The BNC is distributed in a format which makes possible almost any kind of computer-based research on the nature of the language. The application areas include lexicography, natural language understanding (NLP) systems, and all branches of applied and theoretical linguistics.

The Corpus of Contemporary American English (COCA) is the largest freely-available corpus of English. The corpus was created by Mark Davies of Brigham Young University. It is used by tens of thousands of users namely linguists, teachers, translators, and other researchers every month. The corpus contains more than 450 million words of American English texts and is equally divided among spoken, fiction, popular magazines, newspapers, and academic texts. The corpus added up 20 million words each year from 1990-2012 and is also updated regularly with the most up to date texts are from summer 2012. Because of its design, it is perhaps the only corpus of English that is suitable for looking at current, ongoing changes in the English language.

2.3.3 Types of Corpora

According to Gries (2009), there are two basic types of corpora: general corpora and specific corpora. Similarly, McEnery, Xiao, and Tono (2006), also state that there are two broad types of corpora in terms of the range and the text categories compiled in the corpus: general and specialized corpora. The former are those intend to be representative and balanced for an overall language description in general. The examples of this type of corpora are such as the British National Corpus (BNC), the COBUILD Bank of English Corpus, and the Corpus of Contemporary American English (COCA). The latter are restricted to a particular variety such as written or spoken, register such as medicine or law, or genre such as newspaper or journal article.

According to Bennett (2010), there are eight types of corpora which are: generalized, specialized, learner, pedagogic, historical, parallel, comparable, and monitor. The application of each type depends on the purpose of the study. She provides more information on four types of corpora as follows:

Generalized corpora: This is the broadest type of corpus, which is often large, consists of over 10 million words, and contains a variety of language. Generalized corpora provide a whole picture of a language. Examples of this type of corpora are the British National Corpus (BNC), the American National Corpus (ANC), and the Corpus of Contemporary American English (COCA). These corpora contain written texts from various sources such as newspapers and magazines articles, works of fiction and nonfiction, as well as scholarly written journals. These corpora also contain transcripts of spoken language from both formal and informal conversations, speeches, and meetings.

Specialized corpora: This type of corpora contains texts of a certain type and aims to be a representative of the language of this type. The size can be large or small depending on the questions to be answered. Examples of specialized corpora are the Michigan Corpus of Academic Spoken English (MICASE), which contains spoken language from a university setting; the CHILDES Corpus, which compiles language used by children; the Michigan Corpus of Upper-level Student Papers (MICUSP), which is a collection of papers from various disciplines; and a medical corpus which contains language used by nurses and hospital staff. This type of corpora is used in ESP setting.

Learner corpora: This type of corpora is considered specialized corpora, only the difference is that the texts are from those produced by students who are learning the language. Learner corpora are usually tagged and can be examined to see common errors made by students. This type of corpora can be useful for the teaching and learning of the language.

Pedagogic corpora: This type of corpora contains language used in classroom settings. They can contain academic textbooks, transcripts of classroom interactions, or any other written text or spoken transcripts in an educational setting. They can be used to ensure students are learning useful language, to examine teacher-student dynamics, or as a self-reflective tool for teacher development.

Tognini Bonelli (2010), however, classifies corpora as proposed in the course of a European Union (EU) project as follows:

1) Sample corpora: As most corpora cannot represent the entire language of the all periods of time and all genres, they are often referred to as 'sample corpora'.

This type of corpus is like a 'snapshot' of particular types of text at a particular time.

The aim of this type of corpora is to present the normal linguistic features of a language or variety in approximately the proportion occurred in general use. The Brown Corpus is the example of this kind.

- 2) Corpora for comparison: Under the same design criteria and of the equal size, two or more corpora can be compared. The areas comparable are in terms of geographical and historical differences, topics, and contrastive features of the language use. In terms of geographic comparison, the examples are that of the Brown Corpus and the LOB corpus. The former represents the American English and the latter represents the British English with the texts collected in the same year of publication, 1961. In terms of historical comparison, the corpora are designed to be compared along a time dimension. This type of corpora is not very common and there are two kinds: diachronic and monitor corpora. The former represents 'snapshots' at intervals of time such as for a generation, while the latter can reveal the language change. In terms of topic, the corpora are created with texts organized by topic such as documents or reports of a particular persons or things. This type of corpora tends to be small in size. For contrastive corpora, their main components have been chosen to facilitate the study of variety. Each component, however, is designed without reference to the others. The example of this type of corpora is the Longman Grammar of Spoken and Written English compiled by Biber and his team.
- 3) Special corpora: these corpora are those compilations of texts which are not designed to be representative of a language or variety. The focus is on their extraordinariness and uniqueness of language choices. The examples of this type of corpora are the works of Shakespeare and Goethe. The first project of special corpora in turning text into electronic format is the works of St Thomas Aquinas. One of the

earliest corpora available is the Leuven Drama Corpus and Frequency List created in 1975 by L. K. Engels and colleagues at the University of Leuven.

- 4) Corpora along the time dimension: This type of corpora is similar to that of the above mentioned historical comparison corpora. There are two of them: diachronic corpora and monitor corpora. The former present 'snapshots' at intervals of time, at least a generation, the latter are compiled to investigate changes in the language of different times. The Helsinki corpus, which is a collection of English texts from c.750 to c. 1700, created at University of Helsinki, Finland, is the example of the diachronic corpus. The example of monitor corpora is the AVIATOR (Analysis of Verbal Interaction and Automatic Text Retrieval) project, which consists of an annual ten million words of *The Times* newspaper with software to detect innovations of various kinds, created at Birmingham University.
- 5) Bilingual and multilingual corpora: Bilingual corpora have been inspired by the bilingual nature of Canada with the need to have all information available in both French and English by means of electronic translation. Multilingual corpora are emerged from a relationship of translation among the constituent texts, which is also called parallel corpora. The first kind of this corpora is the Canadian Parliament's Proceedings which available in electronic format with both English and French. The example of the multilingual comparable corpus is that of the PAROLE Corpus which comprises all the official languages of the European Union. For the contrastive corpus, the corpus consists of two sub-corpora of the same language with one being translated and the other is not.
- 6) Normativeness: The Birmingham Collection of English Texts was set out to be normative by means of having adult native speakers as the originators of the texts

and having foreign learners as the recipients of the outcomes in the forms of dictionaries, grammars, and other publications. However, there has been possibility of corpus building to reassess the standards, targets, and models for non-native users and ex-colonial varieties.

- 7) Non-native speaker corpora: The language of learners can be explored much further by comparing with normative model corpora. The example of this kind of corpora is a project conducted at the Centre for English Corpus Linguistics (CECL) at the University of Louvain in Belgium.
- 8) Spoken corpora: Speech corpora are part of special corpora. The MICASE (Michigan Corpus of Academic Spoken English) corpus of academic American English is an example of this type of corpora. MICASE is created by English Language Institute at the University of Michigan and is freely accessible online.

From the reviews above, corpora can be classified into a number of types. The corpus in the present study, as it will be created solely from the selected journal articles in the field of nursing, can be well put under a specialized corpus as classification given by Bennett (2010) that it contains texts of a certain type and aims to be a representative of the language of this type, which is texts of journal articles in the field of nursing. The corpus in the present study also can be put under a sample corpus as classification given by Tognini Bonelli (2010) as it cannot represent the entire language of the all periods of time and all genres.

2.3.4 Benefits of Corpus Studies

McCarthy and O'Keeffe (2010) point out a number of benefits of corpus linguistics as follows:

1) Language teaching and learning

The corpus becomes the center of knowledge, the students take on the role of questioner and the teacher is challenged to hand over control and facilitate learning. Students' writing can be improved through the use of error tagging and follow-up student corpus investigation (Chambers & O'Sullivan, 2004). The development of learner corpora enables the learners to create and work with their own language. The studies in this area are such as by Vannestal and Lindquist (2007) entitled "Learning" English Grammar with a Corpus: Experimenting with Concordancing in a University Grammar Course"; by Belz and Vytkina (2008) entitled "The Pedagogical Mediation of a Developmental Learner Corpus for Classroom-Based Language Instruction"; and by Breyer (2009) entitled "Learning and Teaching with Corpora: Reflections by Student Teachers". The use of corpora also covers testing and teacher education. For testing, corpora can facilitate the issues of key standards and rating. In this area there are research studies by scholars such as Barker (2001) and Hasselgren (2002). Corpora can also be useful for teachers in terms of practice and professional development. A study that touches on this issue is by McCarthy (2008) entitled "Accessing and interpreting corpus information in the teacher education context".

2) Discourse analysis

Corpus linguistics enables the analysis of above-sentence discourse such as Conversation Analysis (CA), Discourse Analysis (DA), and Critical Discourse Analysis (CDA). With the application of a corpus in their study using available features such as wordlists, concordances, and key word searches, the researchers can draw on theories and applications of either CA, DA, or CDA. For example, a corpus is used to compare the turn sequence of an opening of a telephone call to a radio

station. Research studies in this area are such as by Conrad (2002), Baker and McEnery (2005), Mautner (2007), and Kim (2014).

3) Literary studies and translation studies

Corpora can be used to compare two volumes of poetry as well as the texts of movie scripts. In this manner, the researcher can assign semantic categories to key words in the corpora which are being compared to explore their stylistics. Studies in this area are such as by Bettina (2009) and Biber (2011). For the area of translation, corpora enable the comparison of patterns across languages by comparing source and target texts. Research studies in this area are such as by Baker (1999), Olohan and Baker (2000), and Kenny (2006).

4) Forensic linguistics

Corpus linguistics can be a useful tool in authenticating authorship. Cotterill (2010) notes that forensic linguists tend to refer to corpus linguistics as a tool or a resource since there is no other methods of analysis can guarantee the identification or elimination of author. Research studies in this area are such as by Coulthard (1994) and Grant (2010).

5) Pragmatics

The application of corpora in the area of pragmatics is quite slow since it usually employs data from role-plays, interviews, and Discourse Completion Tasks (DCTs). However, there has been successful use of corpora in insightful pragmatic studies. These studies are such as the investigation of individual pragmatic features such as pragmatic markers, hedging and politeness, irony, and humor. Research studies in this area are such as by Flowerdew (2002, 2004), Massimo (2011), and Vaughan and Clancy (2013).

6) Sociolinguistics, media discourses and political discourse

For sociolinguistics, it is not sufficient to work with a purely textual transcript. Thus, speaker's information such as age, gender, educational background, and geographical origin become integral parts of the analytical process. Research studies in this area are such as by Barbieri (2005, 2007, 2009), Fraser (2009), Blackwell and Fox Tree (2012), Kendall (2011), and Kendall and van Herk (2011). Media discourse, similar to CDA, tends to expose the ideologies that inform and underlie texts. Corpora can be a useful tool for working on this type of discourse. This area has been studied widely such as by Grundmann and Krishnamurthy (2010), Jaworska (2012). Tobina and Lyddy (2014), and Ju and Yeon (2015).

2.3.5 Concordance Software

Concordance software or a concordance is a computer program which is an important tool for analyzing corpora. The concordancer is capable of identifying all the instances of a target word/string in the corpus being used and show the lines of text in which they occur. The output of the target word/string, also called *node* or *keyword* is displayed at the center of the screen to make it easier to read and analyze. The output which displays the results on the screen is called a *concordance*.

According to Stubbs (1995), the concordances reveal that words may habitually collocate with other words from a definable semantic set, which may carry either positive or negative connotations. The example is the word 'cause' would typically co-occur with unpleasant things such as problems, trouble, damage, death, pain, and disease. The word 'provide', on the other hand, usually goes with positive words such as facilities, information, services, aid, assistance, and money. This phenomenon is described by the term 'collocational prosody'.

There are several concordance tools available. The following are some of them.

- 1) WordSmith Tools: It is a paid software package developed by the British linguist Mike Scott at the University of Liverpool. It was first released as version 1.0 in 1996. The current version 6.0 (Scott, 2012) was released in 2012 by the Lexical Analysis Software Limited. It is an integrated suite of programs for looking at how words behave in texts. The core areas of the software package include three modules: Concord, WordLisit, and KeyWords. The WordList tool can generate a list of all the words or word-clusters in a text, set out in alphabetical or frequency order. The concordancer, Concord, can extract any word or phrase in context and reveal what sort of company it keeps. KeyWords enable users to find the key words in a text. Each of the modules is offering a number of features available to certain other features of the analyzed text corpus. WordSmith is found to be an effective tool for research studies in the corpus studies. To mention some of them here are such as by Ruth, (2007), Ahour, Rasoulizadeh, and Behnam (2013), and Shou, Wang, and Wang (2014).
- 2) AntConc: It is a computer-based freeware corpus analysis toolkit for concordancing and text analysis developed by Laurence Anthony, a professor in the Faculty of Science and Engineering at Waseda University, Japan. The current version is 3.4.4 (Anthony, 2014). AntConc can operate on Windows, Macintosh OS X, and Linux. The software includes seven tools namely Concordance Tool, Concordance Plot Tool, File View Tool, Cluster/N-Grams, Collocates, Word List, and Keyword List.

Concordance Tool enables users to search results in a 'KWIC' (Key word in context) format. This feature allows users to explore how the search words are used in the language. Concordance Plot Tool provides search results plotted as a 'barcode' format. This provides the search results appear in target texts. File View Tool enables users to see the text of individual files. This allows more detailed investigations of the results generated in other tools of AntConc. Clusters/N-Grams displays clusters based on the search condition. In effect it summarizes the results generated in the Concordance Tool or Concordance Plot Tool. The N-Grams Tool, on the other hand, scans the entire corpus for 'N' (e.g. 1 word, 2 words, ...) length clusters. This allows users to find common expressions in a corpus. Collocates shows the collocates of a search term. This enables users to investigate non-sequential patterns in language. Word List counts all the words in the corpus and presents them in an ordered list. This helps users to easily identify which words are the most frequent in a corpus. Keyword List shows which words are unusually frequent (or infrequent) in the corpus in comparison with the words in a reference corpus. This allows users to examine characteristic words in the corpus, for example, as part of a genre or ESP study. AntCont has been widely used as a tool in corpus studies. The examples of its use are such as by Jablonkai (2009), Bal (2010), Yang (2012), and Hou (2014)

3) MonoConc Pro: This is another commercially available concordance program developed by Michael Barlow with the current version 2.2 (Barlow, 2000). It is used in the analysis of English or texts in other languages such as Spanish, French, Japanese, Chinese, etc. for linguistic or language teaching and language learning purposes. As well as providing KWIC concordance results, the software also produces wordlists and collocation information. The program is easy to use and comes with a

range of powerful features such as Context Search, Regular Expression search, Part-of-Speech Tag Search, Collocations, and Corpus Comparison. Research studies that employed MonoConc Pro are such as by Koo (2006) and Steuber (2011).

- 4) NooJ: This open-source developed by Max Silberztein (2003), is freely available at www.nooj4nlp.net. NooJ provides users with regular grammars, context-free grammars, context-sensitive grammars, unrestricted grammars as well as their graphical equivalent (finite-state, recursive, and contextual graphs) to facilitate the description of each phenomenon. NooJ's multi-layer approach allows linguists to gather elementary descriptions and describe phenomena that cross linguistic levels. NooJ can even allow users to apply sophisticated linguistic queries to large corpora in real time, in order to construct indices and concordances, annotate texts automatically, and perform semantic and statistical analyses. NooJ was used in research studies by scholars such as Cheikhrouhou (2014), Salza (2014), and Sidhom and Lambert (2014).
- 5) Sketch Engine: This concordance tools developed by Adam Kilgarriff (2015) is a commercially available program for anyone wanting to research how words behave such as how a particular word occur in a sentence or with which other words it usually co-occurs. It is a corpus software interface which works online and offers many corpora in many languages. It is a Corpus Query System incorporating word sketches, one-page, automatic, corpus-derived summaries of a word's grammatical and collocational behavior. Sketch Engine was used in research studies by scholars such as Deroey (2011), Gerow and Keane (2011), and Luzón-Marco (2011).

2.3.5.1 Previous Studies Conducted Using Concordance Software

A number of studies have been conducted using concordance software as the main tool. These studies are such as by Yang (2012); Ackermann and Chen (2013); Molavi, Koosha, and Hosseini (2014); and Gulec and Arif Gulec (2015). The details of their studies are presented as follows:

Yang (2012) investigated gender representation in an English textbook series used in Hong Kong schools. The corpus software AntConc was used to analyze the collocations of gendered terms *He/he, She/she, Man/man, Woman/woman, women, Boy/boy, Boys/boys, Girl,* and *Girls/girls* in the textbook series to examine gender stereotype. The results revealed that females were no longer regarded as delicate or weak but stronger than males. In occupational roles, females were no longer portrayed only as housewives in the family. On the other hand, the stereotyped images of males wearing shorts, jeans or shirts and females putting on skirts or dresses still exist. In addition, it was found that the male terms have more collocates and negative adjectives were only used to describe males and males were never described in terms of their physical attractiveness. The researcher gave the reason for the application of the AntConc because it is a freeware and is simple and easy to use.

MonoConc Pro 2.2 and human judgement were used as the analysis tool in a study conducted by Ackermann and Chen (2013) in developing the Academic Collocation List (ACL) from the written curricular component of the Pearson International Corpus of Academic English (PICAE) which comprises over 25 million words. The results yielded 2,468 most frequent and pedagogically relevant entries of lexical collocations. The ACL can help learners increase their collocational competence and thus their proficiency in academic English. The ACL can also

support EAP teachers in their lesson planning and provide a research tool for investigating academic language development.

The AntConc 3.2.1 concordancer program coupled with the Open American National Corpus (OANC) available online were employed to compare lexical collocations from textbook to their real use by native-speakers. This study was conducted by Molavi et al. (2014) to examine the distribution of lexical collocations in three selected series of general English textbooks through analyzing, face to face and telephone conversation scripts collected from intermediate and upper-intermediate levels. The findings suggested that a special attention has been paid to collocations noun-verb and adjective-noun combinations while the frequency of collocations in series could not be affective on learners' collocations learning. On the other hand, comparing textbooks collocations to reference corpus (OANC) showed choice of collocations in these series did not have big refers to real use of language by native speakers.

The software applications Concordance, AntConc, and Wordsmith were used in a study by Gulec and Arif Gulec (2015) to investigate verb-noun lexical collocations across the health, physical and social sciences in the written academic journals and analyzed these lexical collocations through the frequency and chi-square analysis. The study aimed to find similarities and differences between the verbs with their collocations. The results showed that there were more similarities and relationship between the health and physical sciences, while the social sciences indicated a significant difference compared to the other two. The study found 165 common verbs used across the three sciences. 12 verbs among the 165 verbs were found to be candidates verb-noun lexical collocations as prototypes. To write better,

the researchers suggested that learners need to be aware of the collocates of the verbs they know.

Although most researchers did not give reasons for selecting particular concordance software applied in their studies, it is assumable that with their compatible capacity, functions and features available, the researchers can choose the software that they see appropriate to their research. For the present study, AntConc will be used as the instrument in the present study as it is readily available online with free of charge. Most importantly the program is equipped with all the features needed for the study namely *Word List, Keyword List*, and *Collocates*. According to Kezhen (2015), AntConc has "an easy-to-use, intuitive graphical user interface and offers a powerful concordance, word and keyword frequency generator, tools for clustering and lexical bundle analysis, and a word distribution plot" (p. 62). The program also has been constantly developed by the developer with the current version 3.4.4 and version 3.5.0 is under the development.

2.3.6 Corpus-based Lexical Analysis

The corpus-based lexical analysis is the analysis of lexical words within a corpus with the help of a concordance tool. It involves the identification and analysis of "association patterns" in language use. The association patterns refer to the systematic arrangements in which linguistic features are organized in association with other linguistic and non-linguistic features (Biber, Conrad, & Reppen, 2006). The linguistic associations consist of two main categories: lexical associations and grammatical associations. The former involves the investigation of the way the linguistic feature is systematically associated with particular words. The latter

involves the investigation on how the linguistic feature is systematically associated with grammatical features in the immediate context.

There are four essential characteristics of corpus-based analysis given by Biber et al. (2006), which influence a scope and reliability of analysis. The first of these characteristics is that it is empirical. This involves the analyzing of the actual patterns of use in natural texts. The second characteristic is that it utilizes a large and principled collection of natural texts, which is known as a "corpus," as the basis for analysis. The third characteristic is that a computer program plays a major role in the analysis, using both automatic and interactive techniques. The last characteristic of corpus-based analysis is that both quantitative and qualitative analytical techniques are used.

In corpus-based lexical analysis, there are basic descriptive statistics such as frequency, token and type, word list, keyword list, and keyness. Frequency refers to the number of occurrences of each element that can be counted. For example, the number of 'token' is the frequency count from each individual word occurs in the entire corpus; while 'type' refers to the number of each type (similar or repeated) of the words that occur in the corpus. Word list refers to the list of words in a corpus which may be displayed according to the rank of frequency or alphabetically. Keyword list refers to words which are unusually frequent (or infrequent) in the corpus in comparison with the words in a reference corpus. The keywords listed from a particular corpus are likely to be good representatives of it. Keyness refers to a statistical value of the keywords measured on a basis of the value of log-likelihood or Chi-square statistics calculated from the frequency in the study corpus compared with the frequency in the reference corpus (Scott, 2012).

Another important aspect to take into consideration in corpus-based lexical analysis, particularly with the study of collocations, is statistical measures of lexical association. Hunston (2002) and Biber et al. (2006) suggest two statistical measures: the Mutual Information (MI) score and the t-score.

MI score: the MI score or MI index, according to Biber et al. (2006), indicates the strength of association between two words. The measurement is based on the likelihood of two words co-occurring within a specific span of words. The MI score is calculated by comparing the probability of ability of observing the two words together with the probability of observing each word independently based on the words' frequency. A score 0 indicates no relationship between the words. The higher the score, the stronger the association strength between the words. Normally collocate pairs with high frequency tend to have a high MI score. However, this is not always the case.

T-score: according to Biber et al. (2006), it indicates how the collocate pairs are used differently instead of how they associate. T-score measures the degrees of words that are more likely to co-occur with one particular word rather than with another. The differences in the collocates can indicate the differences in the use of the words. To find out the t-score, the pair words have to be identified. Then the frequencies of the collocates for each word are analyzed and compared to each other. Collocates with large positive t-scores tend to appear with the first word, and collocates with a large negative t-scores tend to appear with the second word.

Hunston (2002) notes the important differences between MI and T-scores as follows:

- 1) MI score is a measure of strength of collocation, while t-score is a measure of certainty of collocation.
- 2) The value of an MI score does not depend on the corpus size, while the t-score does. The larger the corpus size, the more significant is for the t-score value.
- 3) MI scores can be compared across corpora, while t-scores cannot since the size of the corpus can affect the t-score.
- 4) The top collocates measured by t-score are likely to comprise information about the grammatical behavior of a word, while MI score tends to give information about lexical behavior of a word.
- 5) The collocates with highest t-scores tend to be frequent words that collocate with various other words, while the collocates with the highest MI scores tend to be less frequent words with restricted words to co-occur with.

2.3.6.1 Previous Studies on Corpus-Based Lexical Analysis

A number of studies have been conducted applying corpus-based lexical analysis. These studies are such as those conducted by Biber, Gray, and Poonpon (2011); Yang (2012); Ackermann and Chen (2013); and Parkinson (2015). The details of their studies are presented as follows:

Biber et al. (2011) conducted a critical evaluation of T-units and clausal subordination as measures of writing development arguing that these measures have not proven to be effective discriminators of language proficiency differences. They investigated 28 grammatical features in research articles in comparison with that of in real conversations. The surprising results showed that most clausal subordination measures were actually more common in conversation than academic writing. In contrast, fundamentally different kinds of grammatical complexity were common in

academic writing: complex noun phrase constituents (rather than clause constituents) and complex phrases (rather than clauses). Based on the findings, the authors hypothesize a sequence of developmental stages for student writing, proposing a radically new approach for the study of complexity in student writing development.

A study by Yang (2012), as mentioned in the previous section (2.3.5) above, investigated gender representation in an English textbook series used in Hong Kong schools. The corpus software, AntConc, was used to analyze the collocations of gendered terms He/he, She/she, Man/man, Woman/woman, women, Boy/boy, Boys/boys, Girl, and Girls/girls in the textbook series to examine gender stereotype. In terms of the association strength between words under investigation, MI scores were used as the measurement. The reason was in accordance with Hunston's (2002) view that MI scores are more appropriate as they give information about words' lexical behavior. Additionally, the size of the corpus does not affect the MI values. The results of the study revealed that females were no longer regarded as delicate or weak but stronger than males. In occupational roles, females were no longer portrayed only as housewives in the family. On the other hand, the stereotyped images of males wearing shorts, jeans or shirts and females putting on skirts or dresses still exist. In addition, it was found that the male terms have more collocates and negative adjectives were only used to describe males and males were never described in terms of their physical attractiveness. The researcher gave the reason for the application of the AntConc because it is a freeware and is simple and easy to use.

In a study by Ackermann and Chen (2013) in which they developed the Academic Collocation List (ACL) from the written curricular component of the Pearson International Corpus of Academic English (PICAE) which comprises over 25

million words, the computational analysis using MonoConc Pro 2.2 and human judgement were applied. In the analysis procedures of the study, MI score and t-score as well as the frequency were taken into account with the MI score of at least 3 and the t-score of at least 2. The results yielded 2,468 most frequent and pedagogically relevant entries of lexical collocations. The ACL can help learners increase their collocational competence and thus their proficiency in academic English. The ACL can also support EAP teachers in their lesson planning and provide a research tool for investigating academic language development.

In a study conducted by Parkinson (2015) on the use of noun-noun collocations by learners in their academic writing, three sub-corpora were created: essays written by L1 speakers of Mandarin, Spanish, and Tswana. Production of noun-noun phrases in written English by L1 Mandarin writers (a language that permits noun-noun phrases) was compared to writing by L1 Spanish writers (a language that does not allow noun-noun phrases). The MI score of 3 or more was applied in the analysis process as a significant collocation threshold. The noun-noun combinations with an MI score less than three were referred to as noun-noun phrases. The findings showed that learners whose L1 permits noun-noun phrases produced significantly more of them in English than learners whose L1 does not.

From the above mentioned review concerning corpus-based lexical analysis, apart from the four essential characteristics described by Biber et al. (2006), measurements for association strength are the indispensible. The MI and t-score are being the most used measurements in this respect with different purposes. In that the MI score tends to closely relate to lexical behavior of words, while the t-score is likely to relate to the grammatical behavior of words being investigated.

2.3.7 Identifying Collocations from a Corpus

According to Nattinger and DeCarrico (1992), a corpus consists of authentic material, full of unexpected and diverse constructions which are often treated as too peripheral or ill-formed to be of much interest of theoretical grammars. Thus, they often require unconventional categories of description. A concordancer, a computer program, can scan all these data for collocations.

Unlike syntax which deals with general classes of words and their combinations, collocations, on the other hand, describe specific lexical items and the frequency with which these items occur with other lexical items. A collocational unit consists of a 'node' that occurs with a 'span' of words on either side. The span consists of particular word classes filled by specific lexical items. If the node word occurs with a span of particular words at a frequency greater than chance would expect, the result is a collocation. The more certain words in the span are to co-occur with the node means the more fixed and idiomatic the collocation. If collocations become less fixed or more variations are allowed, this would lead to predictability lessens and meaning increases.

The identification of collocations in a corpus starts with listing all the node words with the respective spans. The next step is to delete words in the spans which occur only once, function words, and repeated but rare words that appear only because of the subject of the text. The possible collocations are those remaining words. The deleting of articles and other function words makes the resulting collocations to be only those of combinations of the four major syntactic classes such as N+N, Adj+N, Adv+Adj, Adv+V.

Church and Hanks (1989) introduce an objective measure for identifying collocation based on the mutual information (MI). By examining the 'association ratio' based on 'mutual information' gained from the probability of observing X and Y together, with the probability of observing X and Y separately. If there is a genuine association between them, the joint probability will be greater than chance. Word probabilities are calculated by counting the number of Xs and Ys in a corpus and normalizing by the size of the corpus. Joint probabilities can be calculated by counting the number of times that X is followed by Y within a span of W words and normalizing by N.

In terms of measuring the significance of collocation, McEnery et al. (2006) and Cheng (2012) suggest that apart from z-score and log likelihood, t-score and mutual information (MI) value are the two most commonly used indicators of association strength. Most concordancing software programs are also equipped with the feature for calculating the value of these two measures. Significance for the t-score is ≥ 2 and for the MI value is ≥ 3 . The difference between these two measures, according to Stubbs (1995), is that a collocate list based on the t-score is more likely to include function words than that of based on MI value. The collocations generated based on the MI value, on the other hand, is more likely to consist of lexical collocates with less function or grammatical words.

As the present study is set to examine lexical collocations in a sample corpus, MI value will be applied as a measure for the significance of the co-occurring pairs. The keywords generated from the sample corpus of each part of speech will be treated as 'nodes'. Each 'node' will be examined for its collocates with three-word 'span' on

its right side for each type of combinations. The MI value of ≥ 3 and the frequency of occurrence of ≥ 10 will be acceptable collocational strength for this study.

2.3.8 Corpus-based Language Teaching and Learning

In EFL/ESL teaching and learning, corpus linguistics with the assistance of computer technology has been increasingly interested by scholars. This part presents information concerns corpus-based language teaching and learning which includes the use of corpora in language teaching and learning and the advantages as well as disadvantages of using them in various aspects namely in teaching English for Academic Purposes (EAP), teaching and learning grammar, writing, listening, and reading.

The use of corpora, corpus-analytic tools, and corpus evidence in English language teaching and learning have been increased for the last two decades (McEnery et al., 2006; Cheng, 2010). Corpus-based language teaching is advocated by Sinclair (2004) as a new revolution in language teaching. Fligelstone (1993) indicates that there are three aims of corpus-based linguistics in teaching: teaching about, teaching to exploit, and exploiting to teach. Teaching about covers the principles and theory concerning the use of corpora. Teaching to exploit focuses on the practical, methodological aspects of corpora. Exploiting to teach involves using corpora to derive or drive teaching materials. The fourth aim is added by Renouf (1997), which is teaching to establish resources. This involves the learners in data collection, corpus design, and corpus compilation. However, with this approach of teaching, according to McEnery et al. (2006), the traditional 'three Ps' (Presentation, Practice, and Production) may no longer be applicable. The better suited approach may be the 'three Is' (Illustration, Interaction, and Induction). Illustration refers to

looking at real data. Interaction refers to discussing and sharing opinions and observations. Induction refers to making one's own rule for a particular feature, which will be refined and polished as the amount and size of the data increase.

In terms of the advantages of using corpora in language teaching and learning, according to Gavioli and Aston (2001), corpora can capture reality and are able to provide valid models for learners as they represent authentic language. They are useful to test claims based purely on intuition and motive the decisions for teaching particular linguistic features. Corpora are also a useful tool for engaging learners in the interpretive process to create models of their own (Leech, 1986). As the learners are able to access the corpus data, they become more active learners. This aspect of corpus in language learning is advocated by Johns' (1991) 'data-driven learning' or DDL. According to Samburskiy (2014), a corpus reveals register variation of a language and a complex relationship between lexicon and grammar. It also allows learners to investigate the frequency of formulaic lexical bundles in any register. However, some disadvantages are raised from the applications of corpora in the learning and teaching language. Liu (2011) found that it took times for his students to get used to the use of the corpus and how to operate it. Samburskiy (2014) found similar problem with his students. He also found that in a search beyond specific words or phrases, students have to learn special commands.

English for Academic Purposes (EAP), according to Coxhead (2010), also has benefited a great deal from corpus linguistics. Corpus tools show students the frequency of particular features of the language. As EAP is for students whose first language is not English, it is very important to them to know more about academic language in use. This is because its distinctive and highly routinized natures that can

be problematic even for native writers, let alone non-native writers (Gilquin, Granger, & Paquot, 2007). There are a number of research studies on incorporating corpora in EAP such as by Lee and Swales (2006) and Charles (2012, 2014) as shown in Table 2.8 below.

Table 2.8 Corpus-based studies in EAP

| Researcher(s) | The study | Findings |
|---------------------|---|--|
| Lee & Swales (2006) | Participants were given access to specialized corpora of academic writing and speaking. Participants compiled two written corpora: own writing and expert writing to make comparison. | The participants developed more control over their own learning. The use of corpora to compare the writings helped raise the awareness of learners on how to write better. |
| Charles (2012) | 50 students constructed and examined their own individual, discipline-specific corpora. Questionnaires were used to collect the data. | Over 90% of students found it easy to build their own corpora. Most of them were enthusiastic about working with their own corpora and agreed that their corpus helped them improve their writing and intended to use it in the future. |
| Charles (2014) | 40 international graduate students in an EAP course built and examined their own corpora of research articles in their field. One year after the course, they completed an email questionnaire. | 70% of the respondents had used their corpus with 38% used regularly (once per week or more). Most users consulted the corpus for checking grammar and lexis and 93% of them considered that corpus use had improved their academic writing. |

In terms of teaching and learning grammar, Biber and Conrad (2010) provide three reasons why corpus-based teaching and learning of grammar is encouraged. The first reason concerns frequency information. This means that a corpus can reveal grammatical features that are common or rare. An example corpus-based research found progressive aspect is more common in conversation than in other written

registers. The second reason concerns the associations between grammar and words. This means that corpus-based research has found that not every word is equally likely to occur in a given grammatical structure. The third reason is a corpus enables register comparisons. It is found that strong patterns of use in one register do not necessarily mean to occur similarly in other registers. For example, in fictions and newspapers, the verb *say* is more frequent than any other lexical verb; in conversation, the verbs *go* and *know* are as frequent as *say*; while in academic writing, the only especially frequent verb is *BE*.

Hughes (2010) has examined the use of corpus in grammar teaching. She claims that using corpus-based materials enables teachers to highlight the differences between assumptions about language structure in the abstract and what is found in the real use. There are also commercial grammar books based on corpus data available. However, with the more technological advancement, the teaching and learning in classroom in general is likely to be more teacher-led and technology-led than depending on commercially available textbooks. This also implies the increasing role of corpus-based in language teaching and learning. Research studies in this area are such as by Vannestål and Lindquist (2007), Liu (2011), Phoocharoensil (2012), Hanafiyeh and Keshi (2013), and Rapti (2013) as shown in Table 2.9 below.

Table 2.9 Corpus-based studies in teaching and learning grammar

| Researcher(s) | The study | Findings |
|------------------------------------|--|--|
| Vannestål & Lindquist (2007) | Students worked with problem- solving assignments that involved formulating their own grammar rules based on the examples they found in the corpus. A system of peer teaching was applied. | Using corpora with students requires a large amount of introduction and support as some students appreciated working with corpora, while others, especially weak students, found it difficult or boring. |

Liu (2011) The use of corpora for problem-Four themes found: (1) critical based learning/teaching of understanding about lexicogrammar in a college lexicogrammatical and broader English grammar course was language use issues, (2) awareness of the dynamic nature investigated through students' individual and group corpus of language, (3) appreciation for research projects, reflection the context/register-appropriate papers on corpus use, and use of lexicogrammar, and (4) responses to a post-study grasping of the nuances of survey. lexicogrammatical usages. Rapti (2013) 14 young learners in Greece Some students were motivated to were studied to investigate the study grammar after the impact of DDL on motivation completion of the study. The and the learning of grammar majority of the participants had acknowledged the contribution using concordance-based tasks. and potential of corpora but also ใสยเทคโนโล pointed out the difficulties when

In teaching and learning of writing, Flowerdew (2010) explores the use of corpora for enhancing students' writing. Apart from the ability of the concordance output to show grammatical and lexical features, she claims that the even more useful function of corpora in writing is they can reveal phraseological patterning such as collocations, colligations, and semantic preferences and prosodies. She states further

involved in DDL.

that the use of corpora is an ideal tool for helping learners master those phraseological patterns as they are not easily found in either dictionaries or grammars. Research studies in this issue has been conducted by scholars such as Gaskell and Cobb (2004), Yoon and Hirvela (2004), Hegelheimer (2006), and Friginal (2013), as shown in Table 2.10 below.

Table 2.10 Corpus-based studies in teaching and learning of writing

| Researcher(s) | The study | Findings |
|--------------------------|--|---|
| Gaskell & Cobb (2004) | 20 adult Chinese EFL learners assigned 10 writing assignments. Feedbacks were given with online concordance links for five typical errors. They were required to revise the text for final submission. | The participants felt their English writing skills had improved. Eight of them would continue to use concordancing as a learning tool in future. |
| Yoon & Hirvela (2004) | 23 ESL writing students participated in the study to explore their corpus use behavior and their perceptions of the strengths and weaknesses of corpora as a second language writing tool. | Overall, the students perceived the corpus approach as beneficial to the development of L2 writing skill and increased confidence toward L2 writing. |
| Hegelheimer (2006) | The use of an online resource to improve advanced-level ESL learners' writing by increasing their grammatical awareness and ability to correct their grammatical errors. | Learners were satisfied with the system applied. They also exhibited greater awareness of grammar as well as of their own mistakes. |
| Friginal (2013) | An exploratory study investigated the use of corpora to develop the research report writing skills of college-level students. | Corpus instruction contributed positively to the patterning of the frequencies and distributional data of linking adverbials, reporting verbs, and verb tenses in the students' research reports relative to the professional corpus. |

In terms of speaking and listening, Walsh (2010) states that a collection of students' spoken work can be useful to help them understand their own problems and improve their speaking skills. Other corpora of spoken language available such as MICASE are also helpful as they represent authentic use of the language. The spoken corpora show patterns and structures which are commonly found in the genre. The corpora of spoken language can also help the learners to recognize fixed expressions which are commonly used. Research studies into this area are such as by Izumi, Uchimoto, and Isahara (2004); Furui, Nakamura, Ichiba, and Iwano (2005); and Rashtchi and Afzali (2011) as shown in Table 2.11 below.

Table 2.11 Corpus-based studies in teaching and learning of speaking and listening

| Researcher(s) | The study | Findings |
|---------------------|---|---|
| Izumi et al. (2004) | A compilation of a large-scale speech corpus called "The SST Corpus", which based entirely upon the audio-recordings of an English oral proficiency interview test called the Standard Speaking Test (SST). | By using the corpus in the experiment, the recall of article errors was 35% and the precision was 48%. By adding corrected sentences and artificially-made errors, recall and precision improved to 43% and 68% |
| Furui et al. (2005) | This corpus can be exploited for automatic detection of learners' errors with a machine learning technique. The analysis and recognition of spontaneous speech using a large-scale spontaneous speech database "Corpus of Spontaneous Japanese (CSJ)". | Recognition accuracy significantly increased as a function of the size of acoustic as well as language model training data and the improvement levels off at approximately 7M words of training data. |

| Rashtchi & Afzali (2011) | 45 university students participated in a listening course employing corpus-based materials to explore whether awareness of spoken grammar features could affect learners' comprehension of real-life conversations. | The students in the experimental group who had exposed to spoken grammar through awareness raising tasks, comprehended everyday conversations much better. They also had highly positive views of spoken grammar. |
|-----------------------------|---|---|
|-----------------------------|---|---|

In terms of reading skills, as a corpus comprises authentic language from the real use, corpus-based language learning is also likely to be beneficial for the improving of the reading skills. Walsh (2010) emphasizes that with a large resource offered by a corpus, teachers can select texts to suit particular groups of learners according to their level or content. As a result, the learning potential of materials is maximized. In a study conducted by Wang, Zheng, and Cai (2015) with students in advanced English reading course. They found that students' textual analysis skills and reading comprehension ability have improved through the student's active involvement in the construction of a textbook-related corpus and the use of corpus analysis methods in the course. Apart from the study by Wang et al. (2015), there is also a study earlier by Kırkgöz (2006) as shown in Table 2.12 below.

Table 2.12 Corpus-based studies in teaching and learning of reading

| Researcher(s) | The study | Findings |
|----------------|--|---|
| Kırkgöz (2006) | The compilation of a corpus of academic texts from the disciplines of economics and business administration, as the basis for designing a lexical component of the EAP reading course and developing teaching materials. | Students became familiarized with as well as gained more lexical competence in subject-specific lexical items. The course also enabled the students to have easy access to the written academic texts in their disciplines. |

Wang et al. (2015)

The experimental study with Chinese EFL students enrolled in Advanced English Reading course to investigate learners' textual analysis skills through compiling their own corpora and conducting textual analysis using a corpus tool.

In the experimental group, students' textual analysis skills and reading comprehension ability have improved significantly.

From the above mentioned concerning corpus-based language teaching and learning, it is evident that there are a wide range of corpus-based applications in the field which cover various aspects of EFL/ESL teaching and learning. The present study, where a corpus analysis tool will be used to identify lexical collocations in the Sample Corpus of Nursing Research Articles (SCNRA), should also contribute to the teaching and learning of English particularly the lexical collocations in the field of nursing. This could also further be useful as a building block for other four skills needed for effective communication.

2.4 English for Specific Purposes (ESP)

According to Robinson (1991), ESP is normally goal directed as the learners need English for their study or work not because they want to learn the language. Therefore, ESP course is arranged based on a needs analysis to meet learners' use of the language. As learners of ESP tend to be adults with some professional knowledge, the course is organized to help them communicate with others involved in their work situations.

Dudley-Evans and St John (1998) indicate that ESP puts the emphasis of English language teaching on practical outcomes. The main purpose of ESP is to enable the learners to communicate effectively in their specific situations in which they have to be involved in either in the daily life or professional settings. They give the definition of ESP based on its two characteristics: absolute characteristics and variable characteristics as follows:

ESP defined based on absolute characteristics:

- 1) ESP is designed to meet specific needs of the learners;
- 2) ESP makes use of the underlying methodology and activities of the disciplines it serves;
- 3) ESP is centred on the language (grammar, lexis, register), skills, discourse and genres appropriate to these activities.

ESP defined based on variable characteristics:

- 1) ESP may be related to or designed for specific disciplines;
- 2) ESP may use, in specific teaching situations, a different methodology from that of general English;
- 3) ESP is likely to be designed for adult learners, either at a tertiary level institution or in a professional work situation. However, it could also be used for learners at secondary school level;
- 4) ESP is generally designed for intermediate or advanced students. Most ESP courses assume basic knowledge of the language system, but it can be used with beginners.

2.4.1 Vocabulary teaching in ESP

According to Dudley-Evans & St John (1998), point out that the teaching vocabulary of ESP follows similar principles as applied in that of general English which concerns two groups of vocabulary: vocabulary needed for comprehension and vocabulary for production. For comprehension, learners need to be able to deduce the

meaning of vocabulary from the context and the structure of the actual word. For production, learners need to find ways to store vocabulary in their mental lexicon for use when they need them. They suggest three ways to teach vocabulary in ESP in the way that should help facilitate learners' cognitive process and remember the vocabulary, which are:

1) Situational, semantic and metaphor sets

The retrieval of a vocabulary item from memory is aided by the grouping of words according to their meaning. This may be according to topic (situational sets). For example, the word 'library' associates with words such as 'book', 'shelf, 'borrow', 'read', and so on. Or may be according to chains of association (semantic sets) so that synonyms, antonyms, superordinate and subordinate terms can be taught. Teaching of metaphor also can activate learners' cognitive process.

2) Collocation and the use of corpora

Corpora enable learners to witness not only single vocabulary, but also words that frequently co-occur with other words as well as the contexts in which they occur. This is beneficial to the learners as they should understand the words better than when looking at the words without the contexts.

3) Lexical phrases

Learning vocabulary in the form of lexical phrases or chuck is another useful way help learners to better remember the words. By identifying frequently occurred phrases and their use and let learners practice the use of those chunks, the learners should improve their proficiency quickly.

2.4.2 Corpus-based Instruction and ESP

Corpus-based instruction, according to Jabbour (2001), is also referred to as corpus-based linguistics. It is the study of genre texts for the production of materials that fit a specific group of learners. It provides a rich learning environment to the learners. Corpus-based instruction is useful in three ways. Firstly, a large number of texts can be examined as one unit under the same conditions, which make it possible for generalizations. Secondly, it enables to look at language in a range of contexts, from single words to phrases, and larger units. Finally, a corpus enables to determine not only the immediate environment of a word, but also its larger context.

According to Gavioli (2005), since ESP requires teachers to equip with knowledge of English as well as other specialized disciplines, corpora of specialized texts are useful for isolating and providing indications about key lexical, grammatical or textual issues in dealing with ESP classes. She points out that applying corpusbased instruction in ESP is helpful for teachers in the way that it enables them to teach those items which do not seem adequately dealt with in traditional teaching materials.

A number of studies have been conducted by investigating corpus-based instruction (Farr, 2010; Huang, 2012; Ashouri, Arjmandi, & Rahimi, 2014; and Bardovi-Harlig, Mossman, & Su, 2017). The details of these studies are as follows:

Farr (2010) investigated the ways in which corpora have been incorporated into a language systems module on an MA in ELT program. The survey results uncovered 25 student teachers' perspectives on their experiences of using corpora as well as the potentials and problems foreseen in relation to using the approach in their careers. The findings showed there was generally a positive predisposition towards the use of corpora. These attitudes varied in relation to the projected adaptation in

ELT, and the results also showed that the real teaching scenario often did not permit the ideal of full application.

A study conducted by Huang (2012) examined whether a corpus-based instruction could deepen EFL learners' knowledge of periphrastic causatives: make, cause, and let. The participants were 47 Taiwanese undergraduates from two intact classes. One class as the experimental group received a three-month corpus-based instruction; the other as the control group had no instruction on English causatives. A pre-test was first administered to measure participants' knowledge of periphrastic causatives. Following a data-driven model of illustration – interaction – induction, the researcher as instructor conducted the instruction and took notes on students' performance. After the instruction, a post-test was given to both groups with a questionnaire on learning effects and students' feelings for corpus-based activities distributed to the experimental group. The results revealed that the experimental group improved and outperformed the control group significantly in the post-test. The questionnaire results confirmed that the instruction was effective in increasing students' knowledge of the three causatives. However, the field notes revealed learners' difficulties in using certain causatives. The author suggests that learners should attend to semantic distinctions more than syntactic structures. Clear guidance on data search and data interpretation should also be provided.

Similarly, Ashouri et al. (2014) investigated the impact of corpus-based collocation on EFL learners' collocation learning and awareness with 60 Iranian EFL learners who were chosen randomly based on their scores in an OPT exam. There were two groups, experimental and control ones. The study examined the effects of direct corpus-based collocation instruction on EFL learners' collocation learning. For

15 sessions the control group received single-item vocabulary or, the usual work of their class and the experimental group received lexical collocation instruction as treatment. The same test as post-test was given to the learners when the treatment accomplished, and after that a t-test and kolmogorov-smirnov test between the pretests and post-tests were calculated. The results demonstrated the effectiveness of the treatment. The study suggests that direct corpus-based collocation instruction can be a worthy alternative. It demonstrated that the learners, who were in the experimental group, got aware of the existence of collocations, used them and learnt them properly, and they also started to find the collocation of every other word by themselves because the treatment appealed to them.

Bardovi-Harlig et al. (2017) also compared the effect of using corpus-based materials and activities for the instruction of pragmatic routines under two conditions: implementing direct corpus searches by learners during classroom instruction and working with teacher-developed corpus-based materials. The outcome was compared to a repeated-test control group. Pragmatic routines used for agreement, disagreement, and clarification in academic English discussion are targeted. 54 students in seven intact communication classes participated. 43 students received instruction in four 50-minute lessons across two to three weeks applying input from MICASE with noticing and production activities. The corpus-materials group (N = 26) received corpus excerpts and the corpus-search group (N = 17) conducted equivalent searches. The pre- and post-tests were administered through a computer-delivered oral-production task that simulated group discussion and included 30 items: 10 agreement, 10 disagreement, and 10 clarification scenarios. The results showed a significant increase in the oral production of pragmatic routines. The corpus-materials group additionally

showed an increase in the clarity of speech acts. The corpus-search group reported engagement in self-directed searches outside the classroom, captured by a post-test questionnaire.

From the above mentioned studies concerning corpus-based instruction applied in various aspects of EFL/ESL teaching and learning, all of them yield positive and satisfactory results. Therefore, it is convincing that the present study should apply this this method of instruction since the present study is a corpus-based study from the beginning.

2.5 Pre-Experimental Research Design

According to Ary, Jacops, and Sorensen (2010), there are two research designs which are classified as pre-experimental: One-group Pretest-Posttest Design and Static Group Comparison. However, some other scholars such as DePoy and Gitlin (2011) include One-Shot Case study into the category.

One-Shot Case Study, according to DePoy and Gitlin (2011), refers to an experiment where the independent variable is introduced followed by the dependent variable is measured in only one group. This type of design is useful in answering descriptive questions such as "what happened after a phenomenon occurred. The example can be seen in the case of a course enrolled by students where there is no a pre-test administered and at the end of the course the students have to take the examination. In such case, students' scores on the examination can only tell what they learned, but cannot attribute their learning to the course.

One-Group Pretest-Posttest Design, according to Gall, Gall, and Borg (2007) and Ary et al. (2010), involves three steps: (1) administration of a pretest; (2)

implementation of the experimental treatment for participants; and (3) administration of a posttest. The effects of the experimental treatment are determined by comparing the pretest and posttest scores. This research design is appropriate when trying to change a characteristic that is very stable or resistant to change. It is justified when extraneous factors can be estimated with a high degree of certainty or assumed to be minimal or nonexistent. In this research design, history and maturation are two extraneous variables that are not able to control and may affect the treatment. The longer period of time taken between pre-test and post-test could threaten internal validity of this design.

Static Group Comparison, according to Ary et al. (2010), is a research design where two or more preexisting or intact groups are used and only one group is exposed to the experimental treatment. The flaw of this research design is that the subjects are not randomly assigned to the groups coupled with no pre-test administered. To assess the effects of the treatment, the test scores are compared between the groups. This design, as commented by Ary et al. (2010), is basically worthless since there is no randomization or matching on a pre-test applied. This leads to a doubt in the outcome whether it is a result of the experimental treatment.

From the descriptions of the three types of the pre-experimental research design given above, the second part of the present study complies with One-Group Pretest-Posttest Design.

2.6 Academic Journals and Journal Articles

This section provides information on academic journals and journal articles.

Special attention is given to those in the field of nursing. The definitions are given

including the information on journals' impact factor as well as the historical background of nursing journals and characteristics of nursing journal articles.

2.6.1 Definitions of Academic Journals and Journal Articles

An academic journal, according to Svensson and Wood (2007), serves as a communicative interface between scholars in the field of a research discipline. It is also designed as a communicative channel for scholars to reach practitioners such as executives, managers and consultants or vice versa. According to Jerz (1999), an academic journal is a form of a publication which publishes scholarly, peer-reviewed articles that are written by experts in the field. The main function of a journal is to distribute knowledge among scholars in the field and those who might be interested. 'Scholarly' denotes that each fact or opinion is documented with the exact source for the information from the outside by means of a reference is provided in the agreed manner. The article will probably be long, complex, and possibly difficult for a nonexpert to understand right away. 'Peer-reviewed' referred to selected and approved by a panel of experts. Each academic journal has a peer review board or a panel of experts that decides which submission is acceptable for publication. The review board may send a paper back to the author with suggestions for improvement. 'Written by experts' means that academic journals typically identify their contributors as professors, graduate students, or others with first-hand experience with the subject matter.

A journal article, according to University of Toronto's libraries (2015), is sometimes called a 'scientific article', a 'peer-reviewed article', or a 'scholarly research article'. Journal articles in a particular field are often referred to as 'the literature'. Journal articles are most often primary research articles. However, they

can also be review articles which have different aims and requirements. Sometimes, an article describes a new tool or method. Without background knowledge in the field, journal articles may be hard to understand; however, the readers do not need to understand an entire article to be able to get valuable information from it. Reading a journal article may also lead to a number of other journal articles on closely related topics. In terms of the structures of a journal article, according to Cargill and O'Connor (2013), the conventional format is in AIMRaD (Abstract, Introduction, Materials and Methods, Results, and Discussion), though there may be some variations.

2.6.2 Nursing Journals

According to Mason, Kennedy, Schorr, and Flanagin (2006), the first journal in the field of nursing was launched in 1953 entitled 'Nursing Research'. The journal was founded by the AJN Company and the American Association of Collegiate Schools of Nursing and its five sister organizations (the American Nurses Association, National League for Nursing Education, National Organization of Public Health Nursing, National Association of Colored Graduate Nurses, and American Association of Industrial Nurses). 'Nursing Research' became the gold standard for the profession's research journals and continues a mandate to educate nurses about research through its publication of articles, announcements of research conferences, and opportunities for research funding. In the 1970s, there were more research in the field of nursing came out. Consequently, a number of new nursing journals were launched.

According to Binger (1981), there were 40 new nursing journals launched from the mid-1960s to the end of the 1970s. The titles of these journals reflected the

specialization in the nursing profession such as *Journal of Emergency Nursing*, *Journal of Gerontological Nursing*, *Journal of Neurosurgical Nursing*, *Cardiovascular Nursing*, *Journal of Enterostomal Therapy*, and *Nephrology Nurse*. According to Mason et al. (2006), most of the journals were affiliated with a specialty nursing professional society. For nursing societies, journals act as an arena for nurses to publish specialty-specific research and clinical review articles. They also provide forums for communication on related issues among members. On the European side, In England, for example, *Nursing Standard* is the leading general nursing journal as it is the official journal of the Royal College of Nursing (RCN). Other nursing journals are such as the *Journal of Advanced Nursing*, the *Journal of Nursing Scholarship*, and *International Nursing Review*.

From a study conducted by Díaz-Membrives, Farrero-Muñoz, and Lluch-Canut (2012), there were 74 nursing journals with an Impact Factor (IF) in 2009 and increased to 91 in the following year. In 2010, 93.5% were published in English, mostly bimonthly journals (43%) and for specialties, maternity, and paediatrics were the most frequent (25%). Almost three-quarters (72.8%) of the original articles were quantitative studies performed mostly in hospitals (42%) and with patient samples (34.6%). The most frequently studied topics were "evidence-based care" (23.5%), "measuring quality care" (18.52%), and "effectiveness of nursing interventions" (14.81%). Authors were mostly from Europe and United States and the most common workplace was a university.

2.6.3 Nursing Journal Articles

According to Alexander (2011) and Oermann and Hays (2011), the most common types of nursing journal articles are: research articles, quantitative and

qualitative articles, evidence-based practice articles, quality improvement articles, clinical articles, literature reviews, case studies, and nursing narratives and exemplars.

Research articles are reports of original data, findings, and results. They summarize a study, its purpose, methods, and findings. The typical format of this type of research is the IMRD (Introduction, Methods, Results, and Discussion) format.

Quantitative and qualitative articles can be either quantitative or qualitative reports. For the former, they usually follow the IMRD format with the results and discussion parts organized according to the purposes, research questions, or hypotheses of the study. The latter are normally used to report on the investigation on patterns of particular situations or behaviors of particular population.

Evidence-based articles are used to report on the practice and evaluate the effectiveness of new approaches in patient care. In evidence-based practice, nurses identify a clinical question or problem and then search for evidence to answer that question coupled with critically appraise studies and assess the quality of the evidence.

Quality improvement articles report on the problem that led to the need for the study, population, setting, intervention, outcomes of the study, and local conditions.

An accurate and complete report is essential for this type of article since its goal is to report the situation and ways to improve it.

Clinical articles are those reports that address topics in clinical practice. They may be written for nurses across specialties or for nurses practicing in a particular clinical area. The writing format varies but normally includes a description of the patient problems and nursing interventions by means of the article is presented.

Literature reviews are articles that summarize and evaluate the previous and recent research on particular topics. This type of articles may serve as a preview for the primary research articles. Accurate and complete citations are important in this type of article.

Case studies are articles that present case reports to provide new information on nursing practice or care of patients with particular health problems through the presentation of an actual case. The articles usually begin with the reason for reporting the case and its significance for nursing practice.

Nursing narratives or Exemplars are recommended for a novice author as they are reports on a basis of a personal account that describes outstanding examples of the actions of individuals in clinical settings that benefit patient care.

The various types of nursing journal articles presented above reflect the vast area of specialties and responsibilities professional nurses have. For the present study, these types of articles will not be taken into account as a criterion for the selection as the emphasis will be put on their format. However, the well balance in terms of the specialties of the journals where the journal articles will be taken from is one of the selection criteria.

2.6.3.1 Previous Studies Conducted with Nursing Journal Articles

A study conducted by Forbes (2009) explored clinical intervention research in nursing journal articles. From the total of 517 articles, 88% (n = 455) were classified as non-clinical intervention and 12% (n = 62) as clinical intervention studies. Characteristics of intervention studies were identified which include the underpinning theory, linkage to previous (pre-clinical) work, evidence of granularity, protocol

clarity (generalizable and parsimonious), the phase of knowledge development, and evidence of safety.

Palese, Coletti, and Dante (2013) conducted a retrospective study to examine publication efficiency of nursing journals through the time occurring between data collection and manuscript publication. The articles published in the selected journals, from 1st January to 31st December 2009 were used based on the 2009 Impact Factor List of Nursing Journals published by the ISI web of Knowledge. 1152 articles were included. From the end of data collection to manuscript publication online/on paper it took an average of 981 days [CI95% 929–1032] (2.5–3 years). Meta-analysis and systematic reviews have demonstrated the fastest process, requiring an average 1.3 years and 1.9 years respectively. Case—control, cohort and quasi-experimental studies have required more time to enjoy publication in nursing journals, 4 years, 3.5 years and 3.2 years respectively. The results implied that the production time of an article from its data collection involves significant processes and skills.

Gaskin and Happell (2014) investigated 10 highest ranked nursing journal published in the 2011 based on their 5-year impact factors to (a) assess the statistical power of nursing research to detect small, medium, and large effect sizes; (b) estimate the experiment-wise Type I error rate in these studies; and (c) assess the extent to which (i) a priori power analyses, (ii) effect sizes, and (iii) confidence intervals were reported. The results suggested that the use, reporting, and interpretation of inferential statistics in nursing research needed substantial improvement. Researchers should also abandon the misleading practice of interpreting the results from inferential tests based solely on whether they are statistically significant (or not) and, instead, focus on reporting and interpreting effect sizes, confidence intervals, and significance levels.

Nursing researchers also need to conduct and report a priori power analyses, and to address the issue of Type I experiment-wise error inflation in their studies.

Currie and Chipps (2015) conducted a study to identify military nursing papers in the main databases and to describe the field of military nursing research for the period 1990-2013 in terms of research productivity, trends in topic focus, trends in authorship, and country of publication. 237 research articles were examined through Bibliometric review together with SPSS version 21. Findings revealed that the majority of publications were from America (n = 175, 73.8%) and the number of papers has increased significantly since the beginning of the second Gulf War in Iraq from 2003 onwards (n = 156, 65.8%). It also was found that there has been a shift in topic focus from professional (n = 16, 20.3%) and occupational issues (n = 17, 21.5%) pre 2003, to clinical (n = 48, 30.4%) and an increase in multidisciplinary research from 4% in 1990-1994 to 29% in 2010-2013. The researchers concluded that the military nursing research field appeared stronger than it had been in the past twenty years and had demonstrated increased transferability to other fields.

Yang (2015) has created a Nursing Academic Word List (NAWL) from a 1,006,934-word corpus called the Nursing Research Articles Corpus (NRAC), which contains 252 English nursing research articles from online resources. The study aimed to create a nursing academic word list to serve as a guide for English for Specific Purposes (ESP) instructors and material designers in English for Nursing purposes (ENP) curriculum preparation and English for Academic Purposes (EAP) textbook design, to provide further evidence for EAP researchers who are interested in producing field-specific academic word lists and to facilitate nursing students' acquisition of academic vocabulary. The 252 nursing research articles were compiled

from 21 subject areas of nursing being taught at the researcher's university. There were four criteria for selecting the journal articles: 1) in the IMRD format; 2) written by native English speakers; 3) the articles have been published between 1995 and 2011; and 4) the articles with the length between 2000 and 10,000 words. 12 articles were selected from each of 21 subject areas. The articles were collected in their electronic version with their reference lists, appendices, captions, footnotes, and acknowledgments removed. Range, a software program, was used to analyze the corpus data. Three criteria used in creating a nursing academic word list include range, frequency, and word family by which members of a word family to be included in the NAWL had to occur in at least 11 subject areas, at least 33 times in the corpus and outside the first 2,000 most frequently-occurring word families of English. Findings showed that a frequency and range-based nursing academic word list generated consists of 676 word families, which accounts for 13.64% of the coverage in the NRAC under study. The NAWL generated was believed to provide a useful academic word pool for non-native English learners who need to read and publish nursing articles in English.

The previous studies concerning journal articles in the field of nursing as mentioned above showed that there has not been studies that focus on collocation. The closest study is a Nursing Academic Word List (NAWL) conducted by Yang (2015). By focus further on collocation, as the present study intends to do, should give more insight as well as broaden the study in both fields of nursing profession and the EFL/ESL learning and teaching.

2.7 Framework of the Present Study

The present study is originated from the idea that collocation is essential for natural and appropriate use of a language and an effective communication as well as the learning of a language in general as supported by a number of scholars namely Bennett (2010), Duan and Qin (2012), Farrokh (2012), Henriksen (2013), Hill (2000), Hoey (2007), Kozlowski and Seymour (2003), Lewis (2000), Nation (2001), and Wray (2002). A corpus-based lexical analysis is a great method of identifying and extracting collocations from a sample corpus of a particular field of specialization. The case of the present study is the Sample Corpus of Nursing Research Articles (SCNRA). With the identified and listed collocations, it is believed that it would greatly benefit the teaching and learning of the collocations in the field as supported by the lexical approach (Lewis, 1993; 1997) in teaching and learning of a language. The focus of the present study is on lexical collocations adapted from the combination patterns as provided by Benson et al. (2010). Since collocation, especially lexical collocation, is closely related to vocabulary as its larger units, the present study will look at the combination of lexical words within the three-word span from the right side of the node. A pre-test of collocational knowledge constructed based on the collocations gained from the study will be administered with the fourth year nursing students at SUT. This will be followed by lessons on collocations by means of a corpus-based instruction. The post-test will be then administered to determine the effect of teaching on students' performance. The framework for the present study can be presented in diagram as shown in Figure 2.2 below.

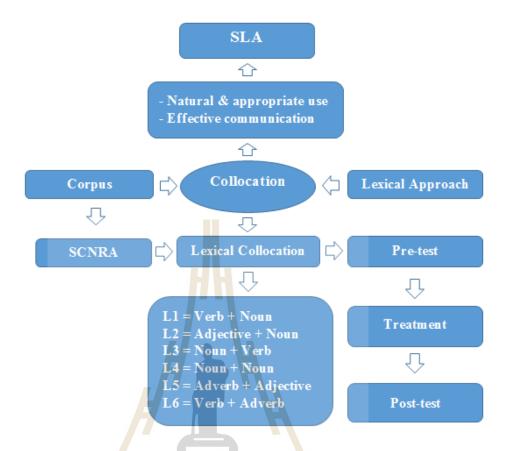

Figure 2.2 Framework for the present study

From Figure 2.2 above, the center is collocation as it is the central of the present study which is believed to lead further to natural and appropriate use of a language as well as effective communication as they are the indicators of the ultimate goal of second language acquisition (SLA). With this in mind, the present study aims to explore lexical collocations from a Sample Corpus of Nursing Research Articles (SCNRA) by means of corpus linguistics. The lexical collocations will be those adapted from that of provided by Benson et al. (2010). Following the extraction and classification of the collocations, a test of collocation knowledge will be constructed based on lexical collocations found from the study. The test will be conducted with the fourth year nursing students as a pre-test in order to evaluate their knowledge of

lexical collocations in their field. This will be followed by the lessons on collocations using a corpus-based instruction. The post-test will be conducted once the collocation lessons have completed to determine the effect of teaching on the test takers' performance.

2.8 Summary of the Chapter

This chapter presented reviews of the literature related to the present study. It started by exploring the relationship between vocabulary and SLA which involves how vocabulary and collocation are related, teaching and learning of vocabulary, lexical approach and lexical items, formulaic language, and mental lexicon. The following part was the reviews on collocations which covered the definitions, the classifications, the types, and the criteria for identification. The importance of collocation as well as the teaching, tests of collocation knowledge, and collocation study in Thailand context were also provided. The third part provided information on corpus studies which includes the definitions, the development, types, and benefits. The information on concordance software, corpus-based lexical analysis as well as corpus-based language teaching and learning were also illustrated. The fourth part provided information on ESP in relation to collocations and corpus-based instruction. The fifth part introduced pre-experimental research design. The sixth part reviewed journals and journal articles as well as nursing journal and journal articles. The last part described the framework of the present study which crystalized from the reviews of literature and the rationale of the study.

CHAPTER 3

RESEARCH METHODOLOGY

This chapter presents research methodology to be applied in this study. It starts with a research design which consists of two main parts. Then it provides in detail regarding the instruments, data collection, and data analysis for each part of the research involved in the study. The data analysis which describes how the collected data are analyzed is provided. The summary of the chapter is also given.

3.1 Research Design

According to Biber et al. (2006), a corpus-based study is a method applied for investigating "association patterns" of language in a corpus. These association patterns are either linguistic features or their varieties or texts. In terms of linguistic association, there are either lexical or grammatical associations. Lexical associations can be investigated by looking at particular words for their association with other words. Grammatical associations can be examined by looking at the grammatical constructions of the language. In terms of varieties or texts, the investigation can be on linguistic association patterns such as individual linguistic features or classes of features or co-occurrence patterns of linguistic features. Since the present study started with the investigation of lexical collocation, which is considered as a part of linguistic association patterns of a language under lexical association patterns, a corpus-based design is appropriate for this study.

As the objectives of this study were: (1) to identify and classify keywords found in the Sample Corpus of Nursing Research Articles (SCNRA) published in international journals in the field of nursing; (2) to identify and classify lexical collocations using keywords generated from the SCNRA; (3) to assess lexical collocation knowledge of nursing students based on the collocations found from the SCNRA; and 4) to provide lessons on nursing collocations and assess the effects of corpus-based instruction, this study thus consists of two main parts: the identification and classification of lexical collocations and the tests of nursing collocation knowledge of nursing students. With these two parts, the research part I provides adequate information for the first two objectives, while the research part II gives a clear conclusion regarding collocational knowledge of nursing students under investigation and the effects of corpus-based instruction on their performance by which a pre-experimental research design with One-Group-Pretest-Posttest Design was employed.

3.2 Research Part I: Identifying Lexical Collocations

This part provides the answers to Research Questions 1 and 2.

- **RQ 1**: What are the keywords in the SCNRA based on the frequency of occurrence at ≥ 50 and the keyness value at ≥ 20 ? What is the proportion according to their parts of speech?
- **RQ 2**: What are the lexical collocations of the keywords in the SCNRA? What is the proportion according to each type of combinations?

3.2.1 Research Instruments

The instruments applied in this part were research articles published in the selected nursing journals and a corpus analysis tool: a concordance software.

Nursing Journals and Nursing Research Articles

In terms of the research articles used as the data for the present study, they were those research articles published in the academic journals in the field of nursing accessible via SUT's library resources. This is important as these journals are meant to serve both academic staff and students of the Institute of Nursing at SUT. By identifying lexical collocations from the Sample Corpus of Nursing Research Articles (SCNRA), it should be directly beneficial for both academic staff and students of nursing at SUT. Regarding the availability of the journals, most of the journals accessible are as up to date as 2016. However, a few of them can provide the access of the latest issues with a few years back. From a questionnaire sent out and replied by the nursing students, these journals are recognized by the majority of the students.

A Corpus Analysis Tool

As this part of the study involves the examination of lexical collocations from the SCNRA, a concordance software is necessary. The AntConc version 3.4.4 (Anthony, 2014), which is the latest version, was used. This program has been developed by Laurence Anthony, a professor in the Faculty of Science and Engineering at Waseda University, Japan. The reasons why the AntConc has been chosen as a corpus analysis tool for the present study are:

1) AntConc is a computer-based freeware corpus analysis toolkit for concordancing and text analysis. This makes it economical and practical for anyone working with a corpus.

- 2) AntConc can operate on Windows, Macintosh OS X, and Linux.
- 3) AntConc is equipped with seven tools namely Concordance Tool, Concordance Plot Tool, File View Tool, Cluster/N-Grams, Collocates, Word List, and Keyword List. With all these available features of the program, it serves as the appropriate tool for the present study.
- 4) A number of previous studies had employed AntConc successfully as a tool. These studies are; for example, by Yang (2012) in investigating gender representation in an English textbook series used in Hong Kong schools; by Stvan (2013) in examining of the term 'stress' in naturally occurring vernacular prose; by Molavi et al. (2014) in investigating the distribution of lexical collocations in three selected series of general English textbooks; by Gulec and Arif Gulec (2015) in exploring verb-noun lexical collocations across the health, physical and social sciences in the written academic journals and analyzed these lexical collocations through the frequency and chi-square analysis; and by Getkham (2016) in investigating how linguistic devices are used to convey authorial stance in 36 Introduction sections and 36 Discussion sections of doctoral dissertations written in English by Thai students graduated in language education from different universities in the United States during the period 2008 to 2013.

From the accessibility and features the AntConc has, it can efficiently serve the purpose of this study as it can identify keywords of the sample corpus and further identify collocations of those keywords. According to Wilkinson (2012), in comparison to other tools available, AntConc is quite efficient. It is quite compatible with the best available commercial programs such as WordSmith and MonoConc Pro. The interface of the AntConc version 3.4.4 is shown in Figure 3.1 below.

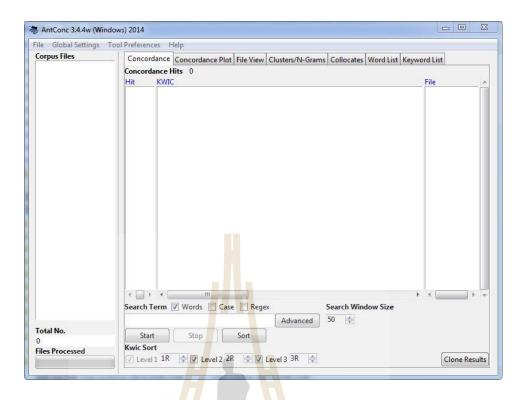

Figure 3.1 The Interface of the AntConc version 3.4.4

3.2.2 Data Collection

The data collection procedures in the first part of the present study involves the selection of nursing journals and nursing research articles as well as the compilation of the selected research articles for data analysis.

3.2.2.1 Selecting Nursing Journals and Nursing Research Articles

Since this study focuses on lexical collocations in nursing research articles, the process of selecting the research articles started with identifying journals in the field of nursing accessible via SUT's library resources. The targets of this study were nursing journals with international recognition and internationally serve researchers in the field to publish their research work. Once the journals had been selected, the articles from the latest publication available were obtained and compiled into text files ready for use with the concordance software. The latest issues of the journals

collected were as up to date as 2016. Only some of them were a few years back. The procedures of selecting the nursing journal are shown in Figure 3.2 below.

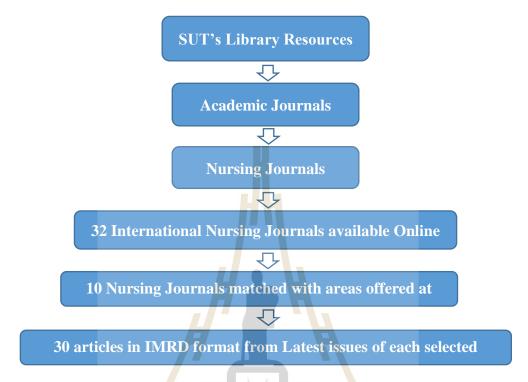

Figure 3.2 The process of selecting nursing journals from SUT's Library resources

Criteria for selecting nursing journals

As there were altogether 32 international journals accessible online via SUT's library resources (See Appendix A), 10 journals were selected for the present study. These 10 journals are purposively selected for the study based on the following criteria:

- 1) The titles which indicate the specialized areas that match with those were on offer by Institute of Nursing at SUT, which were six areas as follows:
 - (1) Nursing care of families and midwifery,
 - (2) Nursing Care of the Child and Adolescent,
 - (3) Adult and elderly nursing or Gerontological nursing,
 - (4) Community nursing,

- (5) Psychiatric nursing, and
- (6) Fundamental nursing
- 2) These journals were accessible online with full research articles in the IMRD format available either in HTML or PDF files. This is to prove the ease of assess of the journals and the research articles they contain for the academic staff and students of SUT as well as the researcher.
- 3) The selected journals were those with the Impact Factor (IF), since it indicates the popularity and credibility of the journals.
- 4) From the information gained from the fourth year nursing students of Academic year 2015 through an online questionnaire, the students recognized most of the selected journals and had read research articles from these journals.

Based on the criteria above mentioned, the selected nursing journals for the present study are listed in Table 3.1 below with their impact factors.

Table 3.1 The selected Nursing Journals with their Impact Factors

| No. | Nursing Journals Selected | IF | Areas offered at SUT |
|-----|---|---------------|---|
| 1 | Journal of Epidemiology & Community Health | 3.501 | Community health nursing |
| 2 | International Journal of Mental Health Nursing | 1.95 Tulas | Psychiatric nursing |
| 3 | Journal of Nursing Management | 1.5 | Fundamental nursing and others |
| 4 | Nursing Inquiry | 1.439 | Fundamental nursing and others |
| 5 | Journal of Family Nursing | 1.342 | Nursing care of families and midwifery |
| 6 | Clinical Nursing Research | 1.278 | Fundamental nursing and others |
| 7 | Journal of Clinical Nursing | 1.255 | Fundamental nursing and others |
| 8 | Journal of Pediatric Oncology Nursing | 0.903 | Nursing Care of the Child and Adolescent, Adult and elderly |

| 9 | Journal of Psychiatric and Mental Health Nursing | 0.844 | Psychiatric nursing |
|----|---|-------|--------------------------------|
| 10 | International Journal of Nursing | 0.98 | Fundamental nursing and others |

As shown above in Table 3.1, it is noticeable that among the 10 journals selected, there are five journals that matched with the area of Fundamental nursing and others and the other five journals matched with each of the five areas offered at the Institute of Nursing at SUT. Since six areas of nursing fields were offered with 10 journals to be selected, this was not possible to make equal representative of each area. Therefore, it is justifiable to select one journal of each of the six areas with the rest four journals selected were those journals belong to the area of Fundamental nursing and others since this area does not represent specific areas as the other five journals do.

Criteria for selecting nursing research articles

Once the journals had been selected, the research articles from those selected journals were compiled according to the following criteria:

- 1) The selected research articles were those which had been written in the appropriate proportions of IMRD (Introduction, Methods, Results, and Discussion) format with length not less than 3,000 words. The IMRD format is a format commonly used in quantitative and experiment-based research (Englander, 2014). This format of writing can also be found in the journals in the field of nursing.
- 2) From each journal, 30 research articles were selected based on the latest issues available at the time of the study being conducted. The selection started from the latest available issue of each journal. Each journal was examined for their accessibility following with their format of writing where the IMRD was the target. If

the article met the criteria, it was saved in a text file format and named for the ease of management. For the articles that did not meet with the criteria set, they were not chosen for this study. The process was repeated until 30 articles were collected for each journal. This made up the total of 300 research articles compiled for the present study.

In terms of corpus size, McEnery et al. (2006) explain that the size of the corpus needed depends on the purpose for which it is intended. Quesada (2011) points out that a corpus is big enough when, for any new learning experience added, the probability of adding a new type is so low that is negligible. This means that adding more to the size of a corpus will have little effect on the new data to be found. For the present study, as research articles have a typical length ranging from 3,000 to 10,000 words (Björk, Roos, & Lauri, 2009), the SCNRA compiled from 300 research articles comprised about 1,500,000 words. This is efficient for the investigation of lexical collocations the present study intends to achieve. With this size of the SCNRA, it is large enough to provide acceptable frequency of occurrence to the keywords as well as the co-occurrence of the collocations under investigation. The files of the research articles compiled into the SCNRA were manageable and analyzed using a concordance program, the AntConc. The details of the sample corpus in terms of the number of files are shown in Table 3.2 below.

Table 3.2 Nursing Journals with the number of research articles used in the study

| No. | Nursing Research Articles taken from | Quantity |
|-----|--|----------|
| 1 | Journal of Epidemiology & Community Health | 30 |
| 2 | International Journal of Mental Health Nursing | 30 |
| 3 | Journal of Nursing Management | 30 |
| 4 | Nursing Inquiry | 30 |

| 5 | Journal of Family Nursing | 30 |
|----|--|-----|
| 6 | Clinical Nursing Research | 30 |
| 7 | Journal of Clinical Nursing | 30 |
| 8 | Journal of Pediatric Oncology Nursing | 30 |
| 9 | Journal of Psychiatric and Mental Health Nursing | 30 |
| 10 | International Journal of Nursing Practice | 30 |
| | Total | 300 |

3.2.3 Data Analysis

The data analysis in this part involves two parts: the identifying keywords and lexical collocations generated from the keywords of the SCNRA.

3.2.3.1 Procedures in Identifying Keywords

For the present study, keywords according to the keyness value were listed for further use as nodes to identify their collocates. The number of keywords for the present study had been determined by two criteria: the keyness value and the frequency of occurrence. The keyness value set for the present study for the keywords is ≥ 20 , while the frequency of occurrence is ≥ 50 . According to Baker (2006), the higher the keyness score, the stronger the keyness of that word. The frequency of occurrence indicates how common the word is in the corpus. The identification of the keywords in the SCNRA followed the steps below:

- 1) Upload the text files onto the analysis tool, the AntConc, to form the SCNRA.
 - 2) Set preferences in 'Global Settings'.
- 3) Set preferences in 'Tool Preferences'. At this stage, under 'Collocates', MI value is selected as a statistic measure for the association strength of collocational pairs. Also, at this stage, under 'Keyword List', Reference Corpus is uploaded. For the

present study, the British National Corpus (BNC) is used as the reference corpus as it is one of the largest corpora of general English and commonly used as a reference corpus in corpus-based studies as well as the word list is readily available online.

- 4) Once all the necessary preferences are set, the analysis can be commenced. By clicking on the 'Word List' tab followed by clicking on 'Start' button, the results will reveal the numbers of types and token the SCNRA contains. The concordance software also displays the list of the words by ranking according to the frequency of occurrence.
- 5) By clicking on a 'Keyword List' tab followed by the 'Start' button, the list of keywords of the SCNRA will be revealed.

As not every word displayed on the keyword list is acceptable as keywords, for example, 'et', 'al', proper nouns, abbreviations, and acronyms can be on the keyword list, they were excluded from the list. To create the keyword list according to the set criteria, the researcher looked through the list according to their keyness ranking and manually deleted unacceptable keywords that leave the rest to become the keyword list under the set criteria which are words with the frequency of occurrence at ≥ 50 and the keyness score at ≥ 20 . Once the list of keywords had been made, they were ready for the next stage of the study, identifying collocations. These keywords were also classified and grouped according to their part of speech.

3.2.3.2 Procedures in Identifying Collocations

Once the keywords had been identified, as they were then used as the 'nodes' to further identify their collocates, the next stage of the study could be proceeded. The processes of identifying collocations in the SCNRA were in steps as follows:

- 1) Under the 'Keyword List' tab, click on the keyword acceptable to be the node, for example, the word 'Nurses'. The concordance program displays under the 'Concordance' tab to show the concordance lines the word 'Nurses' appears in the entire corpus with the frequency of occurrence.
 - 2) To find the collocates of a node, click on the 'Collocates' tab.

Before clicking on 'Start' button, there are three preferences to be set as follows:

Under 'Window Span', set as 'From 0 to 3R' as the study intended to investigate the collocates with three-word span on the right side of the nodes.

Under 'Sort by', select 'Sort by Stat' as the study gave more important to the MI score than the frequency of occurrence.

Under 'Min. Collocate Frequency', set as '10' as the study set the number of the co-occurrence of the pairs at ≥ 10 . However, the number of occurrence could be reduced in case of the number of co-occurrence did not meet the criteria that is when the frequency of occurrence is less than 10. In that case, the intention would be paid only on the MI value of the pair which the present study is set at ≥ 5 . Also, in this case, the first collocate with the highest MI value and the highest frequency of occurrence would be selected.

Once the preferences were set accordingly, click on 'Start' button.

3) After clicking on 'Start' button, the collocates of the node would be displayed if they were any. The strength of each pair of lexical collocation identified was measured on the basis of Mutual Information (MI) as provided by the AntConc. In order to measure the association strength of each pair, there is the comparison between the study corpus, the SCNRA, and the reference corpus. The reference

corpus used in this study is the British National Corpus (BNC) as it is readily available and comprises over 100 million words. It is also one of the largest corpora of general English and commonly used as a reference corpus.

The acceptable association strength of co-occurring pair is the MI value of ≥ 3 (Cheng, 2012). The frequency of the co-occurrence is one important factor to be considered. For the present study, the frequency of co-occurrence of each pair has been set at ≥ 10 as the higher rate of co-occurrence means higher the need for students of nursing to be familiar with. In case of a pair co-occurs less than 10 times but has MI value ≥ 5 , the collocate with the highest occurrence and MI value would be chosen. As well, in case of a node has more than one collocates that meet the criteria, all of them would be selected.

As the criteria set for the study that the collocates have to have the MI value at least 5 with the frequency of occurrence at least 10, not all of the words on the list may be acceptable collocates. Even those words that meet the criteria may not always eligible to be acceptable pairs. To check whether a collocate is acceptable pair of a node or not, by clicking on the word, it will show how the pair co-occur in the sample corpus. In case of no collocates with the number of occurrence of 10 or more with the MI value at least 5, the reduction of the 'Min. Collocate Frequency' could be applied. The acceptable pairs of collocations were recorded for each keywords or nodes as the results and for further analysis.

4) The process was repeated for other keywords/nodes to find their collocates.

The results of each keyword with their collocates were recorded using Microsoft Excel spreadsheet.

5) The collocations generated from the keywords or nodes found were then classified according to the types of combination. The combination patterns of the lexical collocations in the present study have been adapted from that of Benson et al. (2010). That is from the original seven combinations, the present study has adapted to six combinations. This is to create lexical collocations of two word pair on the right side of the nodes within the range of four word span. This combination is meant to help add up to single word vocabulary which should be a proper stepping stones for students to learn as the extension of the normal single unit vocabulary. The comparison between the combinations given by Benson et al. (2010) and the adapted combinations for the present study is shown in Table 3.3 below.

Table 3.3 Lexical Collocations: Benson et al. (2010) and Adapted in Comparison

| Types | Combinations by Benson et al. (2010) | Types | Combinations adapted |
|-------|--------------------------------------|-------|-----------------------------|
| L1 | Verb + Noun | | |
| L2 | Verb + Noun | L1 | Verb + Noun |
| L3 | Adjective + Noun | L2 | Adjective + Noun |
| L4 | Noun + Verb | L3 | Noun + Verb |
| L5 | Noun + of Noun | L4 | Noun + Noun |
| L6 | Adverb + Adjective | L5 | Adverb + Adjective |
| L7 | Verb + Adverb 21asınalulas | L6 | Verb + Adverb |

From Table 3.3 above, among the seven lexical collocations with the combinations developed by Benson et al. (2010), L5 combination is not in the two word combinations having 'of' between the nouns. Also for the L1 and L2, both are the combinations of Verb + Noun. In order to create lexical collocations within the range of four word span, the L5 is adapted by looking only for the combinations of Noun + Noun without having 'of' between them. In this case, however, if there is a

combination between nouns occurs within the range of four word span with 'of' in it as in Noun + of + Noun, such combination is the legitimate combination of the present study. The Verb + Noun combinations in L1 and L2 are reduced to have only one Verb + Noun combinations. This is to reduce the complexity of the combinations. Figure 3.3 below shows the process of identifying keywords and their collocates.

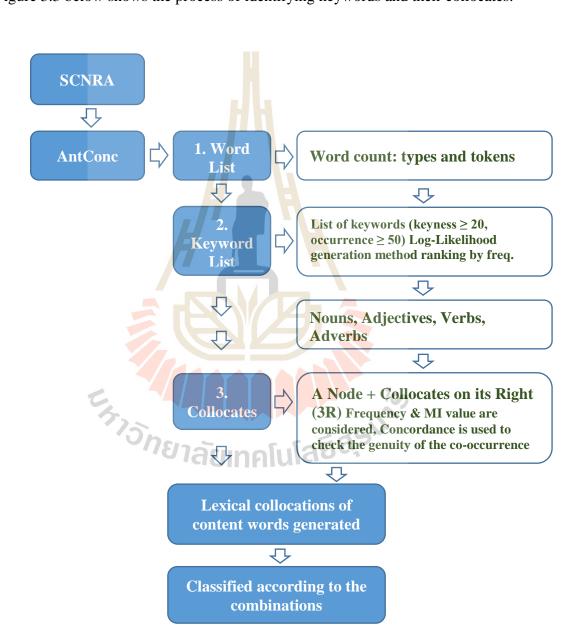

Figure 3.3 The process of identifying keywords and collocations from SCNRA

The collocations gained from the SCNRA, particularly lexical collocations, were then used for the second part of the study, the test of collocation knowledge of the fourth year nursing students at SUT.

3.2.4 Pilot Study

The objectives of the pilot study were: (1) to examine the plausibility of the research project which intends to explore lexical collocations found in a Sample Corpus of Nursing Research Articles (SCNRA), and (2) to explore whether any adjustments were necessary in order to conduct the main study successfully.

The pilot study was conducted with a sample corpus of nursing research articles compiled from 10 journals in the field of nursing intended for the main study. The pilot study was conducted by following the procedures designed for the main study, to investigate two immediate word lexical collocations. The differences are that the number of the articles used where five research articles were taken from each of the listed journals. These selected research articles were also taken from the earlier issues than research articles to be used for the main study to avoid the repetition of articles in the main study.

The sample corpus of 50 research articles from the 10 journals in the field of nursing comprises 11,517 types and 225,248 tokens. 500 keywords were selected according to the ranking of their keyness value for further analysis. When classified into categories according to the part of speech, the 500 selected keywords consist of 348 nouns (65.5%), 118 adjectives (22.2%), 58 verbs (10.9%), and 7 adverbs (1.32%)

The identified keywords were then used as 'nodes' for the next step of the study which was to find out their collocates. In the pilot study, as the lexical approach was emphasized, lexical collocations of the nodes had been explored. From the

keywords according to their parts of speech, the collocations found from the sample corpus were divided into three groups as follows: 1) lexical collocations according to the set framework; 2) collocations not according to the set framework; and 3) keywords/nodes with no collocates.

For the first group, which presents collocations the present study intends to investigate, it reveals the lexical collocations of 281 keywords or nodes that account for 52.92 percent. The second group, collocations which are not according to the set framework, comprises 174 keywords or nodes with their collocates other than lexical collocations. The majority of these collocations can be categorized as grammatical collocations. The last group, keywords or nodes with no collocates, comprises 76 keywords that account for 14.31 percent with the majority being the nouns.

From the findings gained from the pilot study, it is found that from the 500 keywords generated, the majority of them, 65.5 percent, being the nouns. The adjectives come the second place at over 22 percent. The verbs come third at over 10 percent and the adverbs are the least in number, just over 1 percent. Among the three groups categorized according to the combinations, the majority being lexical collocations with the combinations according the set framework of over 52 percent, generated from 281 keywords. The rest of the keywords give the results not according to the set framework that can be divided into two groups: grammatical collocations and words with no collocations.

As the main focus of the study is on the group of lexical collocations to further apply in the assessment of SUT nursing students' knowledge of lexical collocations, the proportion of the group with over 52 percent and 281 in number is considered large enough to meet the purpose. Although the results reveal that there are

combinations of words both within the framework and outside of the framework, all of the combinations are worth investigation as they actually occur in the real use of the language. Thus, despite the focus of the study is on the lexical collocations of the set framework, knowing other possible collocates or no collocates is still useful in effective communication and use of the language as well as the EFL/ESL learning and teaching. With the larger sample size in the main study, it is believed that the results could be slightly different and more statistically significant.

As the objectives of this pilot study were to examine the plausibility of the research project as well as to explore whether any adjustments were necessary in order to successfully conduct the main study, the results of the pilot study assured that this research project was plausible. However, there was a concern in terms of the meaningfulness of the combination of two immediate word pairs. Therefore, in the main study, the range of word span of collocations has been expanded from one position on the right side of a node (1R) to three words (3R) in the hope of finding collocations with more meaningful combinations. Besides, the pilot study in which the AntConc has been used as the concordance tool has proved that the AntConc is the efficient tool for the study. The complete report of the pilot study is attached in Appendix B.

3.3 Research Part II: Tests of Lexical Collocation Knowledge

This second part of the present study is to examine the fourth year nursing students at SUT on the knowledge of lexical collocations in their field which have gained from the SCNRA in the first part of the study. The results gained from this part

of the study were used to answer Research Question number 3 and 4 of the present study.

RQ 3: How much collocational knowledge do the fourth year nursing students at Suranaree University of Technology (SUT) have based on a test of lexical collocations extracted from the SCNRA?

RQ 4: How much does corpus-based instruction help improve the knowledge of collocations for the fourth year nursing students at SUT?

3.3.1 Participants

Fifty-one fourth year undergraduate nursing students at SUT in trimester 1 of the academic year 2017 were the participants in the test of collocation knowledge. As this group of students was in their final year of study and preparing themselves for their career, it is essential to determine their collocational knowledge in their professional field. This can be a useful indicator for measuring whether the students are sufficiently equipped with knowledge of collocations in their field, the knowledge which should be very useful for both their professional lives and academic advancement.

From the questionnaire asking for their grades received from English courses taken earlier in their previous years of study namely English I to English V, most of them received Bs and higher grades, with some students reported to have Cs. This indicates that this group of students had satisfactory background in English language. The highly competitive in entering the program also is believed to be another factor that make these students to have higher academic performance before entering and during in the program.

3.3.2 Lexical Collocation Test

The test of collocation knowledge of nursing students mainly involves the construction of the test as well as the administration of the test and scoring. There were a pre-test and a post-test. This means that the same test was administered before and after lessons on lexical collocations provided. This is to compare how corpusbased instruction affects the performance of the students. The lesson plan for the lessons provided to the nursing students in details is shown in Appendix C.

3.3.2.1 Procedures in the Construction of Lexical Collocation Test

The procedures involved in this part of the study concern with the test format to be used, the selection of lexical collocations to be tested, the test construction, as well as the pilot of the test.

3.3.2.1.1 Test format

According to Jaén (2007), tests of collocation knowledge can be divided into two types: a test to measure receptive knowledge and to measure productive knowledge. A test of receptive knowledge intends to explore the ability of test takers whether they can select the most appropriate collocates of the nodes given in certain situations. The test formats are those in which alternatives are provided such as in a multiple choice format. For a test of productive knowledge, this type of test is designed to measure whether the test takers are able to use the collocations appropriately in given situations. The test formats are gap filling tasks where test takers are required to fill the missing pairs of the given collocations or translation tasks where test takers have to translate the given collocations from L1 to L2 or vice versa.

The test format to be applied in the present study in order to test collocational knowledge of nursing students at SUT consists of two types of test: a test to measure receptive ability and a test to measure productive ability. For a receptive ability test, a multiple-choice test and a gap-filling with choices provided were used. For a productive ability test, a short sentence writing task was applied since it should very well be able to reflect the ability to produce the language of the test takers.

Since the test comprises the total of 60 test items, the receptive test consists of 30 items of multiple-choice format and 20 items of gap-filling task. The productive test consists 10 items of a short sentence writing task. The number of tasks and test items set are considered adequate amount to allow the test takers in revealing their knowledge to be measured. The time allow for test takers was two hours. The number of test items and the duration allowed were appropriate to keep the test takers to stay focused on the tasks which could give the optimal reliability to the results.

3.3.2.1.2 Item selection

As the lexical collocations gained from the SCNRA comprise over 2,000 pairs, it is not possible to put all of them into the test. Therefore, the collocations to be tested are those pairs with the highest frequency of occurrence. Therefore, the most 200 frequent collocation pairs were randomly put to the test. Also to prevent confusion, only the most 200 frequent pairs of each node (Appendix M) were used as the target collocation pairs regardless of the types of combination.

3.3.2.1.3 Test construction

In this study, after lexical collocations in the SCNRA had been identified and classified, the test of nursing collocations was constructed. The randomly selected 60 collocation pairs were put into three groups according to the test tasks: 30 collocations

for a multiple-choice test, 20 collocations for a gap-filling task, and 10 collocations for a short sentence writing task. This means that for the receptive test, there are a multiple-choice test and a gap-filling task, while the productive test comprises a short sentence writing task.

A multiple choice test consists of 30 discrete sentences with one blank space for the correct pair of the given collocation to be filled in on its right side. Four choices are given for each item.

| Example: health consequences |
|--|
| The health of tobacco products are well established. |
| (a) aftermaths (b) proper <mark>t</mark> ies (c) consequences (d) reactions |
| A gap-filling task consists of 20 discrete items with one blank in each sentence |
| similar to those of a multiple choice test. However, to narrow down the possible |
| collocates to fill the gaps as well as to make it clear for the test to have only one |
| correct answer for each item, the test items are divided into four parts of five test |
| items in each. In each part, the five correct collocates for each item are provided in a |
| box with a choice from "a" to "e". |
| Example: a. stage b. exposure c.index |
| 1. The implementation involves putting resources in place. |
| 2. This study was to explore multipollutant assessments. |
| A short sentence writing task consists of 10 collocation pairs for the test takers |
| to write a meaningful sentence containing the each given pair. |
| For example: public sector, health problems |
| public sector: |
| health problems: |

To make the full use of the SCNRA and to make the test be more specific to nursing context and well as to enrich the test with the authentic language in the real use environment, the sentences to be used to construct the test in order to test each collocation have been taken from the SCNRA. However, simplification may be made to reduce the complexity of the sentences. The test comes with the answer sheet which is separately provided.

3.3.2.1.4 Piloting of the Test

Once the Nursing Collocation Test had been constructed, it was piloted with the fourth year students of nursing during trimester 3 of the academic year 2016 at SUT as these group of students were closest in terms of the target population. This is to assure the validity and reliability as well as practicality of the test. Item analysis was also applied in this process by examining three types of information: difficulty index, discrimination index, and analysis of response options. According to Haladyna, Downing, and Rodriguez (2002), item analysis is "a process of examining class-wide performance on individual test items" (p. 309). The difficulty index indicates the item's difficulty by the number of test takers who answer a particular test item correctly. The discrimination index, meanwhile, is a basic measure of the validity of a test item. It is a measure of an item's ability to discriminate between those who scored high on the total test and those who scored low. The analysis of response options, however, examines the performance of individual distractors on multiple-choice items. By calculating the proportion of test takers who chose each answer option, it would reveal that which distractors are 'working' and appear attractive to test takers who do not know the correct answer, and which distractors are not being chosen. The analysis of response options, therefore, is a great way to fine tune and improve validity and reliability of the test items. The details analysis of the pilot test is shown in Appendix D. The finalized version of the Nursing Collocation Test had been improved and adjusted according to the results found from the pilot test. The complete version of the Nursing Collocation Test which was later used in the pre-test and the post-test is shown in Appendix E.

3.3.2.2 Test Administration and Scoring

The test had been administered with 51 target group of the fourth year nursing students at SUT during the first semester of academic year 2017 in a traditional paper-based manner. The duration allowed for the test was two hours. The test takers were seated in the same room and separated as far as possible to avoid distracting and cheating. The test takers who finished the test before the time given were allowed to leave the room.

In terms of scoring, as each test item has equal score of one point, the total raw score of the test was 60. However, the scores can be viewed as the whole test score and separately according to each of the three parts of the task types. The total score were converted into percentage for the convenience of analysis and clear measurement. The five scale score range was applied by dividing the range equally to form five scale level of performance as shown in Table 3.4 below.

Table 3.4 Score range and performance

| No. | Score range | Performance | |
|-----|-------------|-------------|--|
| 1 | 80 - 100 | Excellent | |
| 2 | 60 - 79 | Good | |
| 3 | 40 - 59 | Fair | |
| 4 | 20 - 39 | Poor | |
| 5 | 0 - 19 | Very poor | |

For the multiple-choice and gap-filling task, as all of the test items contain only one best answer, the inter-raters were not needed. For a sentence writing task, although there are only sentences and with the quite clear holistic marking criteria as shown in Table 3.5 below, the inter-rater was still applied in order to assure the reliability of the results.

Table 3.5 Criteria for marking sentence writing task

| Score | Criteria | |
|-------|---|--|
| 0 | No answer or answer with no meaningful expressions of the given pair. | |
| 0.5 | Answer with some meaningful expressions of the pair, but not completely clear or with grammatical errors. | |
| 1 | Answer with meaningful expressions of the pair with a complete and correct sentence structure. | |

After the pre-test had been administered, lessons on nursing collocation were provided. The post-test of nursing collocations were administered aftermath of the lessons being delivered. The scores of the pre-test and the post-test were compared to examine the test takers' performance in the two tests.

3.3.3 Data Analysis

For the first part of the study, the data analysis was both quantitative and qualitative. This involved classification of the analyzed data in order for answering the first two research questions. For the second part, the results of the test were examined quantitatively using Microsoft Excel and the Descriptive Statistics in the Statistical Package for Social Sciences (SPSS). The scores were analyzed as a whole as well as separately and compared between three test formats. The results of the test are meant to provide a clear answer to the last two research questions of the study.

3.4 Summary of the Chapter

This chapter presented research methodology in the present study. The research design showed that there are two main parts: collocation identification and classification part and the test of collocation knowledge part. The main instruments for the first part of the study are the selected nursing research articles for building a Sample Corpus of Nursing Research Articles (SCNRA), and a corpus analysis tool. The One-Group-Pretest-Posttest was employed in order to investigate nursing lexical collocation knowledge of the nursing students. The data analysis presented how the collected data were analyzed in order for answering the research questions of the study. The following chapter provides the results as well as the discussion of the present study.

CHAPTER 4

RESULTS AND DISCUSSION

The findings of the present study consist of two parts as there have been two phases of study. Findings from part I provide the results of the lexical collocations extracted from the SCNRA. It starts from identifying the keywords from the SCNRA, and then identifying collocates of each keyword to find their collocation pairs. The findings of this part are the answers for research questions 1 and 2. The findings of the research from part II are the pre-test and the post-test results which are the product of the first part's study. This pre-test's results are used as the means for determining collocational knowledge of the nursing students. The post-test's results are analyzed in relation to the pre-test's results to evaluate how much students' performance have improved as the consequence of a corpus-based instruction of the collocations. The discussions concerning the findings are provided on the basis of each research question.

4.1 Research Part I: Identifying Lexical Collocations

This part of the study aims to provide answers to research questions 1 and 2 of the present study.

RQ 1: What are the keywords in the SCNRA based on the frequency of occurrence at ≥ 50 and the keyness value at ≥ 20 ? What is the proportion according to their parts of speech?

The SCNRA – a compilation of 300 research articles from 10 academic journals in the field of nursing comprises 28,054 types and 1,253,992 tokens. Under the set criteria where the frequency of occurrence is at \geq 50 and the keyness value is at \geq 20, there were 855 keywords generated. However, there were some words other than the content words appeared on the keyword list. These words are mainly the function words and pronouns, proper nouns which are not in the focus of the present study, thus they were deleted. Therefore, the number of the keywords found from the SCNRA to be used as "nodes" was 717. The full list of the keywords is shown in Appendix F. Most of the keywords generated have surprisingly high keyness value. The keyword with the highest keyness value is 'nurses' with the keyness value at 34,638.35, while the lowest keyness value is 'understandings' with the keyness value at 197.98. The ten keywords with the highest and lowest keyness values are shown in Table 4.1 below.

Table 4.1 Ten highest and lowest keyness value keywords

| Ten highest keyness value keywords | | | Ten lowest keyness value keywords | | | | |
|------------------------------------|--------------|----------|-----------------------------------|-----|-----------------|---------|-------|
| No. | Keywords | Keyness | Freq. | No. | Keywords | Keyness | Freq. |
| 1 | nurses | 34638.34 | 5115 | 1 | understandings | 197.978 | 50 |
| 2 | care | 25519.82 | 6600 | 2 | recommendations | 198.375 | 146 |
| 3 | health | 25131.96 | 6540 | _3 | category | 198.471 | 171 |
| 4 | study | 21880.57 | 5739 | 4 | suicidal | 198.771 | 55 |
| 5 | participants | 19288.67 | 3058 | 5 | onset | 199.165 | 87 |
| 6 | patients | 19121.00 | 4895 | 6 | clinically | 199.85 | 62 |
| 7 | nursing | 17631.76 | 2991 | 7 | perceive | 200.212 | 90 |
| 8 | patient | 13012.95 | 3019 | 8 | cluster | 200.501 | 91 |
| 9 | mental | 9997.944 | 2245 | 9 | indicates | 200.542 | 141 |
| 10 | nurse | 9905.078 | 1930 | 10 | problematic | 200.658 | 84 |

At this point, the first part of research question 1 has been answered with the finalized number of 717 keywords. However, the answer for the second part of the

research question 1 is to be worked out alongside with the findings of the answers for research question 2, identifying collocations from those keywords.

Following the set criteria, the collocates of each keyword or the node have been identified and recorded according to their combination types on Microsoft Excel Spreadsheet. After the process of identifying collocates of the keywords has been completed, it is possible to categorize the keywords according to their parts of speech. The results showed that the majority of the keywords are the nouns, following with the adjectives, the verbs, and the adverbs respectively. The details of the numbers of each part of speech of the keywords and their percentage are indicated in Table 4.2 below.

Table 4.2 Keywords generated from SCNRA according to their parts of speech

| No. | Parts of speech | Numbers | Percentage |
|-----|-----------------|---------|------------|
| 1 | Noun | 463 | 63.51 |
| 2 | Verb | 98 | 13.44 |
| 3 | Adjective | 157 | 21.54 |
| 4 | Adverb | 11 | 1.51 |
| | Total | 729 | 100 |

Table 4.2 above shows that the keywords generated from the SCNRA are the content words found as keywords of 717 words. It is noticeable that the total number of the keywords has increased from 717 to 729. This is because along the process of identifying collocation pairs, it has been found that some of the keywords functioned more than one part of speech. Keywords such as 'use' and 'need' were found functioning as nouns and verbs as well. The examples are shown in Table 4.3 below.

Table 4.3 Keywords found function more than one part of speech

| Keywords | Function as nouns | Function as verbs |
|----------|--|--------------------------|
| need | (the) need (to) consider, (the) need (to) understand | need assistance |
| use | (the) use (of) technology | use lubricants |

Another reason for the increase number of the keywords is that some compound words were found emerged from the original single keywords. The examples are presented in Table 4.4 below.

Table 4.4 Compound words emerged from single keywords

| Keywords | Become compound words | Example of collocations |
|----------|------------------------------|----------------------------------|
| customer | customer-oriented | customer-oriented behaviors |
| evidence | evidence-based | evidence-based practice |
| family | family-centered | family-centered care |
| high | high-risk | high-risk behaviors |
| hospital | hospital-based | hospital-based oncology |
| nurse | nurse-led | nurse-led clinic |
| parent | patent-child | parent-child relationships |
| risk | risk-assessment | risk-assessment (and) management |

Table 4.4 above provides the evidence to clarify the increased number of the keywords along the process of identifying collocates of the keywords. Due to some of the keywords which are single words combining with other words, new words which are compound words were formed. As a result, the number of the keywords increased.

Among these keywords, the majority of them are the nouns (N = 463), accounted for 63.51 percent. The adjectives (N = 157) come the second accounted for 21.54 percent. The verbs (N = 98) are accounted for 13.44 percent. The smallest number among them is the adverbs (N = 11) accounted for 1.51 percent. The full list of these keywords categorized according to their parts of speech is shown in Appendix I.

The prevalent number of content words such as nouns, adjectives, and verbs in the keywords seems to be common in all corpora. This findings can also be found in the studies conducted by scholars in the field such as Coxhead's (2000) Academic Word List; Mudraya's (2006) one hundred most frequent word families in the Student Engineering Word List; Wang, Liang, and Ge's (2008) Medical Word List; Ward's

(2009) Basic Engineering List generated from his Engineering Corpus; and Yang's (2015) Nursing Academic Word List.

The commonness of the nouns, adjectives and verbs in the corpora also reflects in a number of studies exploring the use of collocation pairs of these keyword types such as the verb-noun collocations in relation to the language proficiency and the knowledge of the verb-noun collocations in EFL learners (Ebrahimi-Bazzaz et al., 2012); the nouns and their collocates (Miščin, 2013); the use of adjective-noun collocations in comparison between learners in the regular and English programs (Suwitchanphan & Phoocharoensil, 2014); and the use of noun-noun collocations in learners' academic writing (Parkinson, 2015).

When comparing the 120 most frequent keywords from the SCNRA with the 120 most frequent academic word families in the Nursing Research Articles Corpus (NRAC) provided by Yang (2015), it is found that 36 words (29.17%) from the SCNRA match with that of the NRAC. These matched keywords are shown in Table 4.5 below.

Table 4.5 Matched keywords in the 120 most frequent of the SCNRA and the NRAC

| approach | assessment | cancer | caregivers | clinical |
|------------|----------------|-------------|--------------|----------------|
| conducted | data 18175 | diagnosis | factors | focus |
| individual | intervention/s | interview/s | items | medical |
| medication | mental | outcomes | participants | perceived |
| physical | positive | previous | process | professional/s |
| research | role | scores | significant | specific |
| status | symptoms | | - | - |

Illustrated above in Table 4.5 are the common keywords found in the two corpora of nursing research articles. It may not seem very high in terms of number and percentage despite the corpus size of the two corpora is relatively similar. The corpus size of the SCNRA is 1,253,992 words, while the NRAC's is 1,006,934 words.

However, the possible cause for not having remarkably high common keywords in the two corpora may stem from the range of nursing journals selected for each corpus. That is the SCNRA comprised 300 research articles from journals in six subject areas, while the NRAC was built from 252 research articles from journals in 21 subject areas which could lead to the difference of words found in the two corpora.

Another factor that may contribute to the difference in the word list found from these two corpora is the way the keywords were listed. The Nursing Academic Word List (NAWL) was generated by means of word families, while the keyword list extracted from the SCNRA in the present study was produced on the basis of individual words. By producing the word list on the basis of word families, it is not possible to determine the frequency of the words when classified according to the part of speech. The different corpus tools used and the criteria applied in extracting the word list may also be the cause of the different results of these two corpora.

With a relatively high match of keywords in these two sample corpora, it implies that these keywords are commonly used in research articles in the field of nursing. Therefore, it should be useful for nursing students as well as nursing practitioners to know these words. This also indicates the pedagogical importance in that the EAP and ESP instructors in the field of nursing could emphasize these words and raise students' awareness of these commonly found words in research articles of their field.

RQ 2: What are the lexical collocations of the keywords in the SCNRA? What is the proportion according to each type of combinations?

Once the keywords from the SCNRA had been identified, the process of identifying their collocates began. The identifying collocation pairs of the keywords

followed the set criteria, namely the word-span of 3 on the right side of the node (3R) and the set frequency of co-occurrence as well as the mutual information value. Under the set criteria, each keyword of four parts of speech can co-occur with different types of words. The summary of the findings is shown in Table 4.6 below.

Table 4.6 Number of Lexical Collocations in SCNRA according to Types of combination

| No. | Combination Types | No. of collocation pairs | (%) |
|-----|--------------------------------|--------------------------|-------|
| 1 | Noun + Noun | 889 | 41.39 |
| 2 | Adjective + Noun | 610 | 28.40 |
| 3 | Noun + Verb | 240 | 11.17 |
| 4 | Verb + Noun | 128 | 5.96 |
| 5 | Noun + Adjective | 84 | 3.91 |
| 6 | Adjective + Adjective | 82 | 3.82 |
| 7 | Verb + Adjective | 34 | 1.58 |
| 8 | Verb + Verb | 24 | 1.12 |
| 9 | Adjective + Ve <mark>rb</mark> | 13 | 0.61 |
| 10 | Adverb + Verb | 12 | 0.56 |
| 11 | Adverb + Adjective | 11 | 0.51 |
| 12 | Verb + Adverb | 10 | 0.47 |
| 13 | Adverb + Noun | | 0.33 |
| 14 | Noun + Adverb | 4 | 0.19 |
| | Total | 2148 | 100 |

Table 4.6 above shows that there are 2,148 collocation pairs generated from the keywords earlier generated. The majority of the collocation pairs is the 'Noun + Noun' combinations with 889 pairs. The number of collocations generated under this combination types are accounted for over 40 percent of all combination types. The 'Adjective + Noun' combination comes second with 610 pairs (28.4%). The 'Noun + Verb' combination comes third with 240 collocation pairs (11.17%). The 'Noun + Adverb' generates the least number of combinations at four pairs (0.19%). Examples of collocation pairs of each combination type are shown in Table 4.7 below.

Table 4.7 Examples of Lexical Collocations extracted from SCNRA

| Nodes | Collocates | Examples |
|--------------|------------|---|
| Noun | Noun | care provider/s, health care, nurses (and) physicians, |
| | | patients (and, and their) families, children (with, |
| | | diagnosed with) cancer |
| | Verb | study (was) conducted, patients (were) admitted, children |
| | | (were, had been) diagnosed, information (was, could be) |
| | | provided |
| | Adjective | patients (with) stable, children (with, diagnosed with) |
| | | chronic, use (of) antipsychotic, risk (of, of developing) |
| | | adverse |
| | Adverb | parents (of, of children) newly, responses (including, |
| | | ranging from) strongly |
| Adjective | Noun | mental (ill, and physical) health, social support, important |
| | | role, clinical (nursing) practice, different types |
| | Adjective | social cognitive, physical (and) psychological, high (and) |
| | Verb | low, medical (and, to a) surgical, positive (and) negative |
| | VEID | important (<i>to</i>) note, significant (<i>difference was</i>) noted, ethical (<i>approval was</i>) obtained |
| T 7 1 | | |
| Verb | Noun | reported feeling, associated (with, with higher) suicide, |
| | | provided (with, with adequate) information, compared |
| | Adjective | (with, with other) women reported (a, to be) moderate, need (to be) aware, |
| | Adjective | associated (with, with a) higher, provide (a) safe, |
| | Verb | use (to) measure, need (to) develop, stated (they, that they) |
| | / 620 | know |
| | Adverb | described above, showed (no) statistically, viewed |
| | 6 | positively |
| Adverb | Verb | significantly associated, specifically designed, positively |
| | Sh | related |
| | Adjective | significantly (associated with) higher, statistically |
| | | significant |
| | Noun | significantly (higher, higher pain) scores, approximately |
| | | (-) minutes |

Altogether, there are 14 combination types of lexical collocations found in the SCNRA under this investigation. This means that there are more combination types than the framework set by the present study adapted from that of Benson et al.'s (2010). Therefore, the findings shown in Table 4.6 above can be categorized into two groups: lexical collocations with combination types according to the set framework

and lexical collocations with combination types not according to the set framework. The former group consists of combination type numbers 1, 2, 3, 4, 11, and 12, while the latter group consists of combination type numbers 5, 6, 7, 8. 9, 10, 13, and 14. The former group comprises 1,888 collocation pairs accounted for 87.9%, the counterpart latter group consists of 260 collocation pairs accounted for 12.1%. These two groups of lexical collocations are shown in Table 4.8 and Table 4.9 below. The lists of these two groups of lexical collocations are shown in Appendix G and Appendix H respectively.

Table 4.8 Lexical Collocations according to the Set Framework

| Combination type No. | Combinations | No. of collocation | (%) |
|----------------------|--------------------|--------------------|-------|
| 1 | Noun + Noun | 889 | 47.09 |
| 2 | Adjective + Noun | 610 | 32.31 |
| 3 | Noun + Verb | 240 | 12.71 |
| 4 | Verb + Noun | 128 | 6.78 |
| 11 | Adverb + Adjective | 11 | 0.58 |
| 12 | Verb + Adverb | 10 | 0.53 |
| | Total | 1888 | 100 |

Table 4.9 Lexical Collocations Not according to the Set Framework

| Combination type No. | Combinations | No. of collocation | (%) |
|----------------------|-----------------------|--------------------|-------|
| 5 | Noun + Adjective | 84 | 32.31 |
| 6 | Adjective + Adjective | 82 | 31.54 |
| 7 | Verb + Adjective | 34 | 13.08 |
| 8 | Verb + Verb | 24 | 9.23 |
| 9 | Adjective + Verb | 13 | 5.00 |
| 10 | Adverb + Verb | 12 | 4.62 |
| 13 | Adverb + Noun | 7 | 2.69 |
| 14 | Noun + Adverb | 4 | 1.54 |
| | Total | 260 | 100 |

When considering the collocations according to the framework of the study which has been adapted from that of Benson et al.'s (2010), it is found that the majority of the collocations gained from the present study are under the set framework. This high in number and percentage of the collocations indicates that the

collocations under the set framework are common combination types. For the collocations which are not according to the set framework, as shown in Table 4.9, there are eight combination types that belong to this group. There are altogether 260 collocation pairs and accounted for 12.1 percent of the total collocations generated from the SCNRA. These collocations constitute combination types which are less commonly found than those in the set framework. These uncommon combination types of collocations have been generated in the present study because of the set criteria for identifying collocations by which the collocates are identified within the range of 3 word-span on the right side (3R) of each node. Since wider word-span leads to more combination types to occur, therefore, with the set word-span in the present study, it allows more combination types to occur. Among these combination types, there are also the less common collocation pairs. These uncommon combination types are also not found and not recommended by scholars and researchers from previous studies in the field. This may be the reason they were excluded in the combination types suggested by Hausmann (1990), Hill (2000), and Benson et al. (2010), except the Adverb + Verb combination that is found suggested by Hill (2000).

When considering the keywords or nodes with their collocates, it is interesting to find out the nodes with the most collocates. The five keywords/nodes of each part of speech thus have been identified with the number of the collocates and parts of speech of the collocates that co-occur with them. The five noun keywords with the most collocates are: *health*, *nursing*, *risk*, *studies*, and *family* respectively. The five adjective keywords with the most collocates are: *physical*, *mental*, *social*, *each*, and *high*. The five verb keywords with the most collocates are: *used*, *diagnosed*,

associated, received, and manage. The five adverb keywords with the collocates are: significantly, positively, negatively, approximately, and strongly. The details of each type of keywords/nodes with the most collocates are presented in Tables 4.10 to 4.13 below.

Table 4.10 Five noun keywords with highest number of collocates

| Keywords (No.) | Nouns | Verbs |
|----------------|--|--|
| health (25) | literacy, professionals, (<i>x</i>) provider/s, promotion, centres, check/s, professions, crisis/es, commission, service/s, insurance, facility/ies, complaints, (<i>x</i> , <i>xx</i>) recommendation, sciences, (<i>x</i> , <i>xx</i>) excellence, workforce, behaviours, (<i>x</i> , <i>xx</i>) care, status, problems, system/s, outcomes, practitioners, issues | - |
| nursing (23) | curricula, home/s, shortage, (x) placement, assistants, profession, pathway, student/s, discipline, educators, (x) environments, practice, workforce, notes, science, teamwork, staff, rounds, leaders, (x) adjustment, documentation, competence, interventions | - |
| risk (16) | (x,xx) ulceration, (x) infertility, (x) stunting, assessment, taking, (xx) defects, (x,xx) reduction, (x) tools, (x,xx) safety, factor/s, (x,xx) harm, (x,xx) developing, (x,xx) bias, management, behaviors, (x,xx) suicide | - |
| studies (15) | ราวากยาลังแกดโมโลยีสุร | investigating, (<i>x</i> , <i>xx</i>) examined, examining, (<i>x</i>) shown, (<i>x</i>) investigated, (<i>x</i> , <i>xx</i>) explored, exploring, focusing, involving, (<i>x</i> , <i>xx</i>) conducted, show, (<i>x</i>) published, (<i>x</i> , <i>xx</i>) evaluated, reporting, (<i>x</i>) focused |
| family (13) | member/s, normalcy, harmony, advocate, (<i>x</i> , <i>xx</i>) friends, caregiver/s, functioning, empowerment, involvement, systems, strengths, dynamics, conversations | - |

Table 4.11 Five adjective keywords with highest number of collocates

| Keywords (No.) | Nouns | Verbs | Adjectives |
|----------------|--|-------|-----------------------|
| physical (22) | activity, fitness, assault, disorder, | - | (x,xx) psychosocial, |
| | performance, restraint, illnesses, | | (x,xx) psychological, |
| | functioning, (x) tests, abuse, function, (x,xx) health, (x,xx) problems, | | (x) emotional |
| | aggression, difficulties, condition/s, | | (x,xx) sexual, |
| | (x,xx) violence | | (x,xx) cognitive |

| mental (21) | (x) triage, (x) crisis/es, (x) commission, (x,xx) health, illness/es, (x) facilities, (x) service/s, (x,xx) workforce, (x) disorder/s, (x) practitioners, (x) practitioners, (x) simulation, (x) consumers, (x) problems, (x) issues, state, (x) settings, (x) professionals, (x) clinicians | - | - |
|-------------|--|--------------|---|
| social (21) | cohesion, gradient, science/s, capital, isolation, network/s, support, norms, worker/s, class, relations, (xx) contexts, media, (x) theory, activities, interaction/s, functioning | - | (x,xx) political, (x,xx) economic, cognitive, (x) cultural |
| each (20) | (x) transcript, (x) item, (x,xx) dimension, (x,xx) site, (x) country, (x,xx) indicator, subscale, (x) component, participant, (x) category, session, domain, (x) theme, (x) member, (x) source, (x) variable, (x) interview, (x,xx) question, year | (x,xx) rated | - |
| high (17) | secure, (<i>x</i> , <i>xx</i>) neuroticism, (<i>x</i>) turnover, (<i>x</i> , <i>xx</i>) extraversion, school, profile, level/s, workload, priority, (<i>x</i> , <i>xx</i>) rate/s, prevalence, (<i>x</i>) demands, degree, (<i>x</i> , <i>xx</i>) burnout, (<i>x</i>) score/s, reliability | - | (x,xx) low |

Table 4.12 Five verb keywords with highest number of collocates

| Keywords (No.) | Nouns | Verbs | Adjectives |
|----------------|---|--|--|
| used (9) | | (x) analyse/ze, (x) compare, (x) collect, (x) assess, (x) measure, (x) examine, (x) describe, (x) evaluate | (x) cross-sectional |
| diagnosed (7) | (x) schizophrenia, (x,xx) cancer, (x,xx) diabetes, (xx) patients, families | คโนโลยีสุร ^ง | (x) oncology, pediatric |
| associated (6) | - | - | (x,xx) decreased, (x,xx) lower, (x,xx) increased, (x,xx) higher, (x,xx) severe, (x,xx) greater |
| received (5) | (x) approval, (x,xx) attention, (x,xx) training, (x,xx) education, (x,xx) treatment | - | - |
| manage (5) | (x,xx) condition, (x) body, (x) child, (x,xx) health, (x,xx) care | - | - |

Table 4.13 Five adverb keywords with highest number of collocates

| Keywords (No.) | Nouns | Verbs | Adjectives |
|-------------------|----------------------------------|---|--|
| significantly (9) | (x,xx) scores | correlated, associated, (<i>x</i> , <i>xx</i>) related, increased | (xx) higher, (xx) lower, (x) likely, different |
| positively (3) | (x,xx) job | associated, related | - |
| negatively (3) | - | correlated, affect, associated | - |
| approximately (3) | (x) min(utes), half, (xx) people | - | - |
| strongly (2) | - | - | disagree/d, agree |

As seen in Tables 4.10 to 4.13 above, it is noticeable that the noun nodes are more likely to co-occur with noun collocates and some possibility to co-occur with verb collocates. The adjective nodes are more common to take noun collocates with a high chance to co-occur with adjective collocates and some chance to co-occur with verb collocates. The verb nodes have higher possibility of co-occurrence with noun and adjective collocates and may co-occur with other verbs. The adverb nodes, although found in small number of collocation pairs, have slightly equal possibility to co-occur with noun, adjective, and verb collocates.

When ranking the lexical collocations according to the frequency of occurrence, it is noticeable that the majority of the 200 most frequent collocations (Appendix J) are in Adjective + Noun and Noun + Noun combinations. Therefore, it should be useful to compile the list of most frequent collocations of these two combination types. The list of 100 most frequent collocations of these two combination types are shown in Appendix K and Appendix L respectively. The prominent number of Adjective + Noun and Noun + Noun combinations is consistent with the study conducted by Biber et al. (2011) where they discover that complex noun phrases are prevalent features found in research articles.

When examining the examples of collocation pairs generated as shown in Tables above particularly in Table 4.7 and Table 4.10, it is noticeable that the majority of the verbs collocates of the noun nodes are those in the passive forms. For example, study (was) conducted, patients (were) admitted, children (were, had been) diagnosed, information (was, could be) provided. This could have pedagogical implication in the way that this linguistic feature should be aware of and pointed out to the learners.

Apart from classification based on types of combination, it is noticeable that the lexical collocations found from the SCNRA can also be categorized into two main groups: nursing specific collocations and general academic collocations. The categorization of these two groups has been arranged in reference to a rating scale for finding technical words designed by Chung and Nation (2003). The examples of these two groups of collocations are shown below in Tables 14.14 and 14.15 respectively.

Table 4.14 Nursing specific collocations

| No. | Nodes | Collocates | No. | Nodes | Collocates |
|-----|------------|----------------------------|-----|---------------|---------------------------------|
| 1 | mental | (ill, and physical) health | 26 | risk | factor/s |
| 2 | health | care | 27 | pediatric | oncology |
| 3 | family | member/s | 28 | nursing | staff |
| 4 | health | service/s | 29 | patients | (and, and their) families |
| 5 | physical | (ill, and mental) health | 30 | parents | (of, and their) children |
| 6 | nursing | home/s | 31 | critical | care |
| 7 | mental | illness/es | 32 | health | problems |
| 8 | care | provider/s | 33 | health | status |
| 9 | service | user/s | 34 | patient | safety |
| 10 | palliative | (and supportive) care | 35 | health | outcomes |
| 11 | family | caregiver/s | 36 | health | literacy |
| 12 | social | support | 37 | acute | (psychiatric, and primary) care |
| 13 | physical | activity | 38 | intensive | (follow-up, support and) care |
| 14 | health | (care) provider/s | 39 | illness | belief/s |
| 15 | quality | (of, of nursing) care | 40 | childhood | cancer |
| 16 | mental | (health) service/s | 41 | chronic | (disease) condition/s |
| 17 | nursing | practice | 42 | psychological | distress |
| 18 | quality | (of) life | 43 | primary | (family) caregiver/s |
| 19 | patient | education | 44 | medication | administration |
| 20 | chronic | (physical, conditions for) | 45 | care | settings |

| 21 | risk | assessment | 46 | health | system/s |
|----|------------|--------------------|----|------------|------------------|
| 22 | registered | nurse/s | 47 | health | issues |
| 23 | nurse | manager/s | 48 | depressive | symptoms |
| 24 | nursing | student/s | 49 | patient | satisfaction |
| 25 | clinical | (nursing) practice | 50 | anxiety | (and) depression |

Table 4.15 General academic collocations

| No. | Nodes | Collocates | No. | Nodes | Collocates |
|-----|---------------|---|-----|---------------|----------------------|
| 1 | present | study | 26 | assessment | tool/s |
| 2 | data | collection | 27 | mean | age |
| 3 | focus | group/s | 28 | qualitative | (research) study/ies |
| 4 | previous | studies | 29 | control | group/s |
| 5 | significant | difference/s | 30 | research | question/s |
| 6 | higher | (mean, and lower) sco <mark>re/s</mark> | 31 | review | board/s |
| 7 | high | level/s | 32 | internal | consistency |
| 8 | mean | score/s | 33 | strongly | agree |
| 9 | sample | size/s | 34 | age | group/s |
| 10 | data | (were) collected | 35 | response | rate/s |
| 11 | age | (of -, ranged between -) years | 36 | age | (and) gender |
| | | # 4 | | | (and socioeconomic) |
| 12 | higher | level/s | 37 | demographic | characteristics |
| 13 | aged | (under -) y <mark>ears</mark> | 38 | everyday | life/ves |
| 14 | statistically | significant | 39 | each | (questionnaire) item |
| 15 | previous | research | 40 | work | environment/s |
| 16 | total | (mean, <mark>h</mark> ealth literacy) score/s | 41 | aim | (of this) study |
| 17 | current | study | 42 | descriptive | statistics |
| 18 | study | (was) conducted | 43 | knowledge | (and) skill/s |
| 19 | research | team | 44 | marital | status |
| 20 | data | analysis | 45 | team | members |
| 21 | informed | consent | 46 | institutional | review |
| 22 | score/s | indicate/ed/ing | 47 | institutional | (review) board/s |
| 23 | systematic | review/s | 48 | content 16 | analysis |
| 24 | inclusion | (and exclusion) criteria | 49 | limitation/s | (of the) study |
| 25 | participate | (in the) study | 50 | participants | (were) asked |

Once the two groups of collocations have been clearly classified, in terms of pedagogical implications, this can greatly benefit both the learners and the teachers. With the clearer target collocations, the teachers should be able to design lessons with a clearer purpose by focusing on each group of collocations separately. Therefore, this should be easier for the learners to notice and recognize the collocations of the two groups.

4.2 Research Part II: Nursing Students' Lexical Collocation Knowledge

After the lexical collocations in the SCNRA had been identified, the Nursing Collocation Test have been constructed and administered with nursing students at SUT. The pre-test results are used as the indicator of the students' knowledge of lexical collocations being tested. The post-test, which was administered following the lexical collocation lessons are used in comparison with the pre-test's results to evaluate how corpus-based instruction affects their performance. The results gained from this part of the study are meant for answering Research Questions 3 and 4 of the present study.

4.2.1 Nursing Students' Collocation Knowledge: Pre-test results

With the pre-test results, the research question number three can be answered.

RQ 3: How much collocational knowledge do the fourth year nursing students at Suranaree University of Technology (SUT) have based on a test of lexical collocations extracted from the SCNRA?

The knowledge of nursing students on collocations found from the SCNRA is determined from the students' performance on the pre-test of the Nursing Collocations Test. The test was administered with the fourth year nursing students (N = 51) at SUT during trimester 1 of the academic year 2017. The summary of the test results in descriptive statistics is shown in Table 4.16 below.

Table 4.16 Pre-test's Results in Descriptive Statistics

Descriptive Statistics

| | N | Minimum | Maximum | Mean | Std. Deviation |
|---------------|----|---------|---------|---------|----------------|
| Prepart1 (30) | 51 | 9.00 | 25.00 | 17.0392 | 3.96465 |
| Prepart2 (20) | 51 | 4.00 | 15.00 | 9.9804 | 3.01656 |
| Prepart3 (10) | 51 | .00 | 8.50 | 3.6373 | 2.18879 |
| PreTotal (60) | 51 | 16.00 | 46.50 | 30.6569 | 7.41383 |

As the results shown in Table 4.16 above, in terms of the total score of 60, the mean score is just over 50 percent of the total score ($\bar{x} = 30.66$). The maximum score is 46.5, while the minimum score is 16. This results in a wide diversity of scores from the mean among the test takers (SD = 7.41). It also shows that the students in this group have different level of knowledge on the nursing collections being tested.

In terms of individual parts, part 1 includes the multiple-choice test of 30 items. The mean score is slightly over 50 percent of the total score of 30 (\bar{x} = 17.04). The maximum score is 25, while the minimum is 9. This indicates that there is less diverse of scores from the mean among the test takers (SD = 3.96). It shows the majority of the students have slightly different level of knowledge on the test, but less than that of the total score's.

For part 2 of the test, the gap-filling of 20 items, the mean score is just under 50 percent of the total score of 20 ($\bar{x} = 9.98$). The maximum score in this part is 15, while the minimum is 4. This leads to a slightly less diversity of scores from the mean of the group (SD = 3.02). It indicates that this group of students still have slightly different level of knowledge on the test, but less than that of the total score's and part 1 score's.

For part 3 of the test, 10 items of a sentence writing task, the mean score is a great deal under 50 percent of the total score of $10 \ (\bar{x} = 3.64)$. The maximum score is 8.5, while the minimum score is 0. However, the score of this part indicates less diversity of scores from the mean of this part (SD = 2.19). This also shows that the majority of the students have similarly low level of knowledge of this part.

In order to clearly demonstrate the students' performance on the pre-test, their scores both the total and each part were converted into percentage. Then the students

were grouped according to their scores in the five score range to give a clear picture on how they had performed on the pre-test as shown in Tables 4.17 to 4.20 below.

Table 4.17 Students' performance on the pre-test for the total score in percentage

| Performance levels | Score ranges | No. of students | Percentage |
|--------------------|--------------|-----------------|------------|
| Excellent | 80 - 100 | 0 | 0 |
| Good | 60 - 79 | 13 | 25.49 |
| Fair | 40 - 59 | 31 | 60.78 |
| Poor | 20 - 39 | 7 | 13.73 |
| Very poor | 0 - 19 | 0 | 0 |
| | Total | 51 | 100 |

From the overall performance of the pre-test on the total score shown on Table 4.17, the performance of the majority of the students is ranked "Fair" (N = 31; 60.78 %). The scores of these students ranged from 40 to 59 on the scale of 100. The performance of the second group is "Good" (N = 13; 25.49 %). Their scores ranged from 60 to 79 on the scale of 100. The performance of another group is "Poor" (N = 7; 13.73 %). Their scores ranged from 20 to 39 on the scale of 100. None of the students' score could reach 80 and higher which is ranked "Excellent", the highest level of performance. Likewise, none of them scored under 20 on the scale of 100 which is "Very poor" and the worst level of performance. This indicates that most of these nursing students have a fair knowledge of nursing collocations. Some of them have good knowledge of nursing collocations, while some of them have poor knowledge of nursing collocations.

Table 4.18 Students' performance on Part 1 of the pre-test in percentage

| Performance levels | Score ranges | No. of students | Percentage |
|--------------------|--------------|-----------------|------------|
| Excellent | 80 - 100 | 2 | 3.92 |
| Good | 60 - 79 | 22 | 43.14 |
| Fair | 40 - 59 | 22 | 43.14 |
| Poor | 20 - 39 | 5 | 9.80 |
| Very poor | 0 - 19 | 0 | 0.00 |
| | Total | 51 | 100.00 |

As seen in Table 4.18, the majority of students' performance on the pre-test for Part 1 in the five-level scale were divided into two groups (N = 22; 43.14% each). The results shows that students' performance equally fell under "Good" and "Fair" levels. The second group (N = 5; 9.8%) fell under "Poor", while the third group (N = 2; 3.92%) fell under "Excellent". There was no student performed under "Excellent" in this part.

Table 4.19 Students' performance on Part 2 of the pre-test in percentage

| Performance levels | Score ranges | No. of students | Percentage |
|--------------------|--------------|-----------------|------------|
| Excellent | 80 - 100 | 0 | 0 |
| Good | 60 - 79 | 17 | 33.33 |
| Fair | 40 - 59 | 24 | 47.06 |
| Poor | 20 - 39 | 10 | 19.61 |
| Very poor | 0 - 19 | 0 | 0 |
| | Total | 51 | 100.00 |

Table 4.19 above shows students' performance in the five levels of performance scale for Part 2 of the pre-test, the majority of them (N = 24; 47.06%) fell under "Fair" level. The second group (N = 17; 33.33%) fell under "Good", while the third group (N = 10; 19.61%) fell under "Poor". There was no student performance ranked under either "Excellent" or "Very poor" level in this part.

Table 4.20 Students' performance on Part 3 of the pre-test in percentage

| Performance levels | Score ranges No | o. of students | Percentage |
|--------------------|-----------------|----------------|------------|
| Excellent | 80 - 100 | 3 | 5.88 |
| Good | 60 - 79 | 8 | 15.69 |
| Fair | 40 - 59 | 11 | 21.57 |
| Poor | 20 - 39 | 18 | 35.29 |
| Very poor | 0 - 19 | 11 | 21.57 |
| | Total | 51 | 100.00 |

As seen in Table 4.20 above, students' performance in the five levels of performance scale for Part 3 of the pre-test reveals that the majority of them (N = 18; 35.29%) fell under "Poor" level. The second group consisted of two different levels

(N = 11; 21.57% each) fell under "Fair" and "Very poor". The third group (N = 8; 15.69%) fell under "Good". There were a few students (N = 3; 5.88%) performed under "Excellent" in this part.

When examining students' performance on each part of the pre-test (as seen in Tables 4.18, 4.19, 4.20), it is noticeable that while there was no student taking part 1 and part 2 of the pre-test performed under the "Very poor" level. However, there were 11 students (21.57 %) in part 3 performed under this level, which is the worst in the five performance scale. This is understandable since writing, even though at a sentence level, which is a productive knowledge as opposed to a receptive knowledge, requires higher knowledge and skill to enable the learners to perform or produce the language (Jaén, 2007; Nation, 2001). Studies conducted by a number of scholars also confirm that EFL/ESL learners performed better in receptive tests than productive ones (Bueraheng & Laohawiriyanon, 2014; Khittikote, 2011; Torabian et al., 2014).

With the performance of the majority of the fourth year nursing students at the "Fair" level indicated by the overall pre-test scores and slightly lower on a sentence writing task, this shows that there is still a great deal of room for improvement. This is consistent with the study conducted by El-Dakhs (2015) that reveals the collocational competence of learners was notably unsatisfactory. A study conducted by Keshavarz and Salimi (2007) also suggests the importance of improving EFL/ESL learners' collocational knowledge to enhance their proficiency level. Ebrahimi-Bazzaz et al. (2012) also endorses that there is a high positive relationship between collocational competence and general language proficiency of learners. With his awareness that Croatian medical students still need to improve their collocational knowledge, Miščin (2013) studied most frequent mistakes students made and compiled a glossary of most

frequent verb collocations. Suwitchanphan and Phoocharoensil (2014) also suggest enhancing Thai learners' collocational competence, especially adjective-noun collocations.

4.2.2 Nursing Students' Collocation Knowledge: Post-test results

Following the administration of the pre-test and a workshop on nursing collocations extracted from the SCNRA, the post-test was administered to measure the effect of corpus-based instruction on students' performance. This also should answer the research questions number four of the present study.

RQ 4: How much does corpus-based instruction help improve the knowledge of collocations for the fourth year nursing students at SUT?

In order to find out how much corpus-based instruction of lexical collocations extracted from the SCNRA could help nursing students improve their performance, the post-test was administered aftermath of the workshop had been provided. The summary of the post-test results in descriptive statistics is shown in Table 4.21 below.

Table 4.21 Post-test's Results in Descriptive Statistics

Descriptive Statistics

| | N | Minimum | Maximum | Mean | Std. Deviation |
|----------------|------|---------|---------|---------|----------------|
| Postpart1 (30) | , 51 | 12.00 | 29.00 | 20.4706 | 4.36968 |
| Postpart2 (20) | 51 | 8.00 | 20.00 | 13.3529 | 3.06479 |
| Postpart3 (10) | 51 | 1.00 | 9.00 | 5.6176 | 1.94059 |
| PostTotal (60) | 51 | 25.50 | 53.50 | 39.4412 | 7.65483 |

As shown in Table 4.21 above, in terms of the post-test total score of 60, the mean score is nearly two third of the total score ($\bar{x} = 39.44$). The maximum score is 53.5, while the minimum score is 25.5. This, however, still results in a wide diversity of scores from the mean among the test takers (SD = 7.65). It also indicates that the students still have different level of knowledge on the nursing collections being tested.

In terms of individual parts, part 1 includes the multiple-choice test of 30 items. The mean score is slightly over two third of the total score of 30 (\bar{x} = 20.47). The maximum score is 29, while the minimum is 12. This indicates that there is less diverse of scores from the mean among the test takers (SD = 4.37). It shows the students have slightly different level of knowledge on the test, but less than that of the total score's.

For part 2 of the test, the gap-filling of 20 items, the mean score is well over 50 percent of the total score of 20 ($\bar{x} = 13.35$). The maximum score in this part is the full score of 20, while the minimum is 8. This leads to a slightly less diversity of scores from the mean of the group (SD = 3.06). It indicates that the students still have slightly different level of knowledge on the test, but less than that of the total score's and part 1 score's.

For part 3 of the test, 10 items of a sentence writing task, the mean score is just over 50 percent of the total score of $10 \ (\bar{x} = 5.62)$. The maximum score is 9, while the minimum score is 1. However, the score of this part indicates the least diversity of scores from the mean (SD = 1.94). This also indicates that the students have fairly similar level of knowledge of this part.

In order to find out how much the students' scores have improved as a result of the corpus-based instruction, the results of the post-test were then compared with those of the pre-test. The list of raw scores of the pre-test and the post-test is shown in Appendix N. In terms of statistical differences between the pre-test and the post-test, a paired samples t-test's results are shown in Table 4.22 below.

Table 4.22 The statistical differences between the Pre-test and the Post-test

Paired Samples Test

| | | Paired Differences | | | | | | | |
|-----------|-------------------------|---|-------------------|-----------------------|-----------|----------|---------|----|------------------------|
| | | 95% Confidence Interval of the Difference | | | | | | | |
| | | Mean | Std. Deviation | Std. Error Mean | Lower | Upper | t | df | Sig. (2- tailed) |
| Pair 1 | Prepart1 - Postpart1 | -3.43137 | 3.28180 | .45954 | -4.35439 | -2.50835 | -7.467 | 50 | .000 |
| Pair 2 | Prepart2 - Postpart2 | -3.37255 | 2.97295 | .41630 | -4.20870 | -2.53639 | -8.101 | 50 | .000 |
| Pair 3 | Prepart3 - Postpart3 | -1.98039 | 1.89990 | .26604 | -2.51475 | -1.44604 | -7.444 | 50 | .000 |
| Pair 4 | PreTotal - PostTotal | -8.78431 | 5.34065 | .74784 | -10.28640 | -7.28223 | -11.746 | 50 | .000 |

In Table 4.22 above, the results of Pair 1 show that there is a significant difference in the mean scores of part 1 of the test between the pre-test and the post-test; t(50) = (-7.47), p = <0.001. Similarly in Pair 2, there is a significant difference in the mean scores of part 2 of the test comparing the pre-test and the post-test; t(50) = (-8.10), p = <0.001. Pair 3 also shows a significant difference in the mean scores of part 3 of the test in comparison between the pre-test and the post-test; t(50) = (-7.44), p = <0.001. There is also a significant difference in the mean scores of the pre-test and the post-test in terms of the total score; t(50) = (-11.75), p = <0.001. This shows that there has been a significant improvement of students' performance on the test.

In order to examine students' performance based on the results of both the pretest and the post-test, the raw scores were converted into the total score of 100. Then the students were grouped according to their scores in the five score range to give a clear picture on how they had performed on both the pre-test and the post-test. For the pre-test, this can indicate the level of their knowledge of nursing collocations prior to the teaching or the providing of the workshop on nursing collocations. For the posttest, this can compare to that of the pre-test in examining whether teaching is necessary or not for collocations.

For the overall test or the total score of 60, the distribution of the students' performance in the five score range from 0 to 100 is shown in Table 4.23 below.

Table 4.23 Students' performance in comparisons between the Pre-test and the Post-test for the total score in percentage

| Total | Pre-test | | | Post-test | Changed | |
|-------------|--------------|----|-------|-----------|---------|--------|
| Performance | Score ranges | N | % | N | % | % |
| Excellent | 80 - 100 | 0 | 0 | 10 | 19.61 | 19.61 |
| Good | 60 - 79 | 13 | 25.49 | 21 | 41.18 | 15.69 |
| Fair | 40 - 59 | 31 | 60.78 | 20 | 39.22 | -21.57 |
| Poor | 20 - 39 | 7 | 13.73 | 0 | 0.00 | -13.73 |
| Very poor | 0 - 19 | 0 | 0 | 0 | 0 | 0.00 |
| | Total | 51 | 100 | 51 | 100 | |

Table 4.23 above shows that there has been an improvement of students' performance. The majority of students (N = 21, 41.18 %) gained satisfactory results under the score range of 60 to 79 at the "Good" level with over 15 percent increase in number. More importantly, there were 10 students (19.61 %) whose results were under the score range of 80 to 100 at the "Excellent" level from which no students attained this level of performance in the pre-test. There were 20 students (39.22 %) whose results were under the score range of 40 to 59 indicating "Fair" level of performance which has decreased over 21 percent comparing to that of the pre-test's. None of the students scored under 40 out of 100 in the post-test.

For part 1 of the test, the multiple-choice test, the distribution of students' performance of both the pre-test and the post-test in the five score range is shown in Table 4.24 below.

Table 4.24 Students' performance in comparisons between the Pre-test and the Post-test for the Part 1 score in percentage

| Part 1 | | Pre-test | | | Post-test | Changed |
|-------------|--------------|----------|-------|----|-----------|---------|
| Performance | Score ranges | N | % | N | % | % |
| Excellent | 80 - 100 | 2 | 3.92 | 13 | 25.49 | 21.57 |
| Good | 60 - 79 | 22 | 43.14 | 23 | 45.10 | 1.96 |
| Fair | 40 - 59 | 22 | 43.14 | 15 | 29.41 | -13.73 |
| Poor | 20 - 39 | 5 | 9.80 | 0 | 0.00 | -9.80 |
| Very poor | 0 - 19 | 0 | 0.00 | 0 | 0.00 | 0.00 |
| | Total | 51 | 100 | 51 | 100 | |

In Part 1 (multiple-choice) of the test, there has been an improvement of students' performance. Firstly, there has been over 21 percent increase of students who scored at "*Excellent*" level from only two students in the pre-test to 13 students in the post-test. Secondly, there has also been an increase in number of students who scored at "Good" level, from 22 to 23 students. Thirdly, the number of students who scored under "Fair" level has decreased over 13 percent from 22 students in the pre-test to 15 in the post-test. Finally, in the post-test, there was no student who scored under "Poor" and "Very poor" levels, while there were five students in the pre-test.

For part 2 of the test, the gap-filling format, the distribution of students' performance of both the pre-test and the post-test in the five score range is shown in Table 4.25 below.

Table 4.25 Students' performance in comparisons between the Pre-test and the Post-test for the Part 2 score in percentage

| Part 2 | | Pre-test | | | Post-test | Changed |
|-------------|--------------|----------|-------|----|-----------|---------|
| Performance | Score ranges | N | % | N | % | % |
| Excellent | 80 - 100 | 0 | 0 | 13 | 25.49 | 25.49 |
| Good | 60 - 79 | 17 | 33.33 | 21 | 41.18 | 7.84 |
| Fair | 40 - 59 | 24 | 47.06 | 17 | 33.33 | -13.73 |
| Poor | 20 - 39 | 10 | 19.61 | 0 | 0.00 | -19.61 |
| Very poor | 0 - 19 | 0 | 0 | 0 | 0 | 0.00 |
| | Total | 51 | 100 | 51 | 100 | |

In this part, there has also been a significant improvement in students' performance. Firstly, there has been over 25 percent increase in the number of students whose score could reach the "Excellent" level, while there was no student achieving such as high level in the pre-test. Secondly, there has been over 7 percent increase in number of students who scored under "Good" level, from 17 students did in the pre-test to 21 in the post-test. Thirdly, the number of students who scored under "Fair" level has decreased over 13 percent, from previously in the pre-test of 24 students to 17 in the post-test. Finally, there was no student scored under either "Poor" or "Very poor" in the post-test, while there were 10 students accounted for nearly 10 percent who did it in the pre-test.

For part 3 of the test, the sentence writing part, the distribution of students' performance of both the pre-test and the post-test in the five score range is shown in Table 4.26 below.

Table 4.26 Students' performance in comparisons between the Pre-test and the Post-test for the Part 3 score in percentage

| Pa | art 3 | | Pre-test | I | Post-test | Changed |
|-------------|--------------|-------|----------|----|-----------|---------|
| Performance | Score ranges | N | % | N | % | % |
| Excellent | 80 - 100 | 3 | 5.88 | 8 | 15.69 | 9.80 |
| Good | 60 - 79 | 8 | 15.69 | 15 | 29.41 | 13.73 |
| Fair | 40 - 59 | 50.11 | 21.57 | 20 | 39.22 | 17.65 |
| Poor | 20 - 39 | 18 | 35.29 | 6 | 11.76 | -23.53 |
| Very poor | 0 - 19 | 11 | 21.57 | 2 | 3.92 | -17.65 |
| | Total | 51 | 100 | 51 | 100 | |

In this part, the post-test results show a positive change in the students' performance as more students achieved higher scores. Firstly, at "*Excellent*" level, there has been nearly 10 percent increase of the number of students whose score could achieve this level, from only three students in the pre-test to eight in the post-test. Secondly, there has also been a positive change at the "*Good*" level with over 13

percent increase in number of students who could attain scores in the post-test to reach this level, from eight to 15 students. Thirdly, there has been over 17 percent increase in number of students who scored at the "Fair" level, from 11 students to 20 students. Fourthly, there has been a significant decrease in number of students who scored under the "Poor" level, over 23 percent from 18 students in the pre-test to only 6 in the post-test. Finally, there has also a considerable decrease in number of students who scored under "Very poor" level, over 17 percent from previously 11 students in the pre-test to only two in the post-test.

Since the nursing students' performance on the pre-test revealed that improvement is needed, it is interesting to find out how a workshop on lexical collocations found from the SCNRA could affect students' performance. With the time restraint coupled with the tight schedule of the students, the workshop introduced students with the 100 most frequent Noun + Noun, Adjective + Noun, 50 most frequent Noun + Verb, Verb + Noun, and 200 most frequent collocations both with repeated and not repeated nodes. The pre-test and post-test were also administered before and after the workshop. After the workshop was provided and the post-test was administered, the test's results revealed the statistically significant improvement on the students' scores on both the total score and on each part of the test as shown on the paired-samples t-test in Table 4.22.

With statistically significant improvement of the students revealed in the comparison of the pre-test's and post-test's results as well as the level of performance compared on the five levels on the scale of 100, teaching of collocations has positive effects on EFL/ESL learners and should be put into wider practice. This is consistent with a number of studies such as studies conducted by Eidian et al. (2013); Khonamri

and Roostaee (2014); Ördem (2013); Pirmoradian and Tabatabaei (2012); Shooshtari and Karami (2013); Szudarski (2012); and Usen and Musigrungsi (2015). It is evident that corpus-based instruction of collocations positively affects students' performance. As collocations are one useful element in achieving natural and native-like level of language performance, corpus-based instruction could be encouraged and put into practice.

Awareness raising, as suggested by Vasiljevic (2014), is an important tool that can facilitate the knowledge of collocations. The notion of noticing recommended by Skehan (1998) is also another productive strategy for language learning in general not particularly for collocations. Corpus-based instruction is one effective instrument to enable learners to notice the features of the language being taught. With guidance through corpus-based instruction with the application of three Is suggested by McEnery et al. (2006) and providing explanation, showing examples, or other means, coupled with learners' cognitive processes, the learners are more likely to be able to notice the features of the language being taught. Once noticed and perceived the targeted language features, those consciously learned features are then kept in memory system to be retrieved for use later when the occasion arises (McCarthy, 1990). This memory system is also called "mental lexicon" (Krashen, 1987; Hulstijn, 2000; Lewis, 2002b; Takač, 2008).

4.3 Summary of the Chapter

This chapter presented the findings of the present study. The findings of the research part I revealed the lexical collocations generated from the Sample Corpus of Nursing Research Articles (SCNRA) as well as the classifications of those

collocations found. It also discussed regarding the keywords extracted which were prevalently the nouns, adjectives, and verbs. The collocates of those keywords, which were used as nodes, were, hence, predominantly with Noun + Noun, Adjective + Noun, and Noun + Verb. These combination types of the collocations were also within the set framework adapted from that of Benson et al.'s (2010). There were some uncommon combination types which were not in accordance with the set framework. This phenomenon occurred as a result of the word-span for the collocates, which was three words from the right side of the node (3R). The wider the word-span allowed for the collocates, the more chances for uncommon combination types were to occur.

The findings of the research part II showed the results of the Nursing Collocation Test in comparison between the pre-test and the post-test. The students' performance had also been examined as to assess the knowledge of the students on nursing collocations found from the study. The discussions of the findings were provided concerning the collocational knowledge of the fourth year nursing students at SUT as revealed by the pre-test. With the level of performance gained, which is in the middle of the scale of five, there was a room for improvement. The students' performance on the post-test administered aftermath of the workshop revealed that their performance had significantly improved. This suggests that corpus-based instruction is beneficial for EFL/ESL learners to improve students' performance and awareness of collocations.

CHAPTER 5

CONCLUSION AND RECOMMENDATIONS

This final chapter provides the conclusion of the present study, the pedagogical implications gained from the present study, and the recommendations for further research.

5.1 Conclusion of the Present Study

As it is crucial for professional nurses to be efficient in English for both their professional advancement and further study, the present study has attempted to facilitate the learning and teaching of ESP in the field of nursing by filling the gap that prevents effective and natural use of English, collocations. Therefore, the present study was conducted (1) to identify and classify keywords found in the Sample Corpus of Nursing Research Articles (SCNRA) published in international journals in the field of nursing; (2) to explore lexical collocations extracted from the SCNRA using keywords found as 'nodes' to find their 'collocates', and to classify collocations produced according to their combinations; (3) to assess collocation knowledge of the fourth year nursing students at SUT based on the collocations identified from the SCNRA; and (4) to provide lessons on nursing collocations and assess the effects of corpus-based instruction. In order to achieve the mentioned objectives, the present study comprised the following research questions.

- 1) What are the keywords in the SCNRA based on the frequency of occurrence at ≥ 50 and the keyness value at ≥ 20 ? What is the proportion according to their parts of speech?
- 2) What are the lexical collocations of those keywords in the SCNRA? What is the proportion according to each type of combinations?
- 3) How much collocational knowledge do the fourth year nursing students at Suranaree University of Technology (SUT) have based on a test of collocations extracted from the SCNRA?
- 4) How much does corpus-based instruction help improve the knowledge of collocations for the fourth year nursing students at SUT?

The study consisted of two main parts: 1) identification and classification of lexical collocations from the SCNRA, and 2) collocational knowledge of fourth year nursing students at SUT. The present study started with the research part 1 by compiling 300 research articles from 10 selected academic journals in the field of nursing accessible online via SUT's Library Resources. The SCNRA which comprised over 1.25 million words generated 717 keywords under the set criteria. Among these keywords found, the majority were the nouns (N = 463; 63.51%), followed by the adjectives (N = 157; 21.54%), the verbs (N = 98; 13.44%) and the adverbs (N = 11; 1.51%). These keywords then were used as the "nodes" to find their collocates with 3 word-span on the right side (3R). 2,148 pairs of lexical collocations were identified with 14 combination types. The majority of the collocation pairs found were Noun + Noun (N = 889; 41.39%), followed by Adjective + Noun (N = 610; 28.4%), and Noun + Verb (N = 240; 11.17%). Among these 14 combination

types, the majority of them were in accordance with the set framework of six combination types adapted from Benson et al. (2010).

Once the lexical collocations had been identified and classified, the research part 2 was able to be commenced. In order to assess collocational knowledge of the fourth year nursing students at SUT, a Nursing Collocation Test was constructed. A list of 200 most frequent collocations identified from the SCNRA was used to construct the test. To avoid confusion, these 200 pairs of collocations were chosen from those of the highest frequency of each node. These 200 pairs of lexical collocations were then randomly selected for 60 test items. These 60 test items consisted of three parts: 30 items of a multiple-choice test; 20 items of a gap-filling test; and 10 items of a sentence writing task. The tryout of the test was carried out with 38 fourth year nursing students during trimester 3 of the academic year 2016. The tryout test was examined for the Difficulty Index, Discrimination Index, and Reliability Index. The improvement of the test had been made accordingly to the analysis.

The Nursing Collocation Test was administered with 51 fourth year nursing students at SUT during trimester 1 of the academic year 2017 before and after a 12 hour-workshop on nursing collocations organized for them. The pre-test's mean of the total score was 30.66 with the standard deviation of 7.41 ($\bar{x} = 30.66$; SD = 7.41). This revealed that the overall knowledge of collocations of the majority of the students was at a "Fair" level. The post-test's mean of the total score was 39.44 with the standard deviation of 7.65 ($\bar{x} = 39.44$; SD = 7.65). To evaluate the effects of corpus-based instruction on the students' performance, the results of the pre-test and the post-test were compared using the paired samples t-test. The results showed that there were

statistically significant improvements of the students' performance in the total score (t(50) = (-11.75), p = <0.001) as well as in each of the three parts of the test: part 1 (t(50) = (-7.47), p = <0.001); part 2 (t(50) = (-8.10), p = <0.001); and part 3 (t(50) = (-7.44), p = <0.001). In terms of the students' performance, the majority of the students' scores increased and put them one level higher in all parts from "Fair" to "Good", except for part 3, a sentence writing task, the level of performance was improved from "Poor" to "Fair".

The present study has added more resources to the ESP as well as EAP and EFL/ESL teaching and learning by means of producing both keyword list and lexical collocations. It has opened up and widened the road to success for nursing students and nursing professionals who seek means for effective and natural communication in their profession. The present study also has specifically filled the gap or at least narrowed down the gap in terms of collocations in the field of nursing both locally in Thailand and beyond in raising the awareness of collocations through the collocation test and corpus-based instruction.

5.2 Pedagogical Implications from the Present Study

As the present study has examined lexical collocations in the field of nursing through the building of a sample corpus of nursing research articles and investigated the knowledge of the fourth year nursing students at SUT, there are a number of pedagogical implications emerged from the present study. These implications are as follows:

Firstly, applying a corpus tool or concordance tool in extracting collocations from teaching and learning materials such as textbooks and related documents can be

beneficial in ESP such as the field of nursing as presented in the present study, as well as in EAP and EFL/ESL teaching and learning in general. By extracting collocations from materials used in each course of particular field of study and classifying as well as making the list of the collocations, this should make it clearer and easier for both the instructors and the learners to notice those collocations. This also is a great way to raise awareness of collocations among the EFL/ESL learners.

Secondly, corpus-based instruction of collocations is beneficial in helping EFL/ESL learners to be aware of the target collocations. With guidance from teachers, coupled with proper teaching and learning materials and exercises, the learners can gain a clear idea about collocations, their usefulness, and how the pairs occur in real contexts.

Thirdly, incorporating a corpus-based teaching and learning of collocations can also be beneficial in the teaching and learning of English from general EFL/ESL to EAP and ESP. By showing the concordance lines from a corpus built from materials used in the course such as textbooks and related documents, the learners can see the target collocations in the real use and authentic contexts (Gaskell & Cobb, 2004; Yoon & Hirvela, 2004; Kırkgöz, 2006; Lee & Swales, 2006; Wang et al., 2015). This should encourage the correct and natural use of the collocations.

Finally, testing students' collocational knowledge can be a helpful means in examining how much students know the target collocations. This is useful information for teachers to introduce students to those collocations, as well as how much attention is needed for particular pairs of collocations. The post-test or the test after collocations being taught also helps the teachers in assessing how much the students'

performance have improved after being taught, as well as how effective the lessons and the teaching methods are when being delivered by the teachers.

5.3 Recommendations for Further Research

Firstly, as the present study has focused solely on lexical collocations, it is recommended that a further research could be conducted by extending the focus to grammatical collocations. This could be done either by only focusing on the grammatical collocations or together with the lexical collocations so that the comparisons between the two could be made.

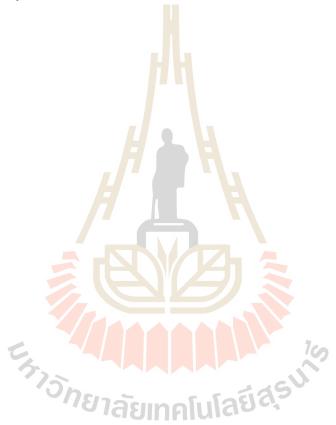

Secondly, as the present study has focused on the field of nursing, further research could be conducted by focusing on a variety of other fields which have not been conducted. This is to make collocations in other academic fields be more accessible and to facilitate the teaching and learning of collocations in those fields.

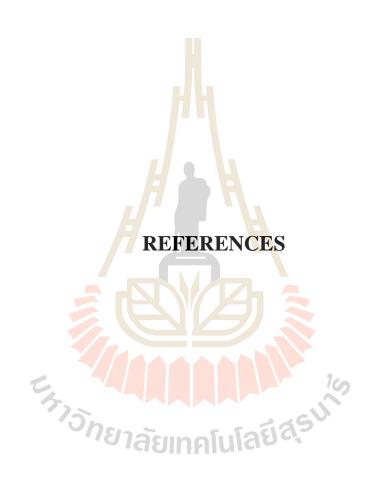

Thirdly, as research articles from academic journals have been used in the present study, further research could be conducted using other types of materials such as textbooks, magazines, news' columns, and the like. This is to make collocations available from various genres.

Finally, as the present study applied the whole IMRD parts of the research articles, further research could be conducted by separating the four different parts and comparing the results gained from those different parts of the research articles. This is to examine the similarities and differences of collocations of the same genre for their different parts.

5.4 Summary of the Chapter

This chapter has presented the conclusion of the present study. In the first part, it summarized the whole research study from the beginning to the end. In the second part, it suggested the pedagogical implications gained from the present study. Finally, it recommended the possibilities for further research which could be extended from the present study.

Lexical Collocations in a Sample Corpus of Nursing Research

Articles (SCNRA): Pilot Study

I. Objectives

The objectives of this pilot study are:

- 1. To examine the plausibility of the research project which intends to explore lexical collocations found in a Sample Corpus of Nursing Research Articles (SCNRA).
- 2. To explore whether any adjustments are necessary in order to conduct the main study successfully.

II. Data Collection Procedures

The pilot study was conducted with a sample corpus of nursing journal articles compiled from 10 journals in the field of nursing intended for the main study. The important procedures in this pilot study involve the selection and compilation of the journal articles.

1. The selection of the journal articles

In the main study, it intends to investigate lexical collocations found in 10 journals in the field of nursing accessible online via Suranaree University of Technology's (SUT) Library Resources in which the 30 latest journal articles of each selected journal will be used. These journals are as follows:

- 1) Journal of Epidemiology & Community
- 2) Health International Journal of Mental Health Nursing
- 3) Journal of Nursing Management
- 4) Nursing Inquiry
- 5) Journal of Family Nursing
- 6) Clinical Nursing Research
- 7) Journal of Clinical Nursing
- 8) Journal of Pediatric Oncology

- 9) Nursing Journal of Psychiatric and Mental Health
- 10) Nursing International Journal of Nursing Practice

For this pilot study, five research articles from each of the journals listed above were selected to comprise 50 journal articles. With the articles of at least 3,000 word length, the size of the sample corpus should be at least 150,000 words. This corpus size should give sufficient richness of the sample corpus as well as sufficient keywords and their collocates to be examined.

Criteria for selecting journal articles

- 1) The selected articles were those in the IMRD format since it is commonly used in quantitative and experiment-based research and found used in the journal in the field of nursing.
 - 2) The selected articles were those with the length not less than 3,000 words.
- 3) As the main study intends to conduct with the 30 latest journal articles from each of the journals, the five articles selected from each journal for this pilot study were those published earlier than the 30 latest articles.

2. Procedures in compiling the articles

- 1) Once the articles that met the criteria had been identified, the IMRD parts of each article were saved into text files. This means that the abstract, figures, tables, graphs, references and footnotes were left out. The name of each file was given for the purpose of identification and management.
- 2) Once the selected articles had been compiled, they were uploaded onto the corpus analysis tool, AntConc version 3.4.4, for the analysis. The AntConc is used as to try out its appropriateness to be used as the analysis tool in the main study.

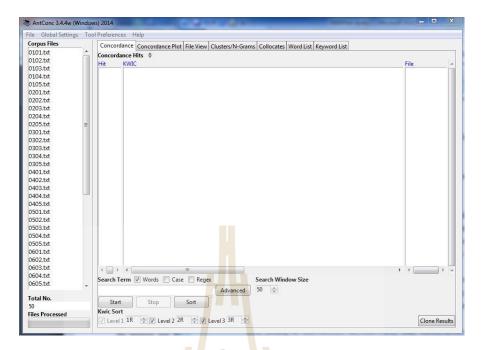

III. Data Analysis Procedures

Data analysis at this stage involves two main steps: the identification of keyword and the identification of the collocations in the sample corpus.

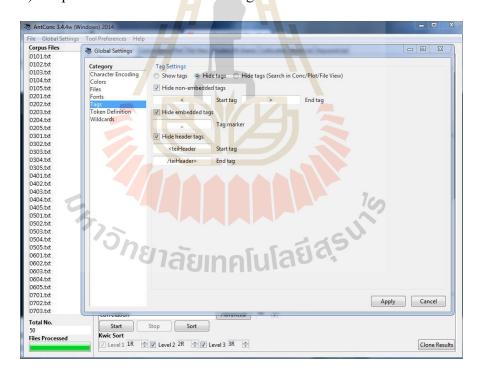

1. Procedures in identifying keywords

Once the selected files were complied, the following procedures were applied to identify the keywords of the corpus being studied.

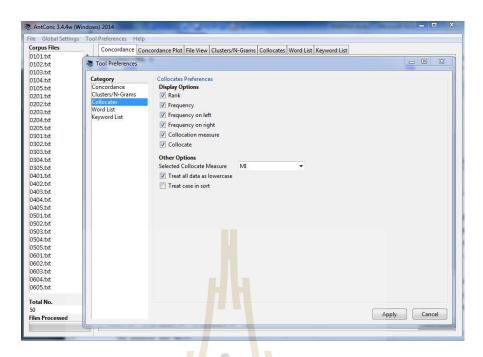

1) Upload the text files to be studied onto the analysis tool, the AntConc. The latest version 3.4.4 was used. For this pilot study, 50 text files compiled from 10 journals were uploaded.

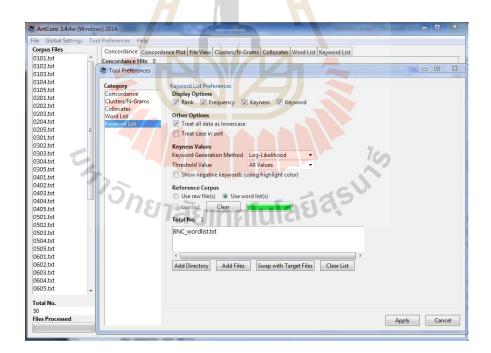

2) Set preferences in 'Global Settings'.

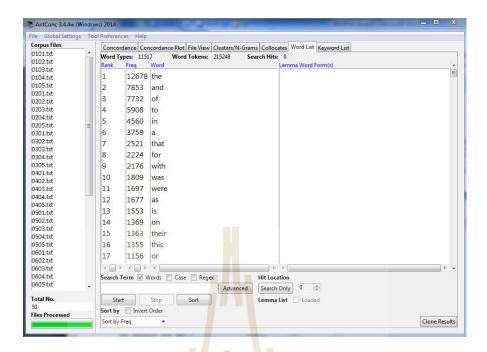

3) Set preferences in 'Tool Preferences'. At this stage, under 'Collocates', MI value is selected as a statistic measure for the association strength of a collocational pair.

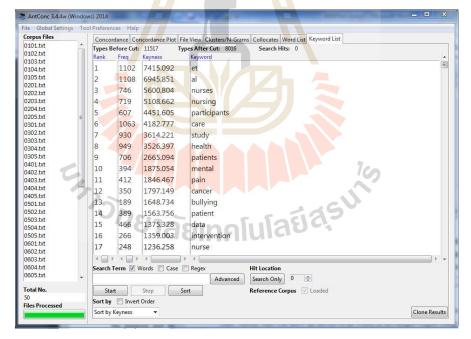

Also, at this stage, under 'Keyword List', Reference Corpus is uploaded. For this study, the British National Corpus is used as the reference corpus.

4) Once all the preferences were set, the analysis started. By clicking on the 'Word List' tab followed by clicking on 'Start' button, the results showed the numbers of types and token of the corpus being studied. The words in the corpus were also displayed according to their number of appearance.

5) By clicking on a 'Keyword List' tab, set 'sort by keyness', and follow by the 'Start' button, the list of keywords of the corpus being studied revealed.

As seen on the picture above, not every word on the list is acceptable as keywords. For example, the first two words on the list being 'et' and 'al'. These two words were not acceptable as keywords. Therefore, the researcher had to look through the list and manually made the list of 500 keywords to be ready of the following stage

of the study, identifying collocations. The list of the first 500 keywords according to the keyness is shown in the Appendix BA.

2. Procedures in identifying collocations

Once the list of keywords were ready, as they were used as the 'nodes', the process of identifying their pairs or 'collocates' started as follows:

- 1) Under the 'Keyword List' tab, click on a word acceptable to be the node, for example, the word 'Nurses'. The program displayed under the 'Concordance' tab to show the concordance line the word 'Nurses' appeared in the entire corpus with the number of occurrence.
 - 2) To find the collocates, click on the 'Collocates' tab.

Before clicking on 'Start' button, three preferences were set as follows:

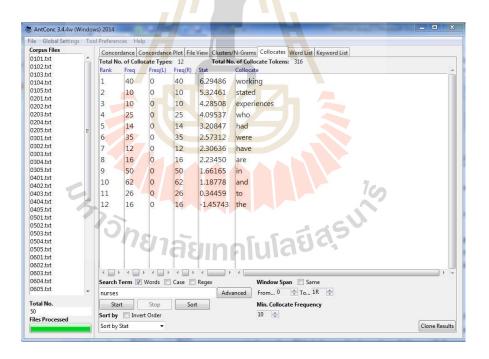

Under 'Window Span', set as 'From 0 to 1R' as the study intends to investigate the two word collocates on the immediate right side of the nodes.

Under 'Sort by', select 'Sort by Stat' as the study give more important to the MI score than the frequency of occurrence.

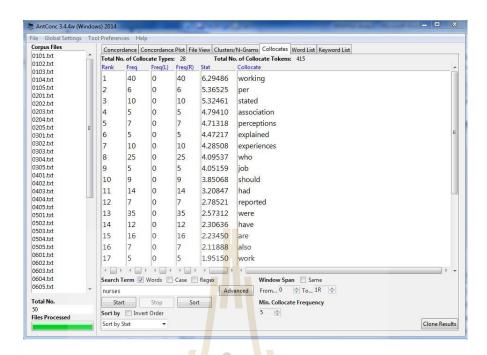

Under 'Min. Collocate Frequency', set as '10' as the study set the number of the co-occurrence of the pairs at least 10. However, the number of occurrence can be reduced in case of the number of co-occurrence does not meet the criteria. In that case, the intention will be paid on only the MI value of the pair.

Once the preferences were set accordingly, click on 'Start' button.

3) After clicking on 'Start' button, the collocates of the node 'Nurses' revealed. However, as the criteria set for the study that the collocates have to have the MI value at least 3 with the frequency of occurrence at least 10, not all of the words on the list were acceptable collocates. Even those words that meet the criteria are not always eligible to be acceptable pair. In the case of the node 'Nurses', for its collocates shown in the picture below, although the collocate 'working' being the highest ranking in terms of the MI score with the frequency of co-occurrence of 40, they are not considered acceptable pair of collocation. The acceptable collocational pair for the node 'Nurses' in this studied corpus are 'stated' as a Noun+Verb collocation. The collocate 'experiences' was not acceptable collocation as when click on the word to show in the concordance lines it revealed that the pair was in 'nurses' experiences' which with an apostrophe in between them to show possession. Therefore, this pair was not an acceptable pair of collocation in this study.

When reduce the number under 'Min. Collocate Frequency' from 10 to 5, some new collocates appeared on the list. The acceptable collocate on the new list was 'association' as a Noun+Noun combination. However, the collocate 'perceptions' which looked promising was not acceptable as the pair was with an apostrophe in the middle as the case of the collocate 'experiences'.

- 4) The process is repeated for other words to find their collocates.
- 5) The collocations generated from the 500 keywords or nodes found were grouped together according to the combinations. The combination patterns of the lexical collocations in the study are adapted from that of Benson et al. (2010). That is from the original seven combinations, the present study has adapted to six combinations. This is to create collocations of two immediate word pair on the right side of the nodes which closely related to vocabulary or the extension of the normal single unit vocabulary. The comparison between the combinations given by Benson et al. (2010) and the adapted combinations for the present study is shown in Table 1 below.

Table 1 Lexical Collocation: Benson et al. (2010) and Adapted in Comparison

| Types | Combinations by Benson et al. (2010) | Types | Combinations adapted |
|-------|--------------------------------------|-------|----------------------|
| L1 | Verb + Noun | | |
| L2 | Verb + Noun | L1 | Verb + Noun |
| L3 | Adjective + Noun | L2 | Adjective + Noun |
| L4 | Noun + Verb | L3 | Noun + Verb |
| L5 | Noun + of Noun | L4 | Noun + Noun |
| L6 | Adverb + Adjective | L5 | Adverb + Adjective |
| L7 | Verb + Adverb | L6 | Verb + Adverb |

IV. Results

The sample corpus of 50 research articles from the 10 journals in the field of nursing comprises 11,517 types and 225,248 tokens. 500 keywords were selected according to the ranking of their keyness value and frequency of occurrence for further analysis. The list of the keywords is presented in Appendix BA. When classified into categories according to the part of speech, the 500 selected keywords consist of 348 nouns (65.5%), 118 adjectives (22.2%), 58 verbs (10.9%), and 7 adverbs (1.32%) as shown in Table 3.1 below.

Table 3.1 Numbers and percentage of 500 keywords according to parts of speech

| No. | Parts of speech | Number | Percent |
|-----|-----------------|--------|---------|
| 1 | Nouns | 348 | 65.5 |
| 2 | Adjectives | 118 | 22.2 |
| 3 | Verbs | 56 | 10.9 |
| 4 | Adverbs | 7 | 1.32 |
| | Total | 531 | 100 |

These keywords were then used as 'nodes' for the next step of the study which was to find out the collocates of each keyword. In the present pilot study, as the lexical approach is emphasized, lexical collocations of the nodes will be explored. From the keywords according to their parts of speech presented in Table 3.1 above, the collocations found from the sample corpus can be divided into three groups as follows: 1) lexical collocations according to the set framework; 2) collocations not according to the set framework; and 3) keywords/nodes with no collocates. The numbers and percentage of each group are presented in Table 3.2 below.

Table 3.2 Numbers and percentage of collocations generated from 500 keywords

| No. | Parts of speech | Number | Percent |
|-----|---|--------|---------|
| 1 | Lexical collocations according to set framework | 281 | 52.92 |
| 2 | Collocations not according to set framework | 174 | 32.77 |
| 3 | Keywords/nodes with no collocates | 76 | 14.31 |
| | Total | 531 | 100 |

For the first group, which presents collocations the present study intends to investigate, it reveals the lexical collocations of 281 keywords or nodes that account for 52.92 percent. The numbers and percentage according to the combination types are shown in Table 3.3 below. The complete list of these lexical collocations is presented in Appendix BB.

Table 3.3 Number and percentage of lexical collocations according to types of combination

| No. | Types of combination | Number | Percent |
|-----|---------------------------------------|--------|---------|
| 1 | L1: Verb + Noun | 10 | 3.56 |
| 2 | L2: Adjective + Noun | 115 | 40.93 |
| 3 | L3: Noun + Verb | 26 | 9.25 |
| 4 | L4: Noun + Noun | 124 | 44.13 |
| 5 | L5: Adverb + Adjecti <mark>v</mark> e | 3 | 1.07 |
| 6 | L6: Verb + Adverb | 3 | 1.07 |
| | Total | 281 | 100 |

The second group, collocations which are not according to the set framework, comprises 174 keywords or nodes with their collocates other than lexical collocations. The majority of these collocations can be categorized as grammatical collocations. Table 3.4 below gives the numbers and percentage of the results in this group. The complete list of collocations in this group is presented in Appendix BC.

Table 3.4 Numbers and percentage of collocations: other types of combination

| No. | Types of combination | Number | Percent |
|-----|---|--------|---------|
| 1 | O1: Noun + Others (e.g. $of+N$, $prep+N$, $Vbe+V3$) | 127 | 72.99 |
| 2 | O2: Verb + Others (e.g. <i>prep.</i> + <i>N</i> , <i>that</i> + <i>clause</i>) | 41 | 23.56 |
| 3 | O3: Adjective + Others (e.g. <i>prep.</i> + <i>N phrase</i>) | 3 | 1.72 |
| 4 | O4: Adverb + Others (e.g. <i>V, prep.</i> + <i>clause</i>) | 3 | 1.72 |
| | Total | 174 | 100 |

The last group, keywords or nodes with no collocates, comprises 76 keywords that account for 14.31 percent. The majority of them are the nouns. Table 3.5 below shows the numbers and percentage of each type of keywords with no collocates. The complete list of this group of keywords is provided in Appendix BD.

Table 3.5 Numbers and percentage of keywords with no collocates

| No. | Keywords with no collocates | Number | Percent | |
|-----|-----------------------------|--------|---------|--|
| 1 | Nouns | 72 | 93.42 | |

| 2 | Verbs | | 4 | 5.26 |
|---|---------|-------|----|------|
| 3 | Adverbs | | 1 | 1.32 |
| | | Total | 76 | 100 |

V. Discussion

From the findings gained from the pilot study, it is found that from the 500 keywords generated, the majority of them, 65.5 percent, being the nouns. The adjectives come the second place at over 22 percent. The verbs come third at over 10 percent and the adverbs are the least in number, just over 1 percent. Having assigned these keywords as nodes to explore their collocates with one span on the right side to form immediate two word collocations, the results are reported earlier above. It is interesting that these keywords yield the results that can be divided into three groups as shown in Table 3.2 above. Among these three groups, the majority being lexical collocations with the combinations according the set framework of over 52 percent, generated from 281 keywords. The rest of the keywords give the results not according to the set framework that can be divided into two groups: grammatical collocations and no collocations.

As the main focus of the study is on the group of lexical collocations to further apply in the assessment of SUT nursing students' knowledge of lexical collocations, the proportion of the group with over 52 percent and 281 in number is considered large enough to meet the purpose. Although the results reveal that there are combinations of words both within the framework and outside of the framework, all of the combinations are worth investigation as they actually occur in the real use of the language. Thus, despite the focus of the study is on the lexical collocations of the set framework, knowing other possible collocates or no collocates is still useful in effective communication and use of the language as well as the EFL/ESL learning and teaching. With the larger sample size in the main study, it is believed that the results could be slightly different and more statistically significant.

VI. Conclusion

As the objectives of this pilot study are to examine the plausibility of the research project as well as to explore whether any adjustments are necessary in order to successfully conduct the main study, the results of the pilot study assure that this research project is plausible with no adjustment needed.

APPENDIX B.1 List of 500 Keywords generated from the sample corpus

| Rank | Freq | Keyness | Keywords | Rank | Freq | Keyness | Keywords |
|------|------|----------|-------------------|------|------|----------|-----------------|
| 1 | 746 | 5600.804 | nurses | 250 | 18 | 146.602 | oncology |

Appendix C

Nursing Collocations' Lesson Plan

Tentative schedule

| No. | Contents | Hours |
|-----|--|-------|
| 1 | - Introduction to the project and the workshop program | 1 |
| | - Pre-test on Collocations in Nu <mark>rsi</mark> ng Research Articles | 2 |
| 2 | Noun + Noun collocations; Adjective + Noun collocations | 2 |
| 3 | Noun + Verb and Verb + Noun collocations | 1 |
| 4 | 200 most frequent collocations | 1.5 |
| 5 | 200 most frequent collocations according to individual nodes | 1.5 |
| 6 | Summarizing the whole lesson | 1 |
| 7 | Post-test | 2 |
| | Total | 12 |

Due to a tight schedule of the nursing students, the collocation tests and the workshop were arranged to fit in a two-day schedule given upon the availability of the students.

From the tentative schedule above the lesson plan can be arranged as follows:

| No. | Topics | Duration (hour) |
|-----|---|------------------------|
| 1 | Noun + Noun collocations | 1 |
| 2 | Adjective + Noun collocations | 1 |
| 3 | Noun + Verb collocations | 0.5 |
| 4 | Verb + Noun collocations | 0.5 |
| 5 | 200 most frequent collocations | 1.5 |
| 6 | 200 most frequent collocations according to each node | 1.5 |

The objectives:

There are two main objectives for the lesson. One is to introduce students to lexical collocations in the field of nursing. The other is to administer the pre-test and the post-test with the target students. This is to investigate students' knowledge of collocations from the results of the pre-test and to examine the effect of corpus-based instruction of collocations on the knowledge of the students from the results of the post-test.

Teaching methods:

Since the present study is a corpus-based study with the emphasis on lexical approach particularly focusing on collocations found from the studied sample corpus, the teaching method to be applied in the workshop is a corpus-based instruction applying "Three Is: Illustration, Interaction, and Induction as suggested by McEnery et al. (2006). By showing students examples of how words are used and what words they collocate with in the real contexts as shown in concordance lines is beneficial to the EFL/ESL learners (Kozlowski & Seymour, 2003).

Corpora are useful tools for engaging learners in the interpretive process to create models of their own (Leech, 1986). Corpus-based teaching and learning can capture reality and are able to provide valid models for learners as they represent authentic language (Gavioli & Aston, 2001). Corpus tools show students the frequency of particular features of the language (Coxhead, 2010). A corpus reveals register variation of a language and a complex relationship between lexicon and grammar. It also allows learners to investigate the frequency of formulaic lexical bundles in any register (Samburskiy, 2014). A number of studies showed the advantages of demonstrating words in concordance lines over only traditional gapfilling or matching exercises (Cobb, 1997, 1999; Horst, Cobb, & Nicolae, 2005; Pickard, 1994; Stevens, 1991; Thurstun & Candlin, 1998). Concordance lines also enable learners to see variation of linguistic structures, promoting a process of synthesis and analysis of information on their part, which is the key to the acquisition process (Aston, 1995). Additionally, engaging students in corpus-based activities promotes noticing or consciousness-raising (Conrad, 2005; Thurstun & Candlin, 1998).

Materials and instruments:

The main materials and instruments for the workshop on lexical collocations extracted from the SCNRA are a concordance program and online exercises as well as handouts of each collocation pair.

The concordance program used is the AntConc version 3.4.4 loaded with the Sample Corpus of Nursing Research Articles (SCNRA). This enables the researcher to show the concordance lines of particular collocation pairs to the students.

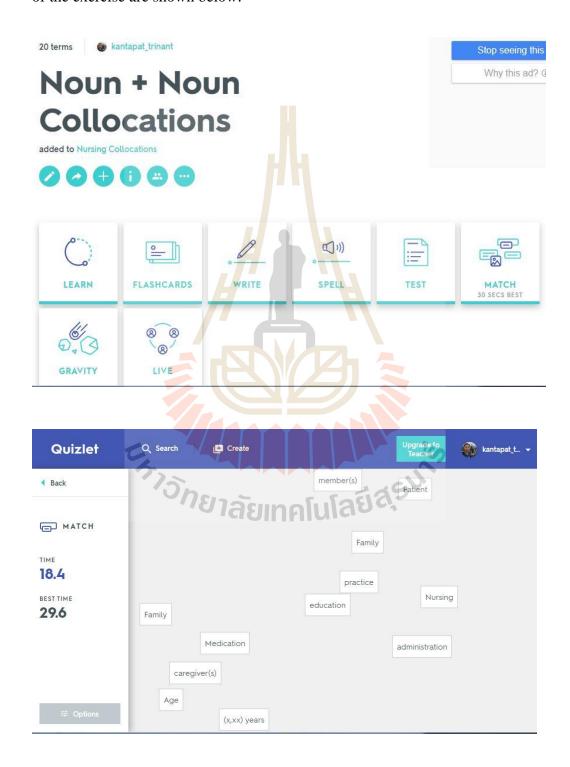

The online exercises used are generated through facilities provided by the website **Quizlet.com**. With this website, the researcher can generate matching exercises of collocation pairs and use them as a warmer task to draw attention of the students for each lesson. Handouts of collocations of each topic are also provided.

The lesson plan:

After the introduction and the pre-test, the lesson begins. As the lesson is on collocations of different types of combination, the lesson is carried out under the similar pattern and procedures as follows:

Introduction: (Time: 5 - 10 minutes)

For each topic, the lesson starts with a matching exercise generated from the online resource website, **Quizlet.com**. This exercise should draw the attention of the students to the lesson as well as give them some ideas of what collocations are. The interfaces of the exercise are shown below.

This matching exercise is a Noun + Noun collocations exercise. When a word is dragged onto its pair, the pair will disappear. This exercise should take less than ten minutes.

The lesson: (Time: depends on the time allowed for each topic)

After the matching exercise, the lesson begins. Handouts of the collocation lists according to the topics will be distributed for each lesson to show the collocations pairs of each type of combination. Then, the concordance lines for each collocation pair are shown on the corpus tool, the AntConc. By showing the concordance lines, the students get the opportunity to see how the collocation pairs appear in the context of the real language use. The explanations and discussion on the meaning and the context of the collocation pairs are carried out in order for the students to understand the context where the collocation pairs are used. The interface of the concordance lines of the pair 'health + care' is shown below as the example.

The figure above shows how the collocation pair appears in the concordance lines.

Then the full sentences of the collocation pairs are shown in order to discuss their contexts and meaning.

Alongside the decrease in the overall level of social care provided, the literature has highlighted the increasing participation of the private sector in the 'mix' of long-term care and the concomitant decrease in the level of care provided by local authorities.8 Since the 1990s, different types of long-term care have developed, responding to the policy aim of successive governments since the 1980s to provide greater choice to users of long-term care. Different long-term care providers typically cater for different groups of the older population depending on individuals' health and social care needs, as well as key demographic and socioeconomic characteristics, such as their partnership status and ability to purchase privately provided care.9,10 Against this context, sheltered accommodation has developed as a key alternative within the mixed

Participants were not unique in their lack of primary health care. In general, presentation to primary health-care services by young people is low because they do not understand them and associate them with discomfort and minimal confidentiality (Jones & Bradley 2007; NSW Centre for the Advancement of Adolescent Health 2008). It is common for young adults with

Tackling inequalities in physical health and life expectancy demands improved access and quality of physical health care for people with mental illness. There is often inconsistent and low access to quality physical health services such as screening, effective referral processes, continuity of care and participation in health-behaviour programmes (Connolly et al. 2015; Hyland et al. 2003; Nasrallah et al. 2006). In recent years, the debate on how to address physical health service gaps has become more prominent (De Hert et al. 2011; Ehrlich et al. 2015; Lawrence & Kisely 2010; Richardson et al. 2005). In a policy environment emphasising collaborative, recovery-focused and cross-sectoral care (British Medical Association 2014; National Mental Health Commission 2012), it is important that all stakeholders views are sought and considered to determine how to best reform health care to improve access to quality physical health care for people with mental illness.

The process is repeated with the collocation pairs according to their frequency order. The number of the pairs to be shown for each combination type depends on the time allowed for each session.

After lesson exercise: (Time: 10 minutes)

Each lesson ends with the exercise to allow the students to evaluate themselves. The exercise is a multiple-choice generated by the tool available from **Quizlet.com**. The interface of the exercise is shown below.

Lesson 1: Noun + Noun collocations

| The objectives | to introduce students to lexical collocations with | | | | |

Appendix D

Analysis of the Tryout Test

The Analysis of the Tryout of the Nursing Collocation Test

The first two parts of the test were tried out with 38 fourth year Nursing students of academic year 3/2016 at SUT. The first part consisted of 30 items of a multiple choice test. The second part consisted of 20 items of a gap filling test in which the items were sub-divided into four groups of five items. The test descriptions were explained in Thai to the test-takers to make sure they have some ideas about the test they were doing. The results of the test were analyzed to find out three important elements of the test. These elements are the test Difficulty Index, Discrimination Index, and Reliability of the test or the internal consistency coefficients using Kuder-Richardson 20 (KR-20). The results are shown in the table below.

The Nursing Collocation Test Part I

|---|---------|-------|-----|---------|--------|------|------|---|
| | Average | 63.68 | .33 | | | | | ĺ |

Difficulty Index

The tryout test's results of the first part 30 items of multiple choice test reveal that the difficulty index ranges from 7.89 to 97.37 with the average at 63.68. This indicates that the overall test is relatively easy. However, there are four items that the difficulty index values indicate that one of them is a very difficult item and three of them are difficult items. These items are: items no. 5, 6, 11, and 25. The item no. 5 has the lowest difficulty index value at 7.89 indicating that it is very difficult. The items no. 6, 11, and 25 have the difficulty index value at 28.95, 31.58, and 34.21 respectively. Their difficulty indices indicate that they are difficult items. On the other hand, there are also some easy items such as items no. 24 (97.37), 7 (94.74), and 1 and 23 (92. 11). Therefore these items will be examined and revised.

Discrimination Index

There are items that the discrimination index shows that they are needed to be examined and revised. These items are items with the discrimination index value less than 0.2 which indicates poor discrimination ability. The items are item no. 26 (with discrimination index at 0), and items no. 3, 5, 11, 19, 22, 23, 24, and 30 (with discrimination index at 0.1).

Reliability of the Test

The internal consistency coefficients of the test, Kuder-Richardson 20 (KR-20), show the Cronbach's Alpha at .687 which indicates moderate reliability. The Item-total Statistics also show two items which will increase the reliability of the test. These two items are items no. 11 and 26. The two items are clearly problematic as they also appear in both the difficulty index and discrimination index. Therefore, these two items will be examined and revised. ้^{อัก}ยาลัยเทคโนโลยีสุร

Difficulty Index

The try out test's results of the second part 20 items of a gap-filling test reveal that the difficulty index ranges from 21.05 to 86.84 with the average at 55.4. This indicates that the overall test for this part is moderate, neither too difficult nor too easy.

Discrimination Index

The discrimination index shows that there is no item that has the discrimination index value less than 0.2 with the average value at 0.39 which indicates good items.

*ขา*ลยเทคโนโลย*ง*

Reliability of the Test

The internal consistency coefficients of the test, Kuder-Richardson 20 (KR-20), show the Cronbach's Alpha at .602 which indicates moderate reliability. The Item-total Statistics do not show any items which will significantly increase the reliability of test if deleted.

Since the format of the test in this part is gap-filling with collocates provided for each set of five pairs, coupled with the three indices above indicate that the test is in satisfactory level, only minor changes will be made for this part of the test.

Appendix E

Nursing collocation Test

The test consists of three parts:

| Part I, 30 items of a n | nultiple-choice format; | | |
