MATERIALS AS NON-DOPED EMITTERS FOR ORGANIC LIGHT-
EMITTING DIODES. THESIS ADVISOR : ASST. PROF. THANAPORN
MANYUM, Ph.D. 291 PP.

DIKETOPYRROLOPYRROLE/DIPHENYL SULFONE/BENZOTHIADIAZOLE/
DENDRIMER/TADF/AGGREGATION-INDUCED EMISSION/OLED

The aim of this study is the development of new emitting materials including the design, synthesis, and characterization of high-efficiency and long-life emitters. We mainly focus on the molecular design and synthesis of the OLED materials based on the Donor-Acceptor-Donor (D-A-D) system in order to improve the emissive ability, the thermal stability of the material, and overcome π - π stacking interactions of the molecules. The desired structures were composed of diketopyrrolopyrrole (DPP), diphenyl sulfone (DPS), and benzothiazole derivatives as an acceptor and carbazole derivatives or tetraphenylethylene (TPE) as a donor. The photophysical, thermally activated delayed fluorescence (TADF), aggregation-induced emission (AIE) and electrochemical properties of these materials were characterized by UV-vis, time-resolved fluorescence spectroscopic and cyclic voltammetry analyses. Moreover, the investigation of the device fabrication and performance using these materials as an emitter is also reported. The results of this research showed that all diphenyl sulfone derivatives revealed TADF characteristics with the deep blue emission color. Thermal evaporation processed OLED using G1DPP (**2**) as an emitter exhibited an excellent current efficiency of 9.26,

IV

maximum luminance of 1993, and EQE of 2.90%. Furthermore, OLED devices based on all AIE emitters exhibited a high external quantum efficiency in the range of 3.14-4.66%.

ACKNOWLEDGEMENTS

I wish to express my admiration and appreciation to Prof. Dr. Vinich Promarak and Asst. Prof. Dr. Thanaporn Manyum, my advisors for their suggestions, supervision, guidance, and encouragement throughout this work.

I would like to thank the thesis committee, Asst. Prof. Dr. Chanokporn Phaosiri, Asst. Prof. Dr. Tinnakorn Keawin, Dr. Anyanee Kamkaew, and Prof. Dr. James R. Ketudat-Cairns for their valuable discussions and comments on this thesis.

A special thanks to Udon Thani Rajabhat University for financial support. Moreover, this research work was received a graduate research grant from the National Research Council of Thailand (NRCT) 2018. Gratitude is expressed to all of my teachers for showing me a different line in life as a Ph.D. student. My sincere thanks are expressed to the Smart organic materials & semiconductor devices Laboratory (SMS), Vidyasirimedhi Institute of Science and Technology (VISTEC) for all support during the laboratory work and School of Chemistry, Suranaree University of Technology for the wonderful academic environment during the course work.

My appreciation is extended to all staff of the School of Chemistry and SMS Laboratory, my friends, sisters, and brothers in the lab.

Most of all, I feel appreciate and grateful to my beloved family, mom, and dad for their inculcation and encouragement that provided me with fortitude.

Wipaporn Kitisiworaphan

CHAPTER I

INTRODUCTION

1.1 The synthesis of organic light-emitting diodes (OLEDs) materials

The application of organic materials in organic light-emitting diodes (OLEDs) have received increasing interest, since the first report by Ching W. Tang and Steven Van Slyke in 1987 (VanSlyke, 1987), due to their high potential applications in solid-state lighting and flat-panel displays (Mitschke and Bäuerle, 2000; So, Kido, and Burrows, 2008). The OLED displays provide high efficiency, low driving voltage, flexibility, transparency, low weight, etc (H. J. Kim, Shin, Kim, Kim, and Kim, 2017), (Udagawa, Sasabe, Cai, and Kido, 2014), (J. G. Kim et al., 2018). In order to achieve the high efficiencies of electroluminescence (EL) devices, the multilayer structures of OLED devices, doped emitting layers, novel materials, and efficient injection contacts are used (Ma et al., 2002), (Aizawa et al., 2014). However, current trends in the development of OLEDs are focusing on the development of new emitting materials by the design, synthesis, and application of high-efficiency and long-life emitters. In this work, we mainly focus on the molecular design and synthesis of the OLED materials based on the D-A-D system, in which the structure of the desired molecules are composed of diketopyrrolopyrrole (DPP), diphenyl sulfone (DPS), and benzothiazole derivatives as an acceptor, and carbazole derivatives or tetraphenylethylene (TPE) as a donor.

The first series is DPP dendrimers, which are red-emitting materials for OLED. Diketopyrrolopyrrole is a strong acceptor, which exhibits a high molar absorption coefficient, as well as high fluorescence quantum yields, and it can undergo several synthetic modifications (Sharma, Marri, Koyyada, Singh, and Malapaka, 2014). The introduction of the dendronized carbazole derivatives as a donor and end-capping groups increase the solubility in common organic solvent of DPP cores, decrease the π - π stacking interactions, and is used to further tune the properties of the emitters, such as the energy gap, HOMO and LUMO levels. The molecular structures of DPP dendrimers (**1-3**) are shown in Figure 1.1.

Figure 1.1 DPP dendrimer compounds (**1-3**).

Normally, only the singlet excitons of fluorescent materials can emit light, leading to the low efficiency of the OLED devices. Therefore, new materials for

obtaining high efficiency is required. Phosphorescent materials containing heavy metal such as Ir(III), Pt(II), and Os(II), can harvest both singlet and triplet excitons by enhanced spin-orbit coupling (SOC), providing an efficiency close to 100% theoretically (Minaev, Baryshnikov, and Agren, 2014). However, the heavy metals are expensive and non-renewable, resulting in increased cost of the final OLED. Since Adachi and co-workers proposed the mechanisms to harvest both singlet and triplet excitons and avoiding triplet annihilation via the reverse intersystem crossing (ISC) leading to an increase of the fluorescence intensity close to 100%, called thermally activated delayed fluorescence (TADF) (A. Endo et al., 2009). Generally, when the energy gap between HOMO of a donor and the LUMO of an acceptor is small (ΔE_{ST}), reverse intersystem crossing can easily occur. In the second series, we designed the target molecules composed of D-A-D system based on diphenyl sulfone as a core and carbazole derivatives as a donor moiety. The twist angle in the centre of DPS molecules provides a feature for TADF material and the π -linker that inserts between the DPS core and carbazole end groups in order to extend the π -conjugation length and tune the energy gap level. The effect of free rotation of π -linker on TADF property was investigated by varying the number of phenyl substituents in the π -linker. The molecular structures of TADF emitters (**4-13**) are shown in Figure 1.2.

Figure 1.2 TADF emitters (4-13).

After that, the third series, the end group of TADF material was designed to the dendronized carbazole, G1fluorene, and G2fluorene. Because the generation of carbazole dendrons leads three-dimensional molecular conformations and the spatial

distribution of the HOMO and LUMO of the molecule (J. Li et al., 2017). Thus, the expected results when using the TADF dendrimers as the emitter in the OLED device is increased efficiency of the device. The molecular structure of TADF dendrimers (**14-16**) are shown in Figure 1.3.

Figure 1.3 TADF dendrimers (**14-16**).

From above series, we try to tune the property of fluorescent materials to achieve high efficiency of the OLED devices, such as introduce the π -linker to extend the π -conjugation length, use the twist molecules to decrease the energy gap level between HOMO and LUMO, and reduce the π - π stacking interactions by using the carbazole dendron as the end group. However, some fluorophores reveal high emission in the solution state, but their emission was decreased in solid-state caused by aggregated from strong intermolecular π - π interactions, which is also known as aggregation-caused quenching (ACQ) (Peng et al., 2017). To overcome the strong aggregation-caused quenching effect, the small molecules, which can restrict the intramolecular vibration and rotations have been proposed. The aggregation-induced emission (AIE) characteristics found in some propeller-shaped molecules such as siloles and tetraphenylethenes (TPEs) (Y. Liu et al., 2011; Yu, Hsu, and Weng, 2018). Therefore, we designed and synthesized the AIE molecules containing the TPE linked to a variety of acceptors in order to achieve the different emission colors from yellow to red with the strong emission in solid-state. The desired molecules with the D-A-D system consist of benzothiadiazole derivative as electron acceptor bonded to two TPE as AIE unit. Subsequently, aggregation-induced emission characteristics of the target molecules in the THF/water mixtures have been studied as well as their solvatochromic effects related to their structures. The molecular structures of AIE red emitters (**17-26**) are shown in Figure 1.4.

Figure 1.4 AIE red emitters (17-26).

1.2 The principle of OLED

The organic light-emitting diode (OLED) can be used to generate the light sources in display devices, which is not require a backlight to function and have a long operation time. The important advantages are pixels directly emit light and the displays boast of higher brightness and resolution at wider viewing angles. OLED is a thin film optoelectronic device, which is consists of a single layer, double layer or multi-layer of

organic materials sandwiched between two electrodes, one of which must be transparent. Nowadays, the OLED devices are comprised of Anode, hole injection layer (HIL), hole transport layer (HTL), emitting layer (EML), electron transport layer (ETL), hole blocking layer (HBL), and cathode (Thejo Kalyani and Dhoble, 2015; Thejokalyani and Dhoble, 2014). The materials to be used for each layer in OLEDs require the specific properties. The anode material must be transparent with high work function; such as an indium tin oxide (ITO) glass plate. Hole injection material should have high mobility, high glass transition temperature (T_g) and electron blocking capacity. Copper phthalocyanine (CuPc) (27) and 4,4',4''-Tris(3-methylphenylphenylamino)triphenyl amine (*m*-MTDATA) (28). Hole transporting material should possess low ionization potential and high hole mobility; such as *N,N'*-bis(naphthalen-1-yl)-*N,N'*-bis(phenyl)-benzidine (NPB) (29), *N,N'*-bis(3-methylphenyl)-*N,N'*-bis(phenyl)-benzidine (TPD) (30), *N,N'*-bis(naphthalen-1-yl)-*N,N'*-bis(phenyl)-2,2'-dimethylbenzidine (α -NPD) (31) and Di-[4-(*N,N*-ditolyl-amino)-phenyl] cyclohexane (TAPC) (32). Their structures are shown in Figure 1.5.

Figure 1.5 Hole injection materials (27, 28) and hole-transporting materials (29-32).

The emissive material must have high-efficiency, long-lifetime, and color purity, which can be classified into three main classes, they are organic small molecules, polymers, and dendrimers. In order to improve the efficiency of the OLED device, the research trend is focused on design and synthesis of the emissive material. Electron transport materials should have high electron affinities with high ionization potentials in order to transport of electrons by accepting negative charges and allowing them to move through the molecules; such as aluminum tris-8-hydroxy quinoline (Alq_3) (**33**) and 9, 10-di (2-naphthyl)anthracene (ADN) (**34**) as shown in Figure 1.6. The last components are cathode material, which used to inject electrons into emissive layers, and thus must possess a low work function ($\phi_w \approx 2.9\text{--}4.0\text{ eV}$) and low threshold voltage. Mg:Ag (10:1), LiF, Mg:Al, CsF:Al, Al_2O_3 :Al are widely used as cathode materials.

Figure 1.6 Aluminum *tris*-8-hydroxy quinoline (**33**) and 9, 10-di (2-naphthyl)anthracene (**34**).

When a voltage is applied across OLED devices, the injected electrons and holes are transferred into the emissive layer. An exciton is formed when electrons and holes are recombined and generates a photon whose wavelength corresponds to the energy gap after completion of its exciton lifetime. The possibility of electron-hole recombination can be increased by the use of multiple material layers, which electron

and hole can be dammed by using the different of HOMO/LUMO level of material in each layer, therefore recombination position can be controlled, then the high efficiency of OLED can be achieved. Besides that, the emitting color of the OLED device can be tuned by changing the type of organic molecules in the emissive layer and the energy gap of the emitting material. The intensity or brightness of the light depends on the amount of electrical current applied through the device.

The efficiency of OLED is a function of several factors such as a function of the current density, voltage, efficiency of recombination, luminescence quantum yield and the degree of balance charge carrier injection. Luminescence quantum yield (ϕ) is an important parameter in the emission process. It defined as the ratio of the number of photons emitted to the number of photons absorbed, therefore more photons emitted and fewer photons absorbed lead to the high efficiency of the device. Moreover, the performance of the OLED device can be evaluated by several factors such as current-voltage (V - I) characteristics, current density-voltage-luminance (J - V - L) characteristics, electroluminescence (EL) spectra, CIE coordinates, and lifetime measurements.

CHAPTER II

THE SYNTHESIS AND CHARACTERIZATION OF DPP

DENDRIMERS AS EMITTERS FOR ORGANIC

LIGHT-EMITTING DIODES

2.1 Introduction

In this chapter, the structure of 3,6-diphenyl 2,5-dihydro-pyrrolo[3,4-c]pyrrole-1,4 diones, commonly known as DPP, which have been widely used as high-performance pigments such as inks, paints, and plastics has been modified (Figure 2.1) (Iqbal, 1997). DPP derivatives have several advantages such as they are strong acceptors which exhibit a high molar absorption coefficient, as well as high fluorescence quantum yields, and they can undergo several synthetic modifications (Kaur and Choi, 2015). From the above feature, DPP derivatives have been used in polymer solar cells (PSCs) (C. Li et al., 2016), non-fullerene organic solar cells (NFOSCs) (C. Zhao et al., 2019), transistor paint (Nelson et al., 2010), organic photovoltaics (OPV) (S. Qu and Tian, 2012), field-effect transistors (FET) (Malenfant, 2002), sensing fluoride ion and bioimaging (Y. Qu et al., 2014) fluorescent probes (Kaur and Choi, 2015), two-photon absorption (Ftouni, Bolze, de Rocquigny, and Nicoud, 2013), dye sensitizing solar cell (Farré et al., 2016), and organic light-emitting diodes (OLEDs) (Tieke, 2007).

DPP-containing polymers have been used as an emitter for OLED devices, but the small DPP molecule has not been investigated, despite their very high intensity and photoluminescence quantum yield (PLQY) in solution. Owing to DPP has a planar structure induces strong intermolecular H-bonding and π - π stacking with neighboring molecules that may lead to dissipative intermolecular charge transfer and aggravate charge recombination that quenches fluorescence (Data et al., 2016). From our previous work, we reported the red emitter containing carbazole dendrons as the end caps with the oligoarylfluorene cores for OLED, that we are able to reduce the crystallization and retain the high emissive ability of a planar fluorescent core in the solid-state as well as improve the thermal stability of the material.

The light emission can be finely tuned by the selection of the core, solubility can be adjusted by selecting the suitable surface groups and the level of intermolecular interactions can be controlled by the type and generations of the dendrons employed (Sudyoadsuk et al., 2014). The purpose of our current work is, therefore, to report on the new DPP-containing carbazole dendron in order to overcome π - π stacking of DPP molecules and induced to increase the EQE of the OLED device. We synthesized and investigated new solution-processed dendrimer-based red emitters. The DPP dendrimer containing two parts, the first part is 3,6-diphenyl 2,5-dihydro-pyrrolo[3,4-c]pyrrole-1,4 diones (DPP) as a fluorescent core and another part is carbazole dendrimers up to the second generation as end-capping groups. The latter can suppress the aggregation-induced fluorescence quenching of the planar conjugated core as well as increase thermal stability, and solubility of the molecule. With the character of dendron that reduces the π - π stacking interaction of DPP core, the dendrimer molecules will emit in the red region. Previous work, we reported on carbazole dendrimers that are

successfully used as efficient solution-processed materials with a simple structure of OLED devices (Moonsin et al., 2012). With this design, a simple solution-processed red emitter can be obtained and can be fabricated. Herein we report a detailed synthesis of a series of DPP end-capped with carbazole dendrons as well as their physical and photophysical properties. The investigation of the device fabrication and performance using these materials as an emissive layer is also reported. The diaryl groups of DPP molecule reveals several centres of reactivity in the molecule as shown in Figure 2.1. The phenyl rings could undergo electrophilic and nucleophilic substitution reactions, while each of three functional groups, namely double bonds, carbonyl and NH moieties of bicyclic lactam enables chemical transformation. Therefore, the reaction of DPP chromophore is focused on electrophilic aromatic substitution, *N*-substitution and nucleophilic transformations of the carbonyl group without ring-opening of the heterocyclic rings. Currently, the most important member of the DPP class of pigments is pigment red 254 which is a very opaque yellow-red pigment of outstanding outdoor durability, brightness, and resistance to heat and chemicals. Pigment red 254 is widely used for exterior coatings in the automotive industry and plastics (Iqbal, 1997).

Figure 2.1 Centres of potential chemical reactivity in the molecule of DPP (35).

Some DPP derivatives have been synthesized by a chemical reaction such as Suzuki reaction and alkylation. In 2007, five new soluble conjugated polymers (**36-41**) were prepared upon Suzuki polycondensation reactions, which consist of DPP units and carbazole, triphenylamine, benzo[2,1,3]thiadiazole, anthracene, and fluorene units as shown in Figure 2.2. The polymers are soluble in common organic solvents and exhibit brilliant red colors with the photoluminescence quantum yields up to 86% (Tieke, 2007).

Figure 2.2 Conjugated polymers (**36-41**) obtained from the Suzuki reaction.

The DPP derivatives (**41-44**) with mono-alkyl substituted or di-alkyl substituted at *N*-position of lactam rings via *N*-alkylation reaction have been reported in 2008

(Figure 2.3). The studies reveal that the electronic properties strongly depend on the planarity of the molecules, which was decreased by the substitution. A larger Stokes shift was observed when a phenyl torsion increased, and the vibrational structure decreased. On the other hand, the fluorescence quantum yield remains nearly the same, which indicated that the thin film of these DPP compounds can be prepared and used for the construction of efficient electroluminescent devices without loss of fluorescence quantum yields (Vala, Weiter, Vynuchal, Toman, and Lunak, 2008).

Figure 2.3 The DPP derivatives (41-44).

In 2010, Nelson et al. has reported the synthesis of the DPP polymer semiconductor (**45**) with D-A character via the Stille coupling reaction of dibrominated DPP monomer (**46**) with distannylated DTP monomer (**47**) as shown in Figure 2.4. The expected result was to enhance charge mobility and achieved a narrow bandgap by the use of D-A system. The new polymer exhibited hole mobility as high as $0.41 \text{ cm}^2/\text{Vs}$ and average mobility of $0.29 \text{ cm}^2/\text{Vs} \pm 0.04$ for channel lengths of 30–40 μm (Nelson et al., 2010).

Figure 2.4 The synthesis of DPP polymer semiconductor (**45**).

The unsubstituted DPP (**35**), symmetrically *N*-substituted DPP (**48**, **50**, and **52**), and asymmetrically *N*-substituted DPP (**49** and **51**) were investigated using thermogravimetry (TGA) and differential scanning calorimetry (DSC) (David, Weiter, Vala, Vyňuchal, and Kučerík, 2011). The results reveal that the different alkyl chains and symmetry of the *N*-substitution effect on physical-chemical properties, which the shorter the alkyl chain and the symmetrical derivatives display less stability. On the other hand, DSC experiments did not reveal the presence of different crystalline structures in DPP.

Figure 2.5 The unsubstituted DPP (**35**), symmetrically *N*-substituted DPP (**48**, **50**, and **52**), and asymmetrically *N*-substituted DPP.

In 2014 Data et al. was able to improve the efficiency of OLED by creating exciplex emitters from dilution of DPP compounds in TAPC and CBP hosts. The results reveal that the external quantum efficiency of the OLED device with exciplex emitter (12%) is higher than the pure compound (0.2%) (Data et al., 2016).

The near-infrared (NIR) OLED based on NIR emitting diketopyrrolopyrrole borondifluoride cyanine emitter (**54**) has been reported by Sassi et al. in 2016. By incorporating of DPP derivative with NIR chromophores was obtained EQE of 0.55% with no efficiency roll-off and stability for long operation time (Sassi et al., 2016).

Figure 2.6 The synthesis of diketopyrrolopyrrole borondifluoride cyanine emitter (**54**).

Podlesný et al. was designed and prepared the diketopyrrolopyrrole based D- π -A- π -D molecules with quadrupolar chromophores by Suzuki-Miyaura, Migita-Stille, and Sonogashira cross-coupling reactions to afford nine compounds (**55-63**). The properties such as differential scanning calorimetry, electrochemistry, and absorption and emission spectra can be tuned by structural variation of the peripheral substituents (donor) and enlargement of the π -system. The results revealed that the thermal stability is mostly affected by the presence of π -linkers and ferrocene end groups. The variation of donors influences the effect on the HOMO-LUMO gap (Podlesny et al., 2017).

Figure 2.7 The diketopyrrolopyrrole based D- π -A- π -D molecules (55-63).

The optical, electronic, and charge transport properties of a series of donor-acceptor diketopyrrolopyrrole derivatives (64-70) have been investigated. The introduction of the various donor end groups of the designed compounds can broaden the absorption spectrum and improve the charge transport property. The results can be concluded that the DPP derivatives were suitable for use as donor materials for OSCs and luminescent materials for OLEDs (Jin, Zhang, Xiao, and Irfan, 2018).

Figure 2.8 The diketopyrrolopyrrole derivatives (64-70).

2.2 Research objectives

2.2.1 To design, synthesize and characterize novel fluorescence materials as a non-doped emitter for OLED.

2.2.2 To study the photophysical, electrochemical, and thermal properties by using UV-Visible spectroscopy, fluorescence spectroscopy, cyclic voltammetry, and DSC-TGA techniques.

2.3 Synthesis

2.3.1 Synthetic procedure

Therein we also reported the synthesis of the DPP dendrimer derivatives by Friedel-Craft alkylation of carbazole to afford key intermediate followed by Ullmann *N*-arylation to achieve the carbazole dendron. Finally, the *N*-alkylation of DPP with the key intermediate to afford the corresponding compounds (Figure 2.9).

Figure 2.9 Synthetic approach to the synthesis of DPP dendrimers.

2.3.2 Preparation of 3,6-diiodo-9-tosyl-carbazole (72)

3,6-diiodo-9-tosyl-carbazole (**72**) could be synthesized on a 10 g scale in two steps starting from the inexpensive carbazole (**71**) according to a simple procedure (Figure 2.10).

Figure 2.10 The synthesis of 3,6-diiodo-9-tosyl-carbazole (**72**).

Iodination of carbazole (**71**) with potassium iodide and potassium iodate in acetic acid provided the corresponding 3,6-diiodo carbazole, which protects N atom of carbazole with tosylate group by using *p*-toluenesulfonyl chloride and potassium hydroxide in acetone. After purification by recrystallization from CH₂Cl₂/hexane the desired product was obtained in 64% overall yield.

2.3.3 Preparation of 3,6-di-*tert*-butyl-carbazole (73)

3,6-di-*tert*-butyl-carbazole (**73**) or G1 could be synthesized on a 10 g scale, which starting from the Friedel-Craft alkylation of inexpensive carbazole (**71**) as shown in Figure 2.11.

Figure 2.11 The synthesis of 3,6-di-*tert*-butyl-carbazole (**73**).

Friedel-Crafts alkylation involves C-C bond formation of an aromatic ring with an alkyl halide using a strong Lewis acid, such as aluminium chloride, ferric chloride, as a catalyst. The general mechanism is shown in Figure 2.12.

Figure 2.12 The proposed mechanisms of Friedel-Crafts alkylation.

Friedel-Craft alkylation of carbazole (**71**) with 2-chloro-2-methyl propane and zinc chloride in the mix of CH_2Cl_2 and nitromethane in a ratio of 2:1 provided the corresponding 3,6-di-*tert*-butyl-carbazole (**73**). After purification, by washing with hexane the desired product was obtained in a yield of 72%.

2.3.4 Preparation of G2 (**74**)

The second generation of dendron (**74**) could be synthesized on a 5 g scale from the Ullmann *N*-arylation of **G1** (**73**) as shown in Figure 2.13.

Figure 2.13 The synthesis of G2 (**74**).

Ullmann coupling reaction is a copper-catalyzed cross-coupling reaction in respect of C-C bond formation between two molecules which one of these is aryl halides (Mondal, 2016). Therefore Ullmann *N*-arylation is a coupling reaction of aryl halides with amines by using CuI-catalyzed to create C-N bond (Dawei Ma, 2003; Eric R. Strieter, 2009). The proposed mechanisms of the Cu(I)-catalyzed C-N bond-forming reaction between *N*-nucleophiles and aryl halides involves 2 steps, nucleophile formation and Cu(I)-mediated nucleophilic aromatic substitution (Figure 2.14).

Figure 2.14 The proposed mechanisms of Ullmann *N*-arylation.

A stoichiometric reaction of G1 (**73**) (2.3 equiv) and 3,6-diiodo-tosylcarbazole (**72**) (1 equiv) using CuI as the catalyst, (\pm)-*trans*-1,2-diaminocyclohexane as the co-catalyst and K_3PO_4 as base in toluene followed by deprotection of the intermediate compound with 3 M potassium hydroxide in THF/DMSO provided the corresponding G2 (**74**) in a moderate yield of 62%.

2.3.5 Preparation of G1hexyl bromide (**75**) and G2hexyl bromide (**76**)

The Gnhexyl bromide (**75** and **76**) could be prepared on a 1 g scale by *N*-alkylation of Gn with 1,6-Dibromohexane in as shown in Figure 2.15.

Figure 2.15 The synthesis of G1hexyl bromide (**75**) and G2hexyl bromide (**76**).

N-alkylation or Amine alkylation is a reaction between an alkyl halide and amine to afford the higher substituted amine product. This reaction is called nucleophilic aliphatic substitution and the proposed mechanisms are shown in Figure 2.16.

Figure 2.16 The proposed mechanisms of *N*-alkylation.

The alkylation of G1 and G2 with 1,6-dibromohexane in the presence of potassium hydroxide in *N,N*-dimethylformamide at room temperature provided the corresponding G1hexyl bromide (**75**) and G2hexyl bromide (**76**). After purification by column chromatography using CH_2Cl_2 /hexane as the eluent to afford the products as a white solid in the yields of 77% and 86%, respectively.

2.3.6 Preparation of GnDPP (1-3)

The desired DPP compounds could be synthesized on a milligram scale by using *N*-alkylation of pigment red 254 (**77**) with potassium *tert*-butoxide in *N*-methyl-2-pyrrolidone (NMP) to give corresponding GnDPP (**1-3**) in a low yield as depicted in Figure 2.17.

Figure 2.17 The synthesis of GnDPP (1-3).

Nucleophilic substitution of pigment red 254 (77) with alkyl bromide in the presence of potassium *tert*-butoxide as base in *N*-methyl-2-pyrrolidone (NMP) at 60 °C for 18 hours to afford the desired products. After purification by column chromatography and recrystallization from CH₂Cl₂/MeOH yielded the yellow-orange colored solid of G0DPP (1), G1DPP (2), and G2DPP (3) in the yields of 50%, 14%, and 26%, respectively. All products were soluble in most organic solvents and their structures were confirmed by ¹H NMR as shown in Figure 2.18.

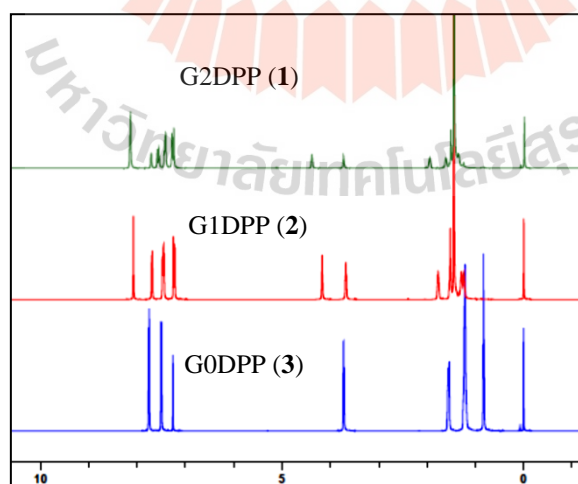

Figure 2.18 The ¹H-NMR spectrum of GnDPP (1-3).

The structure of G0DPP (**1**) was confirmed by ^1H -NMR spectroscopy. The diaryl protons of the DPP core exhibited two doublets peak at $\delta = 7.76$ (4H) and 7.50 (4H) ppm with the coupling constant (J) of 8.4 Hz. The alkyl protons at the near position with N-atom of DPP core show the signals at $\delta = 3.72$ (4H, t), while another position displays the signal at $\delta = 1.56$ (4H, m), 1.21 (12H, m), 0.83 (6H, m) ppm. Besides, ^{13}C -NMR reveals the chemical shift of the signals of diaryl carbons was in the range of 162.5- 110.0 ppm and the alkyl carbons were in the range of 41.9-13.9 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 524.4251 (required m/z = 524.1997).

The ^1H -NMR spectrum of G1DPP (**2**) exhibited the characteristic singlet peak of G_1 protons with the chemical shift at 8.09 (4H) ppm and the chemical shift of another position of G_1 protons was in the range of 7.45-7.23 ppm. The diaryl protons of DPP core exhibited two doublets peak at $\delta = 7.70$ (4H) and 7.49 (4H) ppm with the coupling constant (J) of 8.3 Hz. The alkyl protons at the near position with N-atom of DPP core show the triplets signals at $\delta = 3.72$ (4H) and the methylene protons which near the N-atom of G_1 show the triplets signals at $\delta = 3.69$ (4H), while another position display the signal at $\delta = 1.78$ (4H), 1.53 (4H) 1.45 (36H), and 1.24-1.30 (8H) ppm. Besides, ^{13}C -NMR reveals the chemical shift of the signals of diaryl carbons was in the range of 162.4-107.9ppm and the alkyl carbons were in the range of 42.9-26.6 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 1078.6823 (required m/z = 1078.5658).

The ^1H -NMR spectrum of G2DPP (**3**) exhibited the characteristic singlet peak of the second generation of the dendron protons with the chemical shift at 8.17 (8H) ppm, singlet peak of first generation of the dendron protons at 8.15 (4H). The

chemical shift of another position of G2 protons and diaryl protons of DPP core was in the range of 7.73-7.30 ppm. The alkyl protons at the near position with N-atom of DPP core show the triplets signals at $\delta = 4.40$ (4H) and the methylene protons which near the N-atom of G1 show the triplets signals at $\delta = 3.73$ (4H), while another position was in the range of 1.61-1.26 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 1963.0941 (required m/z = 1963.0476).

2.4 Results and discussion

2.4.1 Quantum chemical calculation

Quantum chemical calculations performed using the B3LYP/6-311G(d,p) method²⁶ reveal that increasing of the generation of the dendron surrounding the DPP acceptor produced sterically hindering molecular structures increased (Figure 2.19). The distributions of π -electrons in the HOMOs of G₁DPP and G₂DPP are mainly located on the carbazole dendron moieties, while in the LUMOs of two compounds, the excited electrons are localized on the DPP moieties. On the other hand, both HOMOs and LUMOs of G₀DPP (**1**) that have only alkyl chain linked to DPP moiety, π -electrons are located on the DPP moiety. The HOMOs and LUMOs of the DPP dendrimers estimated from the calculation are summarized in Table 2.1. According to the TDDFT, it can be deduced that G₀DPP (**1**), G₁DPP (**2**), and G₂DPP (**3**) would have similar electronic properties with different physical properties.

Figure 2.19 HOMO and LUMO orbitals of G0DPP (1), G1 DPP (2), and G2 DPP (3) calculated by the B3LYP/6-31G(d,p) method.

Table 2.1 HOMOs and LUMOs of the DPP dendrimers estimated from the calculation.

Compds	HOMO (eV)	LUMO (eV)
G0DPP (1)	-5.360	-2.561
G1DPP (2)	-5.128	-2.690
G2DPP (3)	-5.013	-2.757

2.4.2 Optical properties

The UV-vis absorption and fluorescence spectra of the DPP dendrimers were investigated in dilute toluene solution (10^{-5} M) and the neat film by UV-vis and photoluminescence spectroscopies as shown in Figure 2.20. Absorption spectra of G1DPP (2) and G2DPP (3) exhibit two major absorption bands, a high absorption band around

300 nm assigned to the π - π^* transition of the dendrimers and an absorption band at 480 nm corresponding to the π - π^* transition of the lactam unit of DPP. Moreover, the UV-vis of G0DPP (**1**) showed the strong absorption band of the π - π^* transition of the lactam around 480 nm. Both of GnDPP dendrimers showed similar absorption band in solution and in the neat film. This indicates that the dendron which is substituted on the DPP chromophore does not induce the bathochromic effect on the UV-vis spectra.

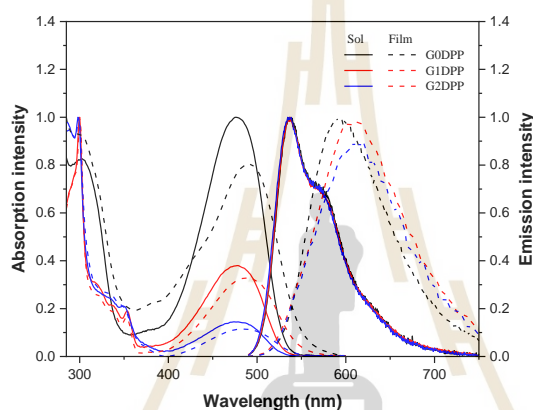

Figure 2.20 UV-vis absorption and fluorescence spectra of (a) G0DPP (**1**) (b) G1DPP (**2**) and (c) G2DPP (**3**) in dilute toluene solution (10^{-5} M) and in a solid film.

The optical band gap of these dendrimers has been calculated from the onset wavelength of absorption. The detailed optical data of all compounds are summarized in Table 2.2. Photoluminescence spectra of G0DPP (**1**), G1DPP (**2**), and G2DPP (**3**) showed an emission band in the toluene solution at 537, 536, and 536 nm, respectively, while in the neat film are 595, 610, and 610 nm. They show the bathochromic shift from the solution to the solid-state (58, 72, and 72 nm for G0DPP (**1**), G1DPP (**2**), and G2DPP (**3**)). Furthermore, they display the large stoke shift with 61, 58, and 58 nm in solution and 104, 118, and 122 nm in the neat film, respectively. Therefore, the introduction of

the carbazole dendron with the longer alkyl chain at N-atom of the lactam unit lead to reduce the π - π stacking interaction of the planar molecule in the solid-state and increase their solubility.

The Commission Internationale De L'Eclairage (CIE) Chromaticity diagram describes the color perceived by the human eye in full daylight, which the chromaticity coordinates of samples represented by (x,y). These values can be calculated by $x = X/(X + Y + Z)$, $y = Y/(X + Y + Z)$ where (X,Y,Z) represents a CIE XYZ tristimulus vector. (Sovdat, Kadunc, Batič, and Milčinski, 2019) (Ji, Xue, and Cui, 2015) The CIE coordinates of the emitted orange light in the neat film are (0.56, 0.44), (0.54, 0.45), and (0.57, 0.43) for G0DPP (1), G1DPP (2), and G2DPP (3), respectively as shown in the Figure 2.21 and Table 2.3.

Transient photoluminescence spectra of all dendrimers in solution and neat film are shown in figure 2.20 and the lifetime is summarized in Table 2.2. From the

studies, these dendrimer molecules display only prompt fluorescence with the short fluorescence lifetime (nanosecond) either the solution or neat film. Moreover, the G0DPP (**1**) and G1DPP (**2**) have shown a longer lifetime in solution state and a slight decrease when changing to the solid-state. In contrast, G2DPP (**3**) has a longer lifetime in solid-state. The reason could be due to that, the bulky molecule of G2 dendron leads to decrease π -stacked aggregation of the molecules in solid-state. Thus, the planarization of G2DPP (**3**) was decreased, exhibiting the longer fluorescence lifetimes (Ji et al., 2015).

2.4.3 Electrochemical properties

The redox properties of these Dendrimers and their HOMO and LUMO energy levels were investigated by cyclic voltammetry (CV) analysis. The measurements were carried out in CH_2Cl_2 solution containing 0.1 M $\text{n-Bu}_4\text{NPF}_6$ as supporting electrolyte using three-electrode systems under an argon atmosphere. The reference electrode was Ag/Ag^+ . The results are shown in Figure 2.22 and summarized in Table 2.4. All dendrimers exhibit reversible oxidation processes upon the anodic sweep with a half potential of 1.23 and 1.47 for G0DPP (**1**), 1.15 and 1.52 for G1DPP (**2**), and 1.02, 1.20, and 1.50 for G2DPP (**3**). The HOMO levels of all these molecules calculated from the onsets of the oxidation potentials were -5.80, -5.50 and -5.38 eV, respectively. Moreover, they display two chemically reversible reduction with a half potential of -1.20 and -1.73 for G0DPP (**1**), -1.19 and -1.75 for G1DPP (**2**), and -1.18 and -1.77 for G2DPP (**3**). The LUMO levels of all these molecules calculated from the onsets of the reduction potentials were -3.33, -3.35, and -3.39 eV, respectively. The corresponding optical band gaps (E_g^{ele}) were 2.26, 2.14, and 1.99, respectively. The ratio between the peak current of the first reduction and the first oxidation of G0DPP (**1**) is almost 1, in which the potentials and reversibility of the redox peaks are similar to the reported molecules. We assume that the charge species are high stable lead to form the radical cation and anion during the redox process, and the second oxidation step generates a dicationic species. The two oxidation/reduction potentials assigned to the DPP residues. Furthermore, both of DPP dendrimers exhibit the redox potentials as same as G0DPP (**1**), however they display the third oxidation peak assigned to the dendron residues.

2.4.4 Thermal properties

The thermal properties of these dendrimers were determined by thermal gravimetric analysis (TGA) and differential scanning calorimetry (DSC) as shown in Figure 2.23. The results reveal that all molecules exhibit high thermal stability with the decomposition temperatures at 5% weight loss (T_{5d}) of 356, 409, and 432°C, for G0DPP (1), G1DPP (2), and G2DPP (3), respectively.

Figure 2.23 TGA curves of G0DPP (1), G1DPP (2), and G2DPP (3) with heating rate of 10°C/min under a nitrogen atmosphere.

2.4.5 Electroluminescence properties

In order to investigate the electroluminescence properties of G_n DPP dendrimers, OLED devices were fabricated with the following device structure: indium tin oxide (ITO)/PEDOT:PSS/mCP or mCBP (20nm)/EML(20 nm)/Bphen(20 nm)/LiF(0.5 nm):Al(150 nm), where these materials were used as the emitting layer (EML) as shown in Figure 2.24. Conductive polymer poly(3,4-ethylenedioxy thiophene): poly(4-styrenesulfonate) (PEDOT: PSS) as hole injection layer, 1,3-bis(N-carbazolyl) benzene (mCP) or 3,3-di(9H-carbazol-9-yl)biphenyl (mCBP) as hole transporting layer, and 4,7-Diphenyl-1,10-phenanthroline (Bphen) or 3-(4-Biphenyl)-

4-phenyl-5-*tert*-butylphenyl-1,2,4-triazole (TAZ) as hole-blocking layer were also used to enable high-performance devices. The electroluminescence spectra (EL) of all dendrimers doped in 3% mCP showed similar features with their fluorescence spectra without the emission of the host materials as shown in Figure 2.24.

Figure 2.24 Schematic energy diagram and electroluminescence spectra of all dendrimers doped in 3% mCP.

The quantum yield of these dendrimers in neat film and doped mCP and mCBP film with the blending ratio ranging from 1%wt to 2%wt are summarized in Table 2.5. The layers were spin-coated from a CHCl_3 /toluene (1:1) solution with controlled thickness. The neat film of these molecules either 1 wt% or 2wt% shows a low quantum yield. However, the doped film with mCP and mCBP induce to reach a higher yield. Moreover, the doped film with 1 wt% of mCP of all these compounds shows the highest quantum yield, thus mCP is used as hole transporting layer in the device.

Table 2.5 Quantum yield of DPP dendrimers in neat film and doped film.

Compds \ QY	Neat film		Doped with mCP		Doped with mCBP	
	2 wt%	1 wt%	2 wt%	1 wt%	2 wt%	1 wt%
G0DPP (1)	8.96	5.29	21.07	50.09	28.26	46.68
G1DPP (2)	4.48	3.44	64.87	57.45	37.75	49.41
G2DPP (3)	8.86	5.14	39.43	53.03	47.24	41.31

Normally, the diketopyrrolopyrrole (DPP) core is non-soluble in a most organic solvent, therefore the dendron substituents are introduced to the designed molecules in order to improve the solubility of these molecules. These dendrimers exhibit high solubility in most organic solvents allowing their thin films to be fabricated by a solution casting process, thus overcoming the high cost of the vacuum deposition process. The morphology of the spin-casting films, which is another key factor for the OLED fabrication, was examined by atomic force microscopy (AFM). The AFM images of all thin films spin-coated from the CHCl_3 /toluene (1:1) solution show a smooth surface indicating excellent films forming properties (Figure 2.25). The AFM image of the thin film of G1DPP (2) blends with mCP shows a very uniform and smooth surface with the root mean square roughness (RMS) of 0.29 nm, indicating excellent film-forming properties. Furthermore, the surface of the spin-coated film of the G0DPP (1) and G2DPP (3) blends with mCP have a more surface roughness with RMS of 0.47 and 0.48 nm. This suggests that G1DPP (2) form a more homogeneously distributed morphology when mixed with mCP, which provides enhanced exciton dissociation (Más-Montoya and Janssen, 2017).

Figure 2.25 Tapping mode AFM images of the spin-coated films.

The multi-layer devices using G_n DPP dendrimers as EMLs with the structure of ITO/PEDOT:PSS//mCP (20nm)/EML(20 nm)/Bphen or TAZ(20 nm)/LiF(0.5 nm):Al(150 nm) were fabricated. The solution-processed of G0DPP (**1**), G1DPP (**2**), and G2DPP (**3**) OLEDs emit yellow light with the $\lambda_{\text{max}}^{\text{EL}}$ around 550 nm. No emission shoulder at a longer wavelength due to excimer and exciplex species formed at the interface of the EML and ETL layers, which often occurs in devices fabricated from EMLs with a planar molecular structure, is detected. The CIE coordinates of the emitted lights are (0.407, 0.485) for the G0DPP (**1**)-based OLED (device IV), (0.415, 0.483) for the G1DPP (**2**)-based OLED (device V) and (0.408, 0.510) for the G2DPP (**3**)-based OLED (device VI). The spin-coated multi-layer OLED using G1DPP (**2**) (device V) as the EML exhibits a massive improvement in the device performance compared to its multi-layer without PVK (device I) with a L_{max} of 1993 cd m^{-2} , V_{max} of 9.4 cd m^{-2} , J_{max} of 96 mA/cm^2 , and EQE_{max} of 2.90.

2.5 Conclusion

In summary, the synthesis of diketopyrrolopyrrole carbazole dendrimers for OLED has been succeeded. By using the alkyl group linked to the DPP core, we are able to obtain the high solubility of the emitters. Increasing the generation of the carbazole dendrimers (1st and 2nd generations) as a scaffold, we retain the high emissive ability and reduce the π - π stacking interaction of DPP fluorophore as well as improve amorphous glass-forming ability, solution processability and thermal stability of the material. The G1DPP (**2**) exhibit a strong red emission with thermal stability (T_{5d} 411°C). These results revealed that G1DPP (**2**) is promising as red emitter for high-efficiency OLEDs with much simpler device architecture. We believe that our results could provide useful guidance to decorate the highly efficient but planar fluorophore to be suitable for applications in OLEDs devices.

CHAPTER III

THE SYNTHESIS AND CHARACTERIZATION OF NOVEL THERMALLY ACTIVATED DELAYED FLUORESCENCE MATERIALS FOR ORGANIC LIGHT-EMITTING DIODES

3.1 Introduction

Organic light-emitting diodes (OLEDs) are widely used in almost every kind of display such as mobile phones, television, cameras, watch, and wearable devices. Although the OLEDs have a lot of benefits whether it be flexible, thin, and small in size hence are very easy to manufacture OLED displays, but these materials have some weak points such as a shorter lifetime, easily damaged by water, and can be degraded by light. The limited lifetime of the organic materials is the biggest technical problem of OLEDs. The study of the stability of red, green and blue phosphorescent OLED emitters revealed that the photodegradation rate of blue emitters is higher than red and green emitters, thus the lifetime of a blue emitter is shorter than the red and green emitter (Schmidbauer, Hohenleutner, and Konig, 2013). A short lifetime leads to the low efficiency of OLED, red (625 nm), green (530 nm) and blue (430 nm) diodes exhibit an external quantum efficiency value of 20%, 19%, and 4% to 6%, respectively (Bagher, 2014). Therefore, the research for investigating efficient blue emitter as well as deep blue color is required.

Generally, fluorescence materials can harvest only 25 % of singlet exciton under electrical excitation, so the external EL efficiencies (η_{EL}) are intrinsically limited to approximately 5% (A. Endo et al., 2009). On the other hand, OLEDs that use phosphorescent materials such as Ir and Pt complexes can harvest both singlet and triplet exciton and achieved η_{exciton} of almost 100% (Kawamura et al., 2005).

However, phosphorescent materials containing heavy metals are rather expensive and unsustainable. Besides that, the toxicity of heavy metal effect the environmental. Therefore, since both fluorescence- and phosphorescence-based OLEDs have both advantages and disadvantages, the use of a novel light-emitting mechanism has been hoped for to avoid the shortcomings.

In 2008, Baleizao and Berberan-Santos reported the second mechanism for fluorescence from fullerenes, which is called thermally activated delayed fluorescence (TADF). The results reveal that the photophysical properties of fullerene C_{70} exhibited the strong TADF characteristic, the small ΔE_{ST} gap, and the long intrinsic phosphorescence lifetime, especially triplet formation (Φ_{T}) very close to 1 (Baleizao and Berberan-Santos, 2008). After that, Adachi and co-worker proposed a mechanism to enable internal electroluminescence quantum efficiency (η_{int}) 100% without using phosphorescent materials by using reverse intersystem crossing (RISC) from triplet (T_1) to singlet excited states (S_1) as shown in Figure 3.1 (A. Endo et al., 2009).

Figure 3.1 Schematic view of the reverse intersystem crossing mechanism.

When applied an electrical across two-electrode of OLED, which consists of cathode and anode. Electrical charge carriers of both polarities were injected into the organic layers originated electrons and holes. The electrons and holes transport and recombination produced light. Because exciton formation under electrical excitation results in 25% singlet excitons and 75% triplet excitons, internal electroluminescence quantum efficiency (η_{int}) 100% was obtained by converse from triplet excitons to singlet excitons via RISC, so small the energy gap of the RISC (ΔE_{ST}) is required as shown in Figure 3.2. Moreover, the lifetime of the triplet excitons has too long enough. Normally, ΔE_{ST} is proportional to the exchange energy between the highest occupied molecular orbital (HOMO) and the lowest unoccupied molecular orbital (LUMO) in the molecules, thus a small ΔE_{ST} can be achieved by separating the HOMO from the LUMO because the exchange energy decreases exponentially with increasing HOMO-LUMO (electron-hole) separation distance (Goushi, Yoshida, Sato, and Adachi, 2012).

Figure 3.2 Energy alignment of singlet and triplet energy levels to achieve efficient TADF (Adachi, 2014).

In this chapter, we design the TADF molecules composed of donor-acceptor-donor (D-A-D) systems in order to spatial separated HOMO and LUMO to minimize the exchange integrals between the two orbitals. The best method for separating the spatial distribution of HOMO of donor and LUMO of the acceptor is to use the twisted molecule as the bridge between the donor and the acceptor moieties. Due to, the twist angle between the donor and acceptor planes increased lead to a decrease in the energy gap. However, a large twist angle generally suppresses the intensity of fluorescence decay and leads to a decrease in the internal EL efficiency of the devices (Rajamalli et al., 2016). Therefore, the donor-acceptor-donor (D-A-D) system was designed for reducing the ΔE_{ST} and retain intramolecular space interaction. We expect that the desired molecules with TADF character can be used as emitters in the emitting layer of an OLED to achieve high external EL efficiencies (η_{EL}), high-performance in flexibility over a large area, low-cost fabrication, and high optical and electrical properties.

The thermally activated delayed fluorescence which is previously named as E - type delayed fluorescence was believed to discover from the eosin dye (78) in 1961

(Parker and Hatchard, 1961). It is the first purely organic TADF material, the molecular structure is shown in Figure 3.3.

Figure 3.3 The molecular structure of the eosin dye (**78**).

In 1980, the first metal-containing TADF material has been reported. The molecular structure is shown in Figure 3.4. The luminescence spectra and decay times of the emission of *bis* (triphenylphosphine) phenanthroline copper (I) ion (**79**) have been measured in liquid helium. The long decay time at low temperatures is interpreted in terms of the triplet level of the charge-transfer state (Blasse and McMillin, 1980).

Figure 3.4 The molecular structure of the *bis* (triphenylphosphine) phenanthroline copper (I) (**79**).

In 1996, the delayed thermal fluorescence was founded in fullerenes, owing to this mechanism induced the fluorescence quantum yield of C_{70} increases by one or two orders of magnitude (from $\Phi_F = 5 \times 10^{-4}$ up to $\Phi_F = 0.08$) (Berberan-Santos and Garcia, 1996). After that, in 2008 the fullerene C_{70} was used as the temperature and oxygen sensors (Baleizao and Berberan-Santos, 2008).

In 2009, the new TADF materials were reported as the emitter in OLED devices. Six complexes of tin(IV) fluoride-porphyrin (SnF_2 -porphyrin) are octaethylporphine (OEP), etioporphyrin I (Etio I), hematoporphyrin IX (Hemato IX), protoporphyrin IX (Proto IX), mesoporphyrin IX (Meso IX), and Copro III as shown in Figure 3.5. These SnF_2 -porphyrin complexes exhibited a rather strong TADF at room temperature and displayed an increase in fluorescence intensity with increasing temperature (A. Endo et al., 2009).

Figure 3.5 Molecular structures of the six Sn(IV)-porphyrin complexes **80-85**.

After successfully synthesizing the TADF materials, this approach is a general concept for designed the fluorescence materials to provide OLEDs with high EL efficiency. The variety of TADF molecules can be designed and synthesized rationally, which are discussed as follow;

In 2011, the purely aromatic compounds, 2-biphenyl-4,6-bis(12-phenylindolo[2,3-a]carbazole-11-yl)-1,3,5-triazine (PIC-TRZ) (**86**) that exhibit highly efficient TADF have been reported. The molecules containing an indolocarbazole donor unit and a triazine acceptor unit in which the introduction of bulky groups leads to occur steric hindrance effect that can distort π -conjugation. The highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO) orbitals can be located around donor and acceptor moieties, respectively, leading to a small ΔE_{ST} (0.11 eV). The molecular structure of PIC-TRZ (**86**) is shown in Figure 3.6 (Ayataka Endo et al., 2011).

Figure 3.6 Molecular structure of PIC-TRZ (**86**) and its HOMO and LUMO calculated by Gaussian 03.

The exciplex between *m*-MTDATA (**87**) and ^tBu-PBD (**88**) was used as an emitter in EML of the OLED device. They show a very high RISC of 86.5% between triplet and singlet excited states. OLEDs device made using *m*-MTDATA as the donor material and 3TPYMB (**89**) as the acceptor material produced the external quantum efficiencies of 5.4% (Goushi et al., 2012). The molecular structures and formation of exciplex state between *m*-MTDATA and 3TPYMB are depicted in Figure 3.7.

Figure 3.7 The molecular structures and formation of exciplex state between *m*-MTDATA (**87**) and 3TPYMB (**89**).

The several TADF materials have been designed and synthesized based on the D-A system such as the spirobifluorene derivatives, spiro-acridine (ACRFLCN) derivatives, phenoxazine (PXZ) derivatives, carbazolyl dicyanobenzene (CDCB) derivatives, thioxanthone (TX) derivatives. The external quantum efficiency of OLED devices made from these TADF materials was in the range of 4-21% (Nakagawa, Ku, Wong, and Adachi, 2012), (Mehes, Nomura, Zhang, Nakagawa, and Adachi, 2012), (Uoyama, Goushi, Shizu, Nomura, and Adachi, 2012; Wang et al., 2014; X. Wei et al., 2017). Their molecular structures are shown in Figure 3.8.

Figure 3.8 The molecular structures of TADF molecules (**90-103**).

The TADF materials, which containing diphenylsulfone as an acceptor moiety and carbazoyl groups as a donor moiety with the donor-acceptor-donor (D-A-D) system have been reported since 2012 by Adachi et al. Diphenylsulfone (DPS) is widely

studied acceptor in the literature because its electron-withdrawing ability and a twist angle in the center with tetrahedral geometry structure, which limits the conjugation of the compounds, provides promising features for TADF material. The first pure blue emission with a diphenylsulfone derivatives was reported. The structure of DPA-DPS (**104**), DTPA-DPS (**105**), and DTC-DPS (**106**) were containing two arylamine derivatives as donor moieties and diphenylsulfone as an acceptor. Their structures are shown in Figure 3.9 (Q. Zhang et al., 2012). The OLED devices based on these compounds exhibited a very high external quantum efficiency (EQE) of nearly 10% at low current density with bright pure blue emission. The studies reveal that (**104**), DTPA-DPS (**105**), and DTC-DPS (**106**) display small ΔE_{ST} values of 0.54, 0.45, and 0.32 eV, respectively. Owing to the *tert*-butyl group on the diphenylamine unit enhances the electron-donating ability leads to lowers the CT energy and the ΔE_{ST} . Moreover, the replacement of a diphenylamine unit with a carbazole unit slightly raises the 1CT state, and raises the $^3\pi\pi^*$ state, resulting in a further decrease in its ΔE_{ST} .

Figure 3.9 The molecular structures of diphenyl sulfoxide derivatives.

The concept to reduce the ΔE_{ST} is to enhance the electron-donating ability of the donor moieties by added the *tert*-butyl group into the molecules, so the more electron-rich methoxy groups were used to replace the *tert*-butyl substituents on the carbazole

donors. The deep blue TADF material, *bis*[4-(3,6-dimethoxycarbazole)phenyl]sulfone (DMOC-DPS (**107**)) has been synthesized. The results reveal that significantly decreases the ΔE_{ST} from 0.32 eV for DTC-DPS (**105**) to 0.21 eV for DMOC-DPS (**107**) in a doped film. The OLED device exhibited a turn-on voltage at 4.0 V, a maximum EQE of 14.5%, CIE coordinate of (0.16, 0.16). The molecular structures of DTC-DPS (**29**) and DMOC-DPS (**107**), HOMO and LUMO distribution of DMOC-DPS (**107**) is depicted in Figure 3.10 (Wu et al., 2014).

Figure 3.10 The molecular structures of DTC-DPS (**106**) and DMOC-DPS (**107**), and their HOMO and LUMO distribution.

After that, the blue OLED containing a 9,10-dihydroacridine/diphenylsulfone derivative have been designed and synthesized. The OLED devices were fabricated and revealed a high external quantum efficiency of 19.5% and reduced efficiency roll-off characteristics at high luminance. The molecules were designed as charge transfer (CT)

molecules with the D-A type molecules and D-A-D-type molecules. D-A type molecules consist of 5-phenyl-5,10-dihydrophenazine (PPZ) as a donor unit and different acceptor units of 2,5-diphenyl-1,3,4-oxadiazole (DPO) and 3,4,5-triphenyl-1,2,4-triazole (TPT). Moreover, the D-A-D-type molecules consist of diphenylsulphone (DPS) as an acceptor and different donor units of PPZ, phenoxazine (PXZ) and 9,9-dimethyl-9,10-dihydroacridine (DMAC). The results revealed that the large twisted intramolecular charge transfer molecules can emit an efficient and short lifetime when the emission peak energy is high enough and the lowest locally excited triplet state (^3LE) state is higher than the ^3CT state. The molecular structures of all compounds are presented in Figure 3.11 (Q. Zhang et al., 2014).

Figure 3.11 The molecular structures of the investigated compounds.

Divinyl sulfides and sulfones derivatives with the D- π -A system have been synthesized by using a Wittig-Horner reaction. The intramolecular charge transfer (ICT) occurs from the combination of the electron from the carbazole moiety (D) and sulfone acceptor (A) which connected by a π -linker leads to obtaining a large Stokes'

shift, which behaves like a “push-pull” architecture. Owing to the D- π -A- π -D structure of these materials separated the charge in the ground and excited-state provides them with unique optical and electrical properties. These novel molecules represent an efficient alternative as stable non-heterocyclic π -conjugated compounds for potential applications as photoactive or two-photon absorption chromophores. The molecular structures of all compounds are presented in Figure 3.12 (Monçalves, Rampon, Schneider, Rodembusch, and Silveira, 2014).

Figure 3.12 The molecular structures of the desired compounds (114-119).

Novel TADF emitters containing diphenylsulphone (DPS) as an electron acceptor and spiro[acridine-9,90-fluorene] (ACFL) and spiro[acridine-9,90-xanthene] (ACXA) as electron donors have been reported. Their electronic and optical properties were investigated theoretically for an OLED. The calculated ΔE_{ST} values of ACFL-DPS and ACXA-DPS of 0.012 and 0.014 eV, respectively. The OLED device based on ACXA-

DPS as emitter showed a small ΔE_{ST} with an emission wavelength of 2.802 eV (442 nm). Their molecular structures are presented in Figure 3.13 (Lee and Kim, 2016a).

Figure 3.13 The molecular structures of DPS derivatives.

The novel TADF was designed and synthesized by replaced the methoxy group of DMOC-DPS to tetra-methyl in the 1, 3, 6, and 8 positions of carbazoyl group in order to enhance the TADF efficiency. The results revealed that the calculated ΔE_{ST} of TMC-DPS (**122**) (0.094 eV) was smaller than DMOC-DPS (**107**) (0.386 eV) due to the two methyl groups in the 1,8 positions of carbazole ring working to maintain a large dihedral angle through steric repulsion. Both materials showed an emission wavelength of 439.9 nm (2.82 eV), but TMC-DPS (**122**) exhibited the TADF OLED character because of its small ΔE_{ST} and large dihedral angle. The chemical structures and the schematic energy diagram of these materials are shown in Figure 3.14 (Lee and Kim, 2016b).

Figure 3.14 The chemical structures and the schematic energy diagram of DMOC-DPS (107) and TMC-DPS (122).

The blue TADF materials for OLED which containing of *bis*(phenylsulfonyl) benzenes (BPSBs) as acceptor core and the different donor were reported. The introduction of alkyl groups or *ortho*-substituted and thus twisted, sterically demanding diphenylamine donors in order to increase the solubility of these compounds. Solution-processed OLEDs were fabricated by using these compounds as an emitter in the EML lead to deep blue emission from 466 to 436 nm with a low CIE_y value of 0.08, reach brightnesses of 10000 cd/m^2 , and also show efficiencies of 1000 cd/m^2 . The chemical structures of these materials are shown in Figure 3.15 (Jürgensen et al., 2017).

Figure 3.15 The chemical structures of the BPSB derivatives (123-127).

TADF materials containing dipyridylsulfone core as the electron-accepting unit and di-tert-butyl carbazoles as electron-donating units, *p*DTCz-2DPyS (**128**) and *p*DTCz-3DPyS (**129**) have been reported. Both emitters show blue emission in the range of 450–465 nm with a similar ΔE_{ST} (0.22 eV for *p*DTCz-3DPyS (**129**) and 0.21 eV and *p*DTCz-2DPyS (**128**)). The delayed emission of *p*DTCz-2DPyS (**128**) is higher than *p*DTCz-3DPyS (**129**). In the doped films, *p*DTCz-2DPyS (**128**) exhibited photoluminescence quantum yields of 60%. The EQE of *p*DTCz-2DPyS (**128**) and *p*DTCz-3DPyS (**129**) when doped in *bis*[2-(diphenylphosphino) phenyl]ether oxide (DPEPO) was 13.4% and 11.4%, respectively, which is higher than the reference *p*DTCz-DPS (4.6%). Moreover, *p*DTCz-3DPyS (**129**) shows pure blue electroluminescence with CIE color coordinates of (0.15, 0.12) compared to *p*DTCz-2DPyS (**128**) with coordinates of (0.15, 0.19). The molecular structure of *p*DTCz-2DPyS (**128**) and *p*DTCz-3DPyS (**129**) are shown in Figure 3.16.

Figure 3.16 The molecular structures of *p*DTCz-2DPyS (**128**) and *p*DTCz-3DPyS (**129**).

The thermally activated delayed fluorescence (TADF) emitters are extensively developed because of their potential as high-efficiency emitter with near 100% internal quantum efficiency for high performance organic light-emitting diodes. From the above review, there are several strategies to design and synthesized TADF materials to

improve the performance and efficiency of OLED devices base on these compounds. The one concept is used D- π -A- π -D system which behaves like a “push-pull” architecture to obtain a small ΔE_{ST} and separated The HOMO and LUMO. In this chapter, novel TADF emitters based on D- π -A- π -D system of *bis*(4-carbazolephenyl) sulfone were designed and synthesized which compose of carbazole derivatives as the donor, benzene as the π -linker, and sulfone as the acceptor. The effect of electron-donating ability on TADF property was investigated by varying the donor moieties which linked on the phenyl π -linker. The effect of free rotation of π -linker on TADF property was investigated by a varying number of phenyl substituents on the π -linker. The photophysical, electrochemical, and delayed fluorescence properties of these materials were characterized by UV-vis, CV, and time-resolved fluorescence spectroscopic analyses.

3.2 Research objectives

3.2.1 To design, synthesize and characterize TADF materials for OLED as shown in Figure 3.17.

3.2.2 To study the photophysical, electrochemical, and thermal properties by using UV-Visible spectroscopy, fluorescence spectroscopy, cyclic voltammetry, and DSC-TGA techniques.

Figure 3.17 The molecular structures of the desired TADF molecules **4-13**.

3.3 Synthesis of TADF emitters

3.3.1 Synthetic approach

The desired TADF emitters should be obtained by bromination of *bis*(4-fluorophenyl) sulfone to afford dibromo- or tetrabromo sulfone followed by Suzuki cross-coupling reaction of dibromo- or tetrabromo sulfone with phenylboronic acid to afford the key intermediate which composed of diphenyl or tetraphenyl substituted on phenyl linker. Finally, the nucleophilic substitution of key intermediate with carbazole donor derivatives and after purification by chromatography and recrystallization, the desired TADF compounds should be obtained as outlined in Figure 3.18.

Figure 3.18 Synthetic approach to the synthesis of the TADF molecules.

3.3.2 The synthesis of **131** and **132**

The bromo di-substituted and tetra-substituted compounds **131** and **132** was synthesized via bromination of *bis*(4-fluorophenyl) sulfone (**130**) using *N*-bromo succinimide in sulfuric acid at room temperature and heated at 70°C to afford **131** and **132** in a moderate yield of 44% and 46%, respectively, as shown in Figure 3.19.

Figure 3.19 The synthesis of dibromo-substituted (**131**) and tetrabromo-substituted (**132**) sulfone.

3.3.3 The synthesis of key intermediates **133** and **134**

The key intermediates were used as the starting materials for the final step to the synthesis of TADF emitters, which could be synthesized on a milligram scale starting from the dibromo-substituted (**133**) and tetrabromo-substituted (**134**) sulfone using Suzuki cross-coupling reaction as outlined in Figure 3.20.

Figure 3.20 The synthesis of key intermediates **133** and **134**.

Suzuki coupling is a palladium-catalyzed cross-coupling reaction of organoboranes with organic halides. The first step was the oxidative addition of palladium (0) to the organic halide starting material (**131**) to form the organopalladium species. The second step was metathetic exchange with base gives intermediate, which via transmetalation with the phenylboronic acid forms the organopalladium species. Finally, reductive elimination of the desired product (**133**) restores the original palladium catalyst (0) as shown in Figure 3.21.

Figure 3.21 The mechanism of the Suzuki reaction.

The dibromo-DPS (**131**) and tetrabromo-DPS (**132**) were reacted with phenylboronic acid in the presence of sodium carbonate as base via Suzuki reaction to give key intermediates **133** and **134** in a good yield of 82% and 58%, respectively.

3.3.4 The synthesis of carbazole donor **136** and **138**

The carbazole donor **136** and **138** could be synthesized on a gram scale starting from the 3,6-diiodo carbazole (**135**) and 2,7-dibromo carbazole (**136**) using the Suzuki cross-coupling reaction as outlined in Figure 3.22.

Figure 3.22 The synthesis of key intermediates **136** and **138**.

The 3,6-diiodo carbazole (**135**) and 2,7-dibromo carbazole (**137**) were reacted with phenylboronic acid in the presence of sodium carbonate as base via Suzuki reaction to give 3,6-diphenyl carbazole (**136**) and 2,7-diphenyl carbazole (**138**) in a moderate yield of 42% and 65%, respectively.

3.3.5 The synthesis of TADF emitters (4-13)

Finally, Nucleophilic substitution of key intermediates **133** and **134** with carbazole derivatives (**136**, **138**, Cz (**139**), G1 (**73**), and G2 (**74**)) using sodium hydride in dimethylformamide afforded the desired molecules, DPS1-DPS10 in a yield of 9-94%. Their structures were confirmed by ^1H NMR, ^{13}C NMR, and HRMS spectrometric methods. The synthetic procedure of the TADF emitters (**4-13**) is shown in Figure 3.23.

Figure 3.23 The synthesis of the TADF emitters **4-13**.

The structure of CzDPS (**4**) was confirmed by ^1H -NMR spectroscopy. The ^1H -NMR spectrum showed doublet of the para position of phenyl linker at $\delta = 8.27$ (4H) and 7.84 (4H) ppm with the coupling constant (J) of 8.4 Hz. The carbazole protons produce doublet signals at 8.14 (4H) and 7.50 (4H) ppm with the J of 7.4 Hz, another proton showed signals at $\delta = 7.43$ (4H, t), 7.33 (4H, t) ppm. The ^{13}C -NMR spectrum showed the chemical shift of carbon signals in the range of 142.8-109.6 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 548.1002 (required $m/z = 548.1558$).

The ^1H -NMR spectrum of G1DPS (**5**) showed doublet of the para position of phenyl linker at $\delta = 8.23$ (4H) and 7.82 (4H) ppm with the coupling constant (J) of 8.4 Hz. The carbazole protons produce singlet signals at 8.13 (4H) and another proton showed multiplet signals at $\delta = 7.49$ -7.43 (8H) ppm. The protons of *tert*-butyl group of G₁ showed the singlet signal at 1.46 (36H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 144.1-109.2 ppm and the alkyl carbon at 34.8 and 31.9 ppm. Moreover, HRMS of the compound with $m/z = 772.3282$ (required $m/z = 772.4062$).

The ^1H -NMR spectrum of 3,6-diPhCz-DPS (**6**) showed doublet of the para position of phenyl linker at $\delta = 8.33$ (4H) and 7.90 (4H) ppm with the coupling constant (J) of 8.4 Hz. The carbazole protons produce singlet signals at 8.39 (4H), while another proton of carbazole and phenyl showed multiplet signals at $\delta = 7.70$ (12 H, m), 7.58 (4H, d, $J = 8.4$ Hz), 7.49 (8H, t), 7.37 (4H, t) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 142.7-108.2 ppm. Moreover, HRMS of the compound with $m/z = 853.1968$ (required $m/z = 853.2844$).

The ^1H -NMR spectrum of 2,7-diPhCz-DPS (**7**) showed doublet of the para position of phenyl linker at $\delta = 8.33$ (4H) and 7.91 (4H) ppm with the coupling constant (J) of 8.4 Hz. The carbazole protons produce singlet signals at 7.66 (4H) ppm, while another proton of carbazole produces doublet signals at $\delta = 8.19$ (4H) and 7.58 (4H). Phenyl protons showed the multiplet signals at $\delta = 7.63$ (8H), 7.42 (8H), and 7.34 (4H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 142.7-110.1 ppm. Moreover, HRMS of the compound with $m/z = 852.7777$ (required $m/z = 853.2844$).

The ^1H -NMR spectrum of G1-2Ph-DPS (**8**) showed singlet protons of the phenyl linker at $\delta = 8.35$ (2H) and doublet protons of ortho position at 8.15 (2H) and 7.69 (2H) ppm. The carbazole protons produce singlet signals at 8.02 (4H, s) and another proton showed multiplet signals at $\delta = 7.30$ -6.97 (18H) ppm. The protons of *tert*-butyl group of G₁ showed the singlet signal at 1.40 (36H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 143.2-109.4 ppm and the alkyl carbon at 34.7 and 31.9 ppm. Moreover, HRMS of the compound with $m/z = 924.4772$ (required $m/z = 924.4688$).

The ^1H -NMR spectrum of G2-2Ph-DPS (**9**) showed singlet protons of the phenyl linker at $\delta = 8.39$ (2H) and doublet protons of ortho position at 8.12 (2H) and 7.69 (2H) ppm. The carbazole protons produce singlet signals at 8.03 (4H, s) and another proton showed multiplet signals at $\delta = 7.47$ -7.17 (18H) ppm. The protons of *tert*-butyl group of G₁ showed the singlet signal at 1.44 (72H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 142.7-109.0 ppm and the alkyl carbon at 34.7 and 32.0 ppm. Moreover, HRMS of the compound with $m/z = 1809.1216$ (required $m/z = 1808.9506$).

The ^1H -NMR spectrum of G1-4Ph-DPS (**10**) showed singlet protons of the phenyl linker at $\delta = 8.27$ (4H) ppm. The carbazole protons produce singlet signals at $\delta = 7.85$ (4H) and another proton showed multiplet signals at $\delta = 7.16$ - 6.77 (28H) ppm. The protons of *tert*-butyl group of G₁ showed the singlet signal at $\delta = 1.34$ (36H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 143.3-108.6 ppm and the alkyl carbon at 34.7 and 32.0 ppm. Moreover, HRMS of the compound with $m/z = 1076.5097$ (required $m/z = 1076.5315$).

The ^1H -NMR spectrum of G2-4Ph-DPS (**11**) showed singlet protons of the phenyl linker at $\delta = 8.45$ (4H). The carbazole protons produce singlet signals at $\delta = 7.96$ (4H), the second generation of dendron produce singlet signals at $\delta = 8.11$ (8H), and another proton showed multiplet signals at $\delta = 7.42$ - 7.14 (44H) ppm. The protons of *tert*-butyl group of G₂ showed the singlet signal at $\delta = 1.40$ (72H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 144.4-109.0 ppm and the alkyl carbon at 34.7 and 32.0 ppm. Moreover, HRMS of the compound with $m/z = 1961.3507$ (required $m/z = 1961.0132$).

The ^1H -NMR spectrum of 3,6-diPhCz-4Ph-DPS (**12**) showed singlet signals of phenyl linker at $\delta = 8.36$ (4H) ppm. The carbazole protons produce singlet signals at $\delta = 8.16$ (4H), while another proton of carbazole and phenyl showed multiplet signals at $\delta = 7.64$ (8H), 7.44 (12H), 7.30 (4H), 7.03 (24H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 144.1-108.8 ppm. Moreover, HRMS of the compound with $m/z = 1157.2931$ (required $m/z = 1157.4096$).

The ^1H -NMR spectrum of 2,7-diPhCz-4Ph-DPS (**13**) showed singlet signals of phenyl linker at $\delta = 8.22$ (4H) ppm. The carbazole protons produce singlet

signals at $\delta = 8.04$ (4H), while another proton of carbazole and phenyl showed multiplet signals at $\delta = 7.92$ (4H), 7.58 (8H), 7.51 (16H), 7.47 (16H), 7.42 (16H), 7.31 (16H), 7.01 (20H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of aryl carbon signals in the range of 144.4-110.4 ppm. Moreover, HRMS of the compound with $m/z = 1157.2896$ (required $m/z = 1157.4096$).

3.4 Results and discussion

3.4.1 Optical properties

The UV-vis absorption and fluorescence spectra of the TADF emitters were investigated in dilute toluene solution (10^{-5} - 10^{-6} M) and the neat film by UV-vis and photoluminescence spectroscopies as shown in Figure 3.24. All TADF (**4-13**) compounds showed two broad and structureless absorption bands, an absorption band around 290 nm corresponding to the π - π^* transition of the carbazole moieties and an absorption band with a maximum at 340 nm assigned to the n - π^* transition leads to occur intramolecular charge-transfer (ICT). All the TADF emitters showed a similar absorption band in solution and in the neat film. CzDPS (**4**) and G1DPS (**5**) exhibited strong occur ICT bands with a maximum at 340 nm and high molar absorptivity (ϵ). In addition, G1-2Ph-DPS (**8**), G2-2Ph-DPS (**9**), G1-4Ph-DPS (**10**), G2-4Ph-DPS (**11**), 3,6-diPhCz-DPS (**6**), and 3,6-diPhCz-4Ph-DPS (**12**) revealed the ICT band appears as a shoulder below the π - π^* absorption peak with a slightly red-shifted at 344 nm indicating that there are charge transfer from the LUMO of the acceptor moieties to the HOMO of the carbazole donor moieties like a push-pull system and the spatial overlap due to the twist angle between DPS core and the carbazole derivatives. The small

bathochromic effect implied that the intermolecular interactions could be effectively prevented due to the bulky carbazole dendrons. In the other hand, the absorption bands of 2,7-diPhCz-DPS (**7**) and 2,7-diPhCz-4Ph-DPS (**13**) showed a slightly blue-shifted with a maximum at 320 nm, which indicates that the C-C bonds of π -linker of these molecules were restricted due to the steric hindrance from the phenyl groups at the 2 and 7 positions of carbazole donor moieties. Besides that, the ICT character of the molecules remained with the increase of the phenyl group. The fluorescence spectra of TADF emitters exhibited emission bands with a maximum of around 370-455 nm in toluene. The fluorescence spectra in neat films are identical to those in toluene. 2,7-diPhCz-DPS (**7**) and 2,7-diPhCz-4Ph-DPS (**13**) revealed a deep blue emission band at around 370 nm, while G2-2Ph-DPS (**9**) and G2-4Ph-DPS (**11**) showed sky blue emission with the longest wavelength at 455 nm because of their donor moieties which containing the second generation of 3,6-di-*tert*-butylcarbazole, G2. The photophysical data of TADF emitters were listed in Table 3.1. The energy gap (E_g^{opt}) of all TADF materials which calculated from the onset wavelength of absorption spectra were in the range of 3.04-3.39 (eV). All TADF emitters exhibited the singlet state (S_1) which calculated from the onset of the fluorescence spectra in the range of 3.03-3.51 (eV). In the case of the dendron group, the singlet state (S_1) of G1DPS (**5**), G1-2Ph-DPS (**8**), G2-2Ph-DPS (**9**), G1-4Ph-DPS (**10**), and G2-4Ph-DPS (**11**) was decreased when the dendron generation increase indicating that by attaching higher generation carbazoles via their *N*-position to the 3,6-positions of the inner carbazole moiety influence on the singlet energy of the whole molecule.

Figure 3.24 UV-vis absorption of TADF emitters in (a) dilute solution in toluene (10^{-5} M) (b) solid film and fluorescence spectra in (c) dilute solution in toluene (10^{-6} M) and (d) solid film.

3.4.2 Commission International de l'Eclairage (CIE)

The color perceived by the human eye in full daylight by sensors on the retina, called cones. Cones are divided into three types by the sensitivity from the light of cones, they are short (S, 420-440 nm), middle (M, 530-540 nm), and long (L, 560-580 nm) wavelengths which can be assigned to blue, green, and red, respectively. If the light is not bright enough, the cones do not work resulting in vision without color, so the human eyes perceived colors only in the range of 10^{-2} to 10^5 cd/m². Therefore, the CIE chromaticity diagram is used to describe the color perceived by eye because color

perception differs from person to person. Chromaticity diagram and CIE_{xy} values of all TADF emitters in dilute toluene solution and in the neat film are shown in Figure 3.25 and summarized in Table 3.2. The results revealed that G2-2Ph-DPS (**9**) and G24Ph-DPS (**11**) exhibited the high x,y coordinate with blue emission. It might be from the electron move from the second generation of dendron moieties to the center acceptor like a push-pull interaction induce a red-shifted in the emission spectrum. On the other hand, 2,7-diPhCz-DPS (**7**) and 2,7-diPhCz-4Ph-DPS (**13**) showed the deep blue emission with the lowest CIE_{xy} values of (0.163, 0.030) and (0.160, 0.038), when compared to the standard blue (0.14, 0.08).

Table 3.2 CIE(x,y) coordinates of TADF emitters.

Compounds	CIE ^{sol} (x,y)	CIE ^{film} (x,y)
CzDPS	(0.161, 0.029)	(0.160, 0.061)
G1DPS	(0.159, 0.038)	(0.162, 0.093)

3.4.3 Emission decays

To further demonstrate the character of TADF occurred in the solution state, the emission decays of these TADF compounds were investigated in dilute toluene solution (10^{-6} M) under argon and oxygen atmosphere. In order to prevent the oxygen quenching of triplet state, argon gas has been used to replaced oxygen gas by using a freeze-thaw cycle, which is consists of quickly freezing at -195°C in liquid nitrogen and thawing at room temperature in sequence (the tubes could be thawed quickly at $6-10^{\circ}\text{C}$ in a water bath for 10 min and kept at room temperature). Then argon gas has been flushed into the tube and repeats freeze-thaw cycles for three times. The transient PL decay of all emitters displayed two components, the first component is a fast decay which can be assigned to prompt fluorescence which arising from $S_1 \rightarrow S_0$ transition and the second component is a slower one which can be assigned to delayed fluorescence which arising from repopulation of the S_1 through RISC from the T_1 followed by $S_1 \rightarrow S_0$ transition. The lifetimes of prompt and delayed fluorescence were summarized in Table 3.3. The lifetimes were estimated to be 4-19 ns for prompt

fluorescence and 36-600 ns for delayed fluorescence under the argon atmosphere. The emission decay of all TADF **4-13** in toluene under argon and oxygen atmosphere at room temperature are shown in Figure 3.26.

Table 3.3 The lifetimes of prompt and delayed fluorescence of TADF emitters.

3.4.4 Oxygen quenching of the photoluminescence quantum yield

Thermally activated delayed fluorescence involves reverse intersystem crossing (RISC) from triplet state (T_1) to singlet state (S_1) followed by a fluorescent transition from $S_1 \rightarrow S_0$ and emit light. The intensity of the emission depends on the mechanism that removes the excitons from T_1 . However, TADF emission has been quenched by oxygen molecule (O_2) because it has a triplet ground state and repopulation of the T_1 state via energy transfer. Therefore, the TADF character can be checked by measurement of the photoluminescence quantum yield in the absence and presence of oxygen. The photoluminescence quantum yields were measured using the direct method with the integrating sphere module. The quantum yield of the non-degassed solution was measured using the integrating sphere module and the degassed solution extrapolated based on the relative intensity of the emission. The change in emission intensity when all TADF solution **4-13** are exposed to oxygen are shown in Figure 3.27. The photoluminescence quantum yield of all TADF emitters **4-13** in the

toluene solution exhibited enhancement under Argon atmosphere, suggests that the T_1 state is involved in the emission process and can be concluded that the reduction in quantum yield is the first indicator that the emission could contain TADF.

Figure 3.27 Emission spectra of all TADF materials **4-13** in degassed solution (black) and non-degassed solution (red) in toluene (10^{-5} M).

The degassed quantum yield of G1DPS (**5**) which is calculated based on the relative intensity of the emission and measured by the integrating sphere module has been investigated. In the first attempt, the solution has been degassed by flushed argon gas into the solution for 1 hour. The quantum yield of degassed and non-degassed solutions was measured using FLS-980 fluorescence spectrometer via the integrating sphere module. The quantum yield value of measurement was determined to be 61%. The ratio of the emission decay from the argon bubbles method was calculated to be 1.21 and the quantum yield was estimated to be 66%. In addition, the quantum yield of

G1DPS (**5**) from these two methods shows almost the same value which indicated that quantum yield of degassed can be estimated from the relative intensity of the emission decay as shown in Figure 3.28(a). Moreover, the emission decay of the G1DPS (**5**) solution which using the freeze-thaw method has been measured by using the FLS-980 fluorescence spectrometer. The relative intensity ratio of the emission was calculated to be 1.23, which is near the ratio from the argon bubbles method as shown in Figure 3.28(b). However, the freeze-thaw method is the most effective and acceptable method for degassing of the solution.

Figure 3.28 The quantum yield of G1DPS (**5**) in degassed solution (black) and non-degassed solution (red) by using argon bubbles method (a) and freeze-thaw method (b).

The fluorescence quantum yield of a non-degassed solution and degassed solution of G1DPS (**5**), G1-2PhDPS (**8**), and G1-4PhDPS (**10**) are summarized in table 3.3. The results revealed that G1DPS (**5**) has the highest yield, while G1-4PhDPS (**10**) shows the lowest yield which might be from the steric hindrance of phenyl groups linked on π -linker restricted free rotation of C-N bond of carbazole donor group. The number of phenyl group increase the quantum yield decrease.

Table 3.4 The fluorescence quantum yield of the non-degassed solution and degassed solution of G1DPS (**5**), G1-2PhDPS (**8**), and G1-4PhDPS (**10**).

G1DPS (5)	54	61
G1-2Ph-DPS (8)	45	53
G1-4Ph-DPS (10)	19	21

3.4.5 Time-Resolved Emission Spectrum (TRES)

The time-resolved emission spectrum (TRES) is a method for approving the origin of the delayed component is delayed fluorescence or phosphorescence by comparing the spectral shape of the prompt and delayed components. In a TRES measurement, a three-dimensional time-resolved spectrum is built up from the emission decay which is measured as a function of emission wavelength. Then the TRES data can be sliced to a snapshot of the emission spectrum at a specified time after the laser flash. The prompt component is a shorter snapshot than the delayed component. If they are identical can be concluded that the delayed component is originated from the fluorescence. As shown in Figure 3.29, the prompt fluorescence of G1-2Ph-DPS (**8**) (red line) and the delayed emission at 30-110 nanoseconds are identical. Therefore, this compound exhibited the TADF characteristic and can be concluded that this strategy for designed TADF molecules is an effective method to achieve efficient TADF.

Figure 3.29 Time-resolved emission spectrum (TRES) of the prompt and delayed fluorescence of degassed G1-2Ph-DPS (**8**) solution.

3.4.6 Solvatochromic behaviors

Normally, the D-A molecules which containing π - π^* transition presented the solvatochromism in their absorption spectra due to the high polarization of the ground-state molecular structure. The changing in the polarity of the solvent leads to the bathochromic shift or hypsochromic in the absorption spectra. Usually, the more polar solvent species polarizes molecules with a higher static dipole moment more strongly, but in some molecules, with a symmetrical structure the static dipole moment of the whole system is equal to zero due to some group were restrict, so these molecules should not display the solvatochromism in the absorption spectra. However, if the excited state of these molecules corresponds to the CT $\pi\pi^*$ -state with the twisted structure and the dipole moment is not equal to zero, the solvatochromic behavior should be observed in the emission spectra rather than in absorption spectra. In order to study the solvatochromic behavior of all TADF compounds **4-13**, various solvents with different polarities such as toluene, chloroform, dichlorobenzene, tetrahydrofuran, and acetonitrile were selected. The UV-vis and emission spectra of all compounds have

been measured. The results revealed that only emission spectra could be observed the bathochromic shifted in polar solvent due to their ICT behavior. The absorption spectra and emission spectra of all TADF emitters **4-13** in different solvents are shown in Figure 3.30.

Figure 3.30 UV-vis absorption and fluorescence spectra of TADF emitters **4-13** in various solvent.

Normally, as the solvent polarity parameter (Δf) based on the Lipper-Mataga equation increases, the stokes shift also increases with a linear correlation. The plots of stokes shift versus solvent polarity parameter (Δf) of all compounds **4-13** were shown in Figure 3.31. The results revealed that the fluorescent properties of all compounds are strongly related to the solvent polarity which might be from the formation of large charge separation due to the twisted structure and high dipole moment in the excited state.

Figure 3.31 The plots of stokes shift versus solvent polarity parameter (Δf) of all TADF compounds **4-13**.

3.4.7 Electrochemical properties

The electrochemical characteristics of the TADF emitters were measured by cyclic voltammetry. All compounds exhibited reversible oxidation processes upon the anodic sweep as shown in Figure 3.32. The first oxidation process assigns to the removal of electrons from the carbazole donor, resulting in radical cations. The HOMO levels of all compounds determined from the onsets of the oxidation potentials were in the range of -5.80 to -5.04 eV, which are similar to the HOMO values from AC2 method and close to the work function of a commonly used indium tin oxide (ITO) anode

(-4.80 eV). The LUMO levels determined from the onsets of the reduction potentials except for G1DPS (**5**), G1-2Ph-DPS (**8**), and G1-4Ph-DPS (**10**) have no reduction signal thus the LUMO levels of these emitters were calculated from the HOMO levels and the corresponding optical bandgaps (E_g^{opt}). The LUMO levels were in the range of -3.81 to -2.46 eV. Electrochemical band gaps (E_g^{ele}) determined using the onsets of the oxidation potentials subtracts by the onsets of the reduction potentials were in the range of 1.29-2.13 eV. The electrochemical data are summarized in Table 3.5.

3.4.8 Thermal properties

The thermal properties of TADF emitters **4-13** were determined by differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA). TGAs reveal that their decomposition temperatures at 5 % weight loss (T_{5d}) are above 400°C, indicating the high thermal stability. The thermogram of TADF materials is shown in Figure 3.33 and the data are listed in Table 3.6.

Figure 3.33 TGA thermograms of TADF emitters **4-13** measured at a heating rate of $10^{\circ}\text{C min}^{-1}$ under N_2 flow.

DSCs (1st and 2nd heating scans) of the TADF emitters reveal a distinct glass transition temperature (T_g) in the range of 175-246 $^{\circ}\text{C}$ as shown in Figure 3.34 and listed in table 3.6. The peak of crystallization and melting could not be observed at higher temperatures, indicating an excellent amorphous glass state stability. The high T_g of all

compounds may be attributed from the rigid structure due to the phenyl substituent on the π -linker induce increasing of the efficiency of the device because an amorphous thin-film device is made from the materials with high T_g is less vulnerable to heat. Therefore, organic materials with high T_g are therefore highly desirable for applications in long lifetime electroluminescent devices.

Figure 3.34 DSC 1st heating (solid line) and 2nd heating (dotted line) scans of TADF emitters 4-13.

3.5 Conclusion

In summary, novel TADF emitters based on D- π -A- π -D system of *bis*(4-carbazolephenyl) sulfone have been successful to synthesized. The molecular structures are composed of carbazole derivatives as the donor, benzene as the π -linker, and sulfone as the acceptor. All TADF emitters exhibited deep blue emission with the strong ICT and showed a slight red shift when changing the donor moieties to a more strongly electron-donating group. Moreover, the twisted molecule with a varying number of phenyl substituents on the π -linker leads to less quantum yield due to the energy loss from the rotation of molecules. Besides that, all compounds revealed the TADF characteristic. We believe that our results could provide a useful guide to design the highly efficient TADF emitter with the twisted molecule to be suitable for applications in OLEDs devices.

CHAPTER IV

THE SYNTHESIS AND CHARACTERIZATION OF THERMALLY ACTIVATED DELAYED FLUORESCENCE DENDRIMERS FOR ORGANIC LIGHT-EMITTING DIODES

4.1 Introduction

As mentioned in Chapter III, an efficient thermally activated delayed fluorescence material has been designed and synthesized by using D- π -A- π -D system leads to a twisted molecule and spatial distribution between the HOMO of donor and LUMO of the acceptor in order to improve the efficiency of OLED devices. The TADF materials are also divided into small molecules, polymers, and dendrimers. The expected results of the dendritic structure of dendrimers are reduced or eliminate strong intermolecular interactions and aggregation that often lead to excimer formation and reduced emission quantum yields due to π - π -stacking interaction of the linear molecules (Kwon, Alam, and Jenekhe, 2004). The light emission of dendrimers can be tuned by changing the core moieties, their solubility can be adjusted by changing the proper surface groups, and their level of intermolecular interactions can be controlled by the type and generation of the dendrons employed. Therefore, in this chapter, we synthesized and investigated new dendrimers based on TADF materials.

In 2004, three new electron-acceptor and light-emitting conjugated dendrimers, (G1-4Q, **140**), (G1-6Q, **141**), and (G2-12Q, **142**), based on a benzene core, poly(phenylene vinylene) dendrons, and diphenylquinoline peripheral groups have been reported by Kwon et al. All dendrimers exhibited blue emission with the high fluorescence quantum yields in the range of 0.69-0.87 and fluorescence lifetimes in the range of 1.4-1.6 ns (Figure 4.1).

Blue TADF dendrimers, which composed of pyrene core, 2-(4-*tert*-butylphenyl)-5-(4-biphenyl)-1,3,4-oxadiazole (PBD) and different carbazole group, 3,6-di-*tert*-butyl-9-phenylcarbazole (CAB) for D1 (**143**) and TPA for D2 (**144**) have been synthesized and characterized (Figure 4.2). The results revealed that D1 (**143**) emit a pure blue emission from the pyrene core without ICT character, while D2 displays ICT in highly polar solvents from both pyrene and PBD core. Besides that, the OLED devices gave a pure blue emission with CIE_{xy} of (0.16, 0.12) with a peak current efficiency of 0.21 cd/A and a peak luminance of 2700 cd/m² (G. Zhang et al., 2016).

Figure 4.1 The molecular structure of dendrimers (140-142).

Figure 4.2 Molecular structures of donor-acceptor dendrimers D1 (**143**) and D2 (**144**).

Two new carbazole-dendronized TADF emitters, which consisting of carbazole dendrons and bis(4-(9,9-dimethylacridin-10(9H)-yl)phenyl) methanone (DMAC-BP) as a core, CDE1 (**145**) and CDE2 (**146**) have been synthesized and investigated. They exhibited excellent thermal stability, good solution processability, and an obvious TADF feature. In neat film, their emission peak is blue-shifted with the increasing generation of the carbazole dendrons, indicating that the donor-acceptor feature of CDE2 (**146**) is weaker than that of CDE1 (**145**). The ΔE_{ST} values are 0.11 eV for CDE1 (**145**) and 0.15 eV for CDE2 (**146**), which RISC can easily occur leads to increasing of delayed fluorescence (DF) decay (523 ns for CDE1 (**145**) and 627 ns for CDE2 (**146**)). The non-doped OLED devices were fabricated and exhibited EQE of 13.8%. Their structure is depicted in Figure 4.3 (Y. Li, Xie, Gong, Wu, and Yang, 2016).

Figure 4.3 Chemical structures of DMAC-BP, CDE1 (**145**) and CDE2 (**146**).

In 2017, two new blue TADF dendrimers G2 (**147**) and G3 (**148**), which composed of a diphenylsulfone core have been reported by Li et al. (Figure 4.4). The results revealed these dendrimers exhibited a reduced singlet-triplet energy gap (ΔE_{ST}) with increasing the dendron generation. The efficient triplet-singlet (T_1-S_1) transition processes, excellent thermal and amorphous stabilities, good solution processability, and appropriate HOMO/LUMO energy levels were suitable for used as non-doped

emitting layers for solution-processed OLEDs. The **G2 (147)** device achieved deep-blue light with an emission peak at 428 nm, a CIE coordinate at (0.15, 0.12) and relatively low-efficiency roll-off at high current density (J. Li et al., 2017).

Figure 4.4 The molecular structures of dendrimers G1 (**106**), G2 (**147**), and G3 (**148**).

TADF carbazole dendrimer (^tBuG2TAZ, **149**) doped in a carbazole dendrimer host G3Ph (**150**), G4Ph (**151**) has been used as an emissive layer (EML) in a solution-processed OLED device. ^tBuG2TAZ doped in G3Ph exhibited green emission ($\lambda_{\text{MAX}} = 502 \text{ nm}$) with a maximum external efficiency (EQE_{MAX}) of 16.1% (Albrecht, Matsuoka, Fujita, and Yamamoto, 2018). Their molecular structures are shown in Figure 4.5.

Figure 4.5 The molecular structures of ^tBuG₂TAZ, (149), G₃Ph (150), and G₄Ph (151).

Besides that, Maasoumi et al. reported the synthesis of poly(dendrimer) containing *fac*-(2-phenylpyridyl)iridium(III) core and fluorenyl-carbazole dendrons, which used as the emitter in the solution-processed OLED device and exhibited an external quantum efficiency of >20% (Maasoumi et al., 2018).

In the same period, the dendrimers with bi-function which are TADF and exciplex-forming, G-TCTA and G-mCP have been synthesized. The introduction of exciplex-forming dendrons into a green TADF emissive core by using a non-conjugated alkyl chain in order to achieve a TADF feature with a reducing the driving voltages by eliminating the injection barrier. The results reveal that a nondoped device of G-mCP achieves an extremely low driving voltage of 2.7 V and high power efficiency of 46.6 lm W⁻¹ (Sun et al., 2018).

From the previous work of our group, we success to synthesize the carbazole dendrimers up to the fourth generation and investigate the performance of the OLED

devices. Their molecular structure is shown in Figure 4.6. They showed significantly high T_g , amorphous and stable electrochemical properties, and great potential as solution-processed hole-transporting materials for OLEDs. Alq3-based green devices exhibited high luminance efficiency and CIE coordinates of 4.45 cd A^{-1} and (0.29, 0.53), respectively (Moonsin et al., 2012).

Figure 4.6 Molecular structures of GnCT (**152-155**).

After that, we reported the synthesis of a series of novel red-emitting bis[5-(fluoren-2-yl)thiophen-2-yl]benzothiadiazole-cored dendrimers (**156-158**) containing carbazole dendrons up to the third generation and the investigation of the solution-processed red OLED device fabrication and performance is also reported. Their

molecular structure is shown in Figure 4.7. The end caps carbazole dendrons reduce the crystallization and retain the high emissive ability of a planar fluorescent core in the solid-state as well as improve the thermal stability with high T_g at 283°C . The solution-processed OLEDs was fabricated and exhibited a red emission color with the wavelength in the range of 622–645 nm, with high luminance efficiencies (up to 4.80 cd A^{-1} at 1.2 mA cm^{-2}) and CIE coordinates of (0.65, 0.33), which are close to the pure red color (Prachumrak et al., 2013).

Figure 4.7 Molecular structures of dendrimers (156-158).

Herein, we designed and synthesized the TADF dendrimers by introducing the diphenyl sulfone (DPS) core into the carbazole dendron using a non-conjugated fluorene hexyl as a linker in order to retain the TADF feature and reducing the driving voltages and π - π -stacking interaction of the linear molecules. Their properties were also investigated.

4.2 Research objectives

4.2.1 To design, synthesize and characterize of TADF dendrimers materials as an emitter for OLEDs

4.2.2 To identify the desired molecules by ^1H -NMR, ^{13}C -NMR, and Mass spectroscopy

4.2.3 To study the photophysical, electrochemical, and thermal properties by using UV-Visible spectroscopy, fluorescence spectroscopy, cyclic voltammetry, and DSC-TGA techniques

4.3 Synthetic procedure

4.3.1 Synthetic procedure

The desired TADF dendrimers should be obtained by alkylation of *bis*(4-fluorophenyl) sulfone with 2,7-dibromocarbazole to afford key intermediate and followed by Suzuki cross-coupling reaction with fluorene borolane which obtained from borylation of various Bromo fluorene. After purification by chromatography and recrystallization, the desired products should be obtained as outlined in Figure 4.8.

Figure 4.8 Synthetic approach to the synthesis of the TADF dendrimers.

4.3.2 Preparation of the key intermediate sulfone **160**

N-alkylation of **159** with 2,7-dibromocarbazole in the presence of sodium hydride in dimethyl formamide (DMF) at 100°C for 24 hr provided the corresponding sulfone **160**. After purification by recrystallization in CH₂Cl₂/Methanol the desired product **160** was obtained in 35% overall yield as shown in Figure 4.9.

Figure 4.9 Preparation of the key intermediate sulfone **160**.

4.3.3 Preparation of 2-bromo fluorene **162**

Bromination of **161** with bromine using ferric chloride as Lewis acid in dichloromethane at room temperature to afford 2-bromo fluorene **162**. After purification by column chromatography and recrystallization in CH₂Cl₂/Methanol the desired product **162** was obtained in 24% overall yield as shown in Figure 4.10.

Figure 4.10 Preparation of 2-bromo fluorene **162**.

4.3.4 Preparation of bromo hexyl fluorene **164**

Bromo hexyl fluorene **164** was obtained from alkylation of 2-bromo fluorene **163** with 1,6-dibromohexane in the presence of Tetra-*n*-butylammonium bromide (TBAB) in 50 wt% NaOH at room temperature for 24 hr. After purification by column chromatography, the product **164** was obtained in 66% overall yield, respectively (Figure 4.11).

Figure 4.11 Preparation of Bromo hexyl fluorene **164**.

4.3.5 Preparation of G1hexyl fluorene bromide **165**

G1hexyl fluorene bromide **165** was obtained from the *N*-alkylation of 2-bromo-9,9-*bis*(6-bromohexyl) fluorene **164** with G1 (**73**) in the presence of potassium hydroxide as a base in DMF at room temperature for 12 hr. After purification by column chromatography and recrystallization in CH₂Cl₂/Methanol the desired product **165** was obtained in 89% overall yield as shown in Figure 4.12.

Figure 4.12 Preparation of 2-bromo-9,9-*bis*(6-bromohexyl) fluorene **165**.

4.3.6 Preparation of TPAfluorene bromide **167**

TPAfluorene bromide **167** was obtained from 2-bromo-fluorenone **166** reacted with triphenylamine in methanesulfonic acid. After purification by column chromatography and recrystallization in CH₂Cl₂/Methanol the desired product **167** was obtained in 65% overall yield as shown in Figure 4.13.

Figure 4.13 Preparation of TPAfluorene bromide **167**.

4.3.7 Preparation of fluorene boronates **170** and **172**

The Miyaura borylation reaction enables the synthesis of fluorene boronates **170** and **172** by cross-coupling of bis(pinacolato)diboron (B_2pin_2) with aryl halides (**165** and **167**) using [1,1'-Bis(diphenylphosphino)ferrocene]dichloropalladium(II) palladium as catalyst in the presence of potassium acetate in toluene as shown in Figure 4.14.

Figure 4.14 Preparation of fluorene boronates **170** and **172**.

The [1,1'-Bis(diphenylphosphino)ferrocene]dichloropalladium(II) was activated to palladium(0) followed by the oxidative addition of the aryl halide. Then the formation of an (acetato)palladium(II) complex was achieved and transmetalation with bis(pinacolato)diboron (B_2pin_2) can be attributed to the high reactivity of Pd–O bond which consists of soft acid and a hard base (HSAB concept). Subsequently, reductive elimination of the fluorene boronates **170** and **172** in the yield of 81 and 86%, respectively and takes place along with the catalyst regeneration. The proposed catalytic cycle for the borylation of aryl halides described by Miyaura is shown in Figure 4.15 (Chow et al., 2013).

Figure 4.15 The proposed mechanism for the borylation of aryl halides.

4.3.8 The synthesis of TADF dendrimers 14-16

The fluorene boronates **170-172** were employed as starting materials for the synthesis of TADF dendrimers **14-16** by reacted with key intermediate sulfone **160** according to the Suzuki coupling reaction as shown in Figure 4.16.

Figure 4.16 The synthesis of TADF dendrimers **14-16**.

The TADF dendrimers could be obtained by the Suzuki coupling reaction which the reaction starts with the oxidative addition of palladium (0) to the organic halide starting material to form the organopalladium species. Subsequently, metathetic exchange with base gives intermediate, which via transmetalation with the phenylboronic acid forms the organopalladium species. Finally, reductive elimination of the desired products as mentioned in chapter III. The fluorene boronates **170-172** were reacted with intermediate sulfone **160** in the presence of sodium carbonate as base via Suzuki reaction to give the desired products **14**, **15** and **16** in a moderate yield of 82%, 49, and 58%, respectively. After purification, their structures were confirmed by ^1H NMR, ^{13}C NMR, and HRMS spectrometric methods.

The structure of G1hexylfluorene-DPS (**14**) was confirmed by ^1H -NMR spectroscopy. The ^1H -NMR spectrum showed doublet of the para position of phenyl linker at $\delta = 8.17$ (4H) and 7.63 (4H) ppm with the coupling constant (J) of 8.6 Hz. The carbazole protons produce singlet signals at $\delta = 8.05$ (4H) and multiplet signals at $\delta = 7.69$ (4H) and 7.58 (4H) ppm. The fluorene protons produce multiplet signals at $\delta = 7.70$ (8H), 7.57 (8H) and 7.19 (12H) ppm. The carbazole of the first generation of dendron produces singlet signals at $\delta = 8.04$ (16H) ppm and doublet signal at $\delta = 7.38$ (16H) and 7.11 (16H) ppm. The methylene proton at the near *N*-atom of carbazole position show triplet signal at $\delta = 4.00$ (16H) ppm, the methyl proton of *tert*-butyl group show singlet signal at $\delta = 1.39$ (144H) ppm, and another alkyl proton showed signals at $\delta = 1.96$ (16H), 1.57 (16H), 1.06 (32H), and 0.62 (16H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of carbon signals in the range of $\delta = 151.3$ -107.9 ppm can be assigned as aryl carbon and $\delta = 55.0$ -23.6 ppm can be assigned as alkyl carbon.

Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 4095.5078 (required m/z = 4094.6219).

The structure of octylfluorene-DPS (**15**) was confirmed by ^1H -NMR spectroscopy. The ^1H -NMR spectrum showed doublet of the para position of phenyl linker at δ = 8.-7 (4H) and 8.00 (4H) ppm with the coupling constant (J) of 9.2 Hz. The carbazole protons produce singlet signals at δ = 7.77 (4 H) and doublet signals at δ = 8.23 (4H) and 7.72 (4H) ppm with the coupling constant (J) of 8.1 Hz. The fluorene protons produce multiplet signals at δ = 7.27-7.66 (28H) ppm. The methylene proton at the near position of C-fluorene shows signal at δ = 1.99 (16H) ppm, and another alkyl proton showed signals at δ = 1.18-0.66 (136H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of carbon signals in the range of 151.6-108.2 ppm can be assigned as aryl carbon and 55.2-14.0 ppm can be assigned as alkyl carbon. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 2101.8084 (required m/z = 2101.4079).

The structure of TPAfluorene-DPS (**16**) was confirmed by ^1H -NMR spectroscopy. The ^1H -NMR spectrum showed doublet of the para position of phenyl linker at δ = 8.21 (4H) and 7.86 (4H) ppm with the coupling constant (J) of 8.4 Hz. The carbazole protons produce singlet signals at δ = 7.74 (4 H) and doublet signals at δ = 8.14 (4H) and 7.75 (4H) ppm with the coupling constant (J) of 8.1 Hz. The fluorene protons produce multiplet signals at δ = 7.70-7.40 (28H) ppm. The proton of the triphenylamine group shows a signal at δ = 7.18-6.88 (112H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of carbon signals in the range of 152.4-108.1 ppm can be assigned as aryl carbon. Moreover, High resolution mass spectrometry

confirmed the identity of the compound with m/z (HRMS) = 3149.8115 (required m/z = 3149.2446).

4.4 Results and discussion

4.4.1 Optical properties

The UV-vis absorption and fluorescence spectra of the TADF dendrimer were investigated in dilute toluene solution (10^{-5} - 10^{-6} M) and the neat film by UV-vis and photoluminescence spectroscopies as shown in Figure 4.17. All dendrimers **14-16** exhibited absorption bands around 350 nm corresponding to the π - π^* transition of the carbazole moieties without ICT character for **14** and **15**, while the dendrimer **16** showed the absorption band around 310 nm corresponding to the π - π^* transition with strong ICT character from TPA donor moieties appears as a shoulder below the π - π^* absorption peak. The fluorescence spectra of TADF emitters exhibited blue emission in toluene with a maximum wavelength at 353, 354, and 313 nm for **14**, **15**, and **16**, respectively. The fluorescence spectra in neat films are slightly redshift to those in toluene. The photophysical data of TADF dendrimers were listed in Table 4.1. The energy gap (E_g^{opt}) of all materials which calculated from the onset wavelength of absorption spectra were in the range of 3.18-3.21 (eV). All TADF compounds exhibited the singlet state (S_1) which calculated from the onset of the fluorescence spectra in the range of 3.72-3.75 (eV).

4.4.2 Commission International de l'Eclairage (CIE)

Chromaticity diagram and CIE_{xy} values of all TADF dendrimers in dilute toluene solution and in the neat film are shown in Figure 4.18 and summarized in Table 4.2. The results revealed that all TADF dendrimers **14-16** exhibited the CIE_{xy} values in the blue emission region.

Table 4.2 CIE(x,y) coordinates of TADF dendrimer **14-16**.

4.4.3 Emission decays

As illustrated in chapter III, the TADF characteristic can be confirmed by the emission decay, which measured in dilute toluene solution (10^{-6} M) under argon and oxygen atmosphere. The results revealed that the transient PL decay of all compounds displayed two components, the first component is a fast decay which can be assigned to prompt fluorescence which arising from $S_1 \rightarrow S_0$ transition and the second component is a slower one which can be assigned to delayed fluorescence which arising from repopulation of the S_1 through RISC from the T_1 followed by $S_1 \rightarrow S_0$ transition. The lifetimes of prompt and delayed fluorescence were summarized in Table 4.3. The lifetimes were estimated to be 20-42 ns for prompt fluorescence and 112-302 ns for delayed fluorescence under the argon atmosphere. The emission decay of all TADF **14-16** in toluene under argon and oxygen atmosphere at room temperature are shown in Figure 4.19.

Table 4.3 The lifetimes of prompt and delayed fluorescence of TADF dendrimers **14-16**.

Figure 4.19 The emission decay and fit tail of TADF dendrimers **14-16** in toluene under oxygen and argon atmosphere at room temperature.

4.4.4 Oxygen quenching of the photoluminescence quantum yield

The RISC of TADF emission can be quenched by oxygen molecules (O_2) as mentioned in the previous chapter. Therefore, the TADF character can be checked by measurement of the emission decay in the absence and presence of oxygen. The results revealed that TADF dendrimers **14** and **16** can be observed the change in emission intensity when exposed in argon. On the other hand, TADF dendrimers **15** exhibited identical spectra in both oxygen and argon atmosphere, it might be from the molecule

of **15** has no intramolecular charge transfer due to the donor-acceptor system. The emission spectra of all compounds are shown in Figure 4.20.

Figure 4.20 Emission spectra of all TADF dendrimers **14-16** in degassed solution (black) and non-degassed solution (red) in toluene (10^{-5} M).

4.4.5 Solvatochromic behaviors

In order to investigate the solvatochromic behavior of all TADF dendrimers **14-16**, toluene, chloroform, dichlorobenzene, tetrahydrofuran, and acetonitrile were selected to dissolve the study compounds in UV-vis and fluorescence measurement. The results revealed that both UV-vis and emission spectra of **14** and **15** could not be observed the bathochromic shifted in polar solvent due to the ICT behavior. It could be suggested that non-conjugated donor and acceptor moieties linker by using alkyl chain resulting in their ICT character. On the other hand, the dendrimer **16** exhibited a slightly

bathochromic shifted in polar solvent due to the ICT behavior. The absorption spectra and emission spectra of all TADF **14-16** in different solvents are shown in Figure 4.21.

Figure 4.21 UV-vis absorption and fluorescence spectra of TADF dendrimer **14-16** in various solvent.

Besides that, the solvatochromic behavior can be confirmed by using the plots of stokes shift versus solvent polarity parameter (Δf), if Δf increase, the stokes shift also increases with a linear correlation. The results revealed that only dendrimer **16** displays the relation between optical properties and the polarity of solvent which might be from the conjugation of TPA and fluorene moieties lead to the formation of large charge separation. The plots of stokes shift versus solvent polarity parameter (Δf) of all TADF dendrimers **14-16** are shown in Figure 4.22.

Figure 4.22 The plots of stokes shift versus solvent polarity parameter (Δf) of TADF dendrimers **14-16**.

4.4.6 Electrochemical properties

The electrochemical characteristics of the TADF dendrimers were measured by cyclic voltammetry. All compounds exhibited reversible oxidation processes upon the anodic sweep as shown in Figure 4.23. The first oxidation process assigns to the removal of electrons from the donor, resulting in radical cations. The HOMO levels of all compounds determined from the onsets of the oxidation potentials were in the range of -5.63 to -5.11 eV, which are near to the HOMO values from AC2 method (5.67-5.71 eV). The LUMO levels determined from the onsets of the reduction potentials were in the range of -4.03 to -3.73 eV. Electrochemical band gaps (E_g^{ele}) determined using the onsets of the oxidation potentials subtracts by the onsets of the reduction potentials of TADF dendrimers **14**, **15**, and **16** was 1.90, 1.68, and 1.07 eV, respectively. The electrochemical data are summarized in Table 4.4.

Figure 4.23 CV curves of TADF dendrimers in CH_2Cl_2 solution using 0.1 M Bu_4NPF_6 at a scan rate of 50 mV/s under argon flow.

4.4.7 Thermal properties

The thermal properties of TADF dendrimers **14-16** were determined by differential scanning calorimetry (DSC) and thermogravimetric analysis (TGA). TGAs reveal that their decomposition temperatures (T_{5d}) at 5 wt% weight loss are above 400°C, indicating the high thermal stability. The thermalogram of TADF materials is shown in Figure 4.24 and the data are listed in Table 4.5.

Figure 4.24 TGA thermograms of TADF dendrimers **14-16** measured at a heating rate of 10°C min⁻¹ under N₂ flow.

Table 4.5 Thermal properties of all TADF compounds.

Compounds	T_{5d} (°C)	T_g (°C)
G1hexylfluorene-DPS (14)	432	162
Octylfluorene-DPS (15)	420	77
TPAfluorene-DPS (16)	554	250

DSCs (1st and 2nd heating scans) of G1hexylfluorene (**14**) and TPAfluorene (**16**) reveal a distinct glass transition temperature (T_g) of 167 and 260°C, which might be attributed from the rigid structure due to the G1 dendron or TPA end cap moieties at

the non-conjugated linker indicating a high thermal stability of amorphous state, while octylfluorene (**15**) exhibited a low T_g at 82°C, which arise from alkyl-substituted on the fluorene moieties. Therefore, the high T_g of G1hexylfluorene (**14**) and TPAfluorene (**16**) resulting in the long lifetime of the electroluminescent devices. The DSC scan is shown in Figure 4.25 and listed in table 4.5.

Figure 4.25 DSC 1st heating (solid line) and 2nd heating (dash line) scans of TADF dendrimers **14-16**

4.5 Conclusion

In summary, we have succeeded in synthesizing the TADF dendrimers based on *bis*(4-carbazolephenyl) sulfone as the TADF core. The G1 carbazole and TPA were used as an end-capping group of the fluorene donor moieties and D- π -A- π -D system of the desired molecule was also retaining. All TADF dendrimers can be dissolved in an organic solvent and exhibited blue emission with strong fluorescence intensity, but only TPAfluorene-DPS **16** reveals the ICT characteristic. Their dendritic structure, which arises from G1 and TPA moieties leads to increased T_g resulting in the thermal property of these materials. We believe that our results could provide a useful guide to design the highly efficient TADF dendrimer to be suitable for applications in OLEDs devices.

CHAPTER V

THE SYNTHESIS AND CHARACTERIZATION OF AGGREGATION-INDUCED EMISSION MATERIALS FOR ORGANIC LIGHT-EMITTING DIODES

5.1 Introduction

From the previous chapter, we attempt to designed and synthesized the OLED materials by changing the acceptor core or the donor moieties for adjusting the property of fluorescent materials in order to achieve high efficiency of OLED devices. However, some fluorophores reveal high emission in the solution state, but their emission was decreased in solid-state caused by aggregated from strong intermolecular π - π interactions, which also known as aggregation-caused quenching (ACQ). To overcome the strong aggregation-caused quenching effect, the first new concept of silole molecules **173**, which can restrict the intramolecular vibration and rotations called aggregation-induced emission (AIE) has been reported by Tang et al. in 2001 (Luo et al., 2001). The proposed conformer of silole, when dissolved in a solvent, is twisted conformer of phenyl peripheries and silole core, which is reduced the fluorescence intensity. On the other hand, when added amounts of water into the solution of the silole, its molecule can be aggregated in the solvent mixture with high water content leads to arise coplanar conformer resulting in the increasing fluorescence intensity. It has been proposed that coplanarisation of chromophores can be induced by aggregation.

The molecular structure and conformational rotamers of 1-methyl-1,2,3,4,5-pentaphenylsilole (**173**) are shown in Figure 5.1.

Figure 5.1 Molecular structure and conformational rotamers of silole molecules **173**.

After that, AIE research is widely interested and AIEgens have been recognized as an important type of advanced functional material for a wide variety of applications such as in OLED devices (X. Zhang et al., 2019), as a Cell Apoptosis Probe (Hu, Gao, Feng, Chen, and Liu, 2015), photosensitizers (Yang et al., 2019).

The naphtho[2,3-c][1,2,5]thiadiazole derivatives consist of naphthothiadiazole core with different aryl substituents that have been reported by Wei et al. in 2008 as shown in Figure 5.2. The results reveal that these NTD derivatives present both carrier transporting property and high fluorescence quantum yield (P. Wei et al., 2008).

Figure 5.2 Molecular structure of NTD derivatives **174-177**.

In 2010, Tang et al. was reported the luminogen comprised of two units of tetraphenylethene (BTPE), which this compound provides 100% fluorescence efficiency. The electroluminescence devices based on BTPE material **178** exhibited the current efficiency up to B7.3 cd/A (Z. Zhao et al., 2010). The molecular structure is shown in Figure 5.3.

Figure 5.3 Molecular structure of BTPE **178**.

Triphenylamine (TPA) was introduced into the TPE molecules in order to tune the hole-transporting property and retain the aggregation-induced emission property. The results revealed that the hybrid molecules, TPATPE **179** and 2TPATPE **180** are practically non-luminescent in the solution state, but in the aggregation state, they can be emitted intensely with fluorescence quantum yields up to 100% (Y. Liu et al., 2011). Their molecular structure is shown in Figure 5.4.

Figure 5.4 Molecular structure of TPATPE **179** and 2TPATPE **180**.

Three compounds $\text{VP}_0\text{-(TPE)}_3$ (**181**), $\text{VP}_3\text{-(TPE)}_3$ (**182**), and $\text{VP}_6\text{-(TPE)}_3$ (**183**) containing triphenylethene and tetraphenylethene moieties linked to phenyl-substituted ethylene with different numbers of phenyl rings (Figure 5.5). These compounds exhibited strong fluorescence emission at a maximum wavelength of 469-493 nm in solid states. Their glass transition temperatures were in the range of 138-180°C and the decomposition temperatures were in the range of 495-557°C. The luminescent devices were fabricated and exhibited turns on a voltage at 6 V and the maximum luminance is observed at 1908 cd/m^2 . The Commission Internationale de l'Eclairage (CIE) chromaticity coordinate values are (0.18, 0.31) at 10 V.

Figure 5.5 Molecular structure of $\text{VP}_0\text{-(TPE)}_3$ (**181**), $\text{VP}_3\text{-(TPE)}_3$ (**182**), and $\text{VP}_6\text{-(TPE)}_3$ (**183**).

The AIEgens containing tetraphenylethene, benzo-2,1,3-thiadiazole and thiophene building blocks, BTPE **178**, BTPETTD **184**, BTPEBTDD **185** have been synthesized and investigated. These molecules emit intense PL in both solution and solid states, which they emitted blue, green, and red emission color in solid states. The OLED device was fabricated and exhibited orange-red color with high luminance and efficiencies of 8330 cd m^{-2} , 6.1 cd A^{-1} and 3.1%, respectively (Z. Zhao et al., 2011). Their molecular structure is shown in Figure 5.6.

Figure 5.6 Molecular structure of BTPE **178**, BTPETTD **184**, BTPEBTDD **185**.

The near-infrared (NIR) fluorophores with the donor-acceptor-donor (D-A-D) system have been designed and synthesized through Stille coupling reactions. The desired molecules containing tetraphenylethene (TPE) moieties and [1,2,5]thiadiazolo [3,4-g]quinoxaline (QTD) or benzo[1,2-c;4,5-c']bis[1,2,5]thiadiazole (BBTD) as acceptors. These compounds exhibited good aggregation-induced emission enhancement (AIEE) property due to the twisted TPE units, which restrict the intramolecular rotation and reduce the π - π stacking. The OLED devices were fabricated and exhibited EL emission spectra peaking from 706 to 864 nm with the external quantum efficiency (EQE) ranged

from 0.89%-0.20% (Du, Qi, Zhang, Ma, and Wang, 2012). Their molecular structure is shown in Figure 5.7.

Figure 5.7 Molecular structures of near IR materials **186-189**.

In 2014, the deep blue AIE emitters have been designed and synthesized. The molecules containing two of TPE groups and the substituents at the 2,2'-positions of BTPE with different sizes, namely methyl-BTPE **190**, isopro-BTPE **191**, Ph-BTPE **192** and Cz-BTPE **193** as shown in Figure 5.8 (Huang et al., 2014).

Figure 5.8 Molecular structures of methyl-BTPE **190**, isopro-BTPE **191**, Ph-BTPE **192** and Cz-BTPE **193**.

The butterfly-shaped NIR chromophore based on the donor-acceptor system, which composed of phenothiazine donor and benzothiadiazole acceptor (PTZ-BZP, **194**) has been investigated. The results revealed that a film of PTZ-BZP **194** displayed strong NIR fluorescence with an emission peak at 700 nm and exhibited quantum efficiency reached to 16% (Yao et al., 2014) The molecular structure of PTZ-BZP **194** is shown in Figure 5.9.

Figure 5.9 Molecular structure of PTZ-BZP **194**.

The AIEgen based on tetraphenylpyrazine (TPP), which could be synthesized using a one-pot procedure under mild reaction conditions as shown in Figure 5.10. The emission color of these compounds can be tuned by varying the substituents on their phenyl rings. The TPP derivatives display good thermal stability and emitted deep-blue to pure blue color due to the various substituents on the phenyl rings (Chen et al., 2015).

Figure 5.10 Synthetic routes to tetraphenylpyrazine (TPP) and its derivative.

The NIR fluorescent material with a D- π -A- π -D system namely 4,4'-(naphtho [2,3-c][1,2,5]thiadiazole-4,9-diyl)bis(N,Ndiphenylaniline) (**NZ2TPA**, **197**) has been synthesized via Suzuki reaction as shown in Figure 5.11. The desired compound shows aggregation-induced emission (AIE) characteristic with a high photoluminescent quantum yield of 60% in the neat film. Moreover, the OLED device based on NZ2TPA was fabricated and exhibited an external quantum efficiency (EQE) of 3.9% with the emission peak at 696 nm (T. Liu et al., 2017).

Figure 5.11 Synthesis of NZ2TPA (**197**).

In 2019, the blue luminogens consisting of anthracene, tetraphenylethene, and carbazole groups, TPE-TAC (**198**) and TPE-TADC (**199**) have been synthesized and

investigated as shown in Figure 5.12. From the studied, they exhibited aggregation-induced emission property with strong blue fluorescence at 455 nm in neat films. The OLEDs devices were fabricated provided blue electroluminescence (EL) at 451 nm ($\text{CIE}_{x,y} = 0.165, 0.141$) and high EL efficiencies of 5.71% (Y. Li et al., 2019).

Figure 5.12 Synthetic procedure of TPE-TAC (198) and TPE-TADC (199).

From the above mentioned, in this chapter, we designed and synthesized the AIE molecules containing the tetraphenylethenes (TPEs) linked to a variety of acceptors in order to achieve the different emission colors from yellow to red with the strong emission in solid-state. The desired molecules with the D-A-D system consist of benzothiadiazole derivative as an electron acceptor bonded to two TPE as the AIE unit. Subsequently, aggregation-induced emission characteristics of the target molecules in the THF/water mixtures have been studied as well as their solvatochromic effects related to their structures.

5.2 Research objectives

5.2.1 To design and synthesize novel AIE materials as an emitter for OLEDs.

5.2.2 To characterize the desired molecules by ^1H -NMR, ^{13}C -NMR, and Mass spectroscopy.

5.2.3 To study the photophysical, electrochemical, and thermal properties by using UV-Visible spectroscopy, fluorescence spectroscopy, cyclic voltammetry, and DSC-TGA techniques.

5.3 Synthetic procedure

5.3.1 Synthetic procedure

Herein, the synthesis of the AIE emitters by the Suzuki cross-coupling reaction of benzothiadiazole, naphthothiadiazole, and *bis*- naphthothiadiazole derivatives with the various boronates in the presence of tetrakis(triphenylphosphine) palladium(0) as a catalyst. After purification, the desired AIE emitters should be obtained (Figure 5.13).

Figure 5.13 The synthetic approach to the synthesis of AIE emitters.

5.3.2 Preparation of the boronates **202** and **203**

The TPE-borolane **202** and TPEH-borolane **203** were achieved from the Miyaura borylation reaction, while TPA-boronic acid **204** was obtained from commercial suppliers and used without further purification. The boronates were obtained from cross-coupling of *bis*(pinacolato)diboron (B_2pin_2) with aryl bromide **200** and **201** using [1,1'-*bis*(diphenylphosphino)ferrocene]dichloropalladium(II) palladium as a catalyst in the presence of potassium acetate in toluene as shown in Figure 5.14.

Preparation of TPEH-borolane **202** and TPE-borolane **203** was achieved by the reaction of 1'-Bis(diphenylphosphino)ferrocene]dichloropalladium(0) followed by the oxidative addition of the aryl boronates. The (acetato)palladium(II) complex was achieved and the reaction of the boronates **202** and **203** in the yield of 80% takes place along with the catalyst regeneration. The borylation of aryl halides described by Miyaura

5.3.3 The synthesis of AIE emitters 17-26

The benzothiadiazole, naphthothiadiazole, and *bis*- naphthothiadiazole derivatives were used as the starting materials in the final step for synthesized AIE emitters via for Suzuki cross-coupling reaction, which could be synthesized on a 100-milligram scale as outlined in Figure 5.16.

Figure 5.16 The synthesis of AIE emitters 17-26.

The first step was the oxidative addition of palladium (0) to the organic halide starting material (**205**) to form the organopalladium species. The second step was metathetic exchange with base gives intermediate, which via transmetalation with the phenylboronic acid forms the organopalladium species. Finally, reductive elimination of the desired product (**17**) restores the original palladium catalyst (0) as shown in Figure 5.17.

Figure 5.17 The mechanism of Suzuki reaction.

The benzothiadiazole, naphthothiadiazole, and *bis*- naphthothiadiazole were reacted with boronates in the presence of sodium carbonate as base via Suzuki reaction to afford the desired product **17-26** in a yield of 14%-97%. After purification, their structures were confirmed by ^1H NMR, ^{13}C NMR, and HRMS spectrometric methods.

The ^1H -NMR spectrum of BT-2TPE (**17**) showed singlet signals of the two protons of benzothiadiazole core at $\delta = 7.72$ ppm. The TPE units showed the doublet signals at $\delta = 7.76$ (4H) and 7.19 (4H) ppm with the coupling constant (J) of 8.7 Hz and other protons were in the range of 7.14-7.05 (30H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 21 aryl carbon signals in the range of $\delta = 154.0$ -126.5 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 796.4323 (required m/z = 796.2912).

The ^1H -NMR spectrum of NT-2TPE (**18**) showed multiplet signals of the four protons of naphthothiadiazole core at $\delta = 7.87$ and 7.33 ppm. The TPE units showed the doublet signals at $\delta = 7.39$ (4H) and 7.26 (4H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.22 - 7.14 (30H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 21 symmetrical aryl carbon signals in the range of $\delta = 151.2$ - 126.1 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 846.5767 (required $m/z = 846.3069$).

The ^1H -NMR spectrum of NT-TPETPA (**19**) showed signals of the four protons of naphthothiadiazole core at $\delta = 8.88$, 8.12 , 7.37 and 7.35 ppm. The TPA units showed the doublet signals at $\delta = 7.53$ (4H) and 7.40 (4H) ppm and other protons were in the range of 7.32 - 7.22 (10H) ppm. The TPE units showed the signals were in the range of 7.22 - 7.11 (15H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 34 symmetrical aryl carbon signals in the range of $\delta = 151.5$ - 122.2 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 759.5536 (required $m/z = 759.2708$).

The ^1H -NMR spectrum of BT-2TPEH (**20**) showed singlet signals of the two protons of benzothiadiazole core at $\delta = 7.71$ ppm. The TPEH units showed singlet signals of the two alkenyl protons at $\delta = 7.05$ ppm. the doublet signals at $\delta = 7.78$ (4H) and 7.19 (4H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.40 - 7.28 (20H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 15 aryl carbon signals in the range of $\delta = 154.0$ - 127.6 ppm. Moreover, High

resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 644.4773 (required m/z = 664.2286).

The ^1H -NMR spectrum of BT-TPETPA (**21**) showed multiplet signals of the two protons of benzothiadiazole core at δ = 7.74 ppm. The TPA units showed the doublet signals at δ = 7.87 (2H) and 7.78 (2H) ppm with the coupling constant (J) of 8.1 Hz. The TPE units showed the multiplet signals at δ = 7.20 (2H) ppm and other protons were in the range of 7.31-7.06 (30H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 32 aryl carbon signals in the range of δ = 154.1-122.9 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 709.5769 (required m/z = 709.2552).

The ^1H -NMR spectrum of FBT-2TPE (**22**) showed singlet signals of the benzothiadiazole proton at δ = 7.70 ppm. The doublet signals of TPE proton at the near F-atom position of δ = 7.76 (2H) and 7.60 (2H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.21-7.05 (34H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 44 aryl carbon signals in the range of δ = 155.1-117.0 ppm.

The ^1H -NMR spectrum of 2FBT-2TPE (**23**) showed doublet signals of TPE units at δ = 7.60 (4H) and 7.21 (4H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.16-7.05 (30H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 23 symmetrical aryl carbon signals in the range of δ = 151.3-118.3 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 832.5317 (required m/z = 832.2724).

The ^1H -NMR spectrum of 2FBT-2TPEH (**24**) showed singlet signals of the two alkenyl protons at $\delta = 7.04$ ppm, doublet signals of TPEH units at $\delta = 7.63$ (4H) and 7.21 (4H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.40-7.28 (20H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 23 symmetrical aryl carbon signals in the range of $\delta = 151.3$ -118.3 ppm.

The ^1H -NMR spectrum of NBT-2TPE (**25**) showed singlet protons of pyridinethiadiazole core at $\delta = 8.76$ ppm. The doublet signals of TPE units at the near N-atom position of $\delta = 8.42$ (2H) and 7.8 (2H) ppm with the coupling constant (J) of 8.1 Hz and other protons were in the range of 7.25-7.06 (34H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 32 symmetrical aryl carbon signals in the range of $\delta = 156.6$ -126.4 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 1565.6174 (required $m/z = 797.2865$).

The ^1H -NMR spectrum of BNT-2TPE (**26**) showed singlet signals of the two protons of *bis*-naphthothiadiazole core at $\delta = 8.99$ ppm. The doublet signals of TPE units at $\delta = 7.94$ (4H) and 7.26 (4H) ppm with the coupling constant (J) of 8.4 Hz and other protons were in the range of 7.26-7.07 (30H) ppm. The ^{13}C -NMR spectrum showed the chemical shift of 23 symmetrical aryl carbon signals in the range of $\delta = 154.0$ -125.1 ppm. Moreover, High resolution mass spectrometry confirmed the identity of the compound with m/z (HRMS) = 904.7764 (required $m/z = 904.2694$).

5.4 Results and discussion

5.4.1 Photophysical properties

The UV-vis absorption and fluorescence spectra of the AIE emitters **17-26** were investigated in dilute toluene solution (10^{-5} - 10^{-6} M) and the neat film by UV-vis and photoluminescence spectroscopies as shown in Figure 5.18 and listed in Table 5.1.

Figure 5.18 UV-vis absorption of AIE emitters in (a) dilute solution in toluene (10^{-5} M) (b) solid film and fluorescence spectra in (c) dilute solution in toluene (10^{-6} M) and (d) solid film.

The results revealed that all AIE compounds **17-26** showed two broad absorption bands, an absorption band around 300 nm corresponding to the π - π^* transition of the donor moieties and an absorption band with a maximum at 400-550 nm assigned to the n- π^* transition leads to occur intramolecular charge-transfer (ICT) between the donor moieties and the acceptor units. All the AIE emitters showed a similar absorption band in solution and in the neat film. NT-2TPE (**18**) and NT-TPETPA (**19**) exhibited strong red-shifted emission band after change the acceptor core from benzothiadiazole to naphthothiadiazole and showed slightly red-shifted emission band when changing to pyridinethiadiazole NBT-2TPE (**25**) and *bis*-naphthothiadiazole BNT-2TPE (**26**) possibly due to the higher degree of conjugation more electron acceptor ability. In addition, the absorption bands of BT-2TPE (**17**) were blue-shifted after the introduction of the fluorine atom onto the benzothiadiazole core possibly due to a collapsing of the planarity of the molecules as can be seen in FBT-2TPE (**22**), 2FBT-2TPE (**23**) molecules. Moreover, their emission displays a slightly red-shifted when changing the TPE donor to TPEH and TPA moieties as can be seen in BT-2TPEH (**20**) and 2FBT-2TPEH (**24**).

The fluorescence spectra of AIE emitters exhibited emission bands with a maximum around 541-706 nm in the toluene solution and the fluorescence spectra in neat films are identical to those in the toluene solution. The emission bands of BT-2TPE (**17**) were blue-shifted after the introduction of the fluorine atom onto the benzothiadiazole core as can be seen in the molecules of FBT-2TPE (**22**), 2FBT-2TPE (**23**), and 2FBT-2TPEH (**24**). When changing the BT to NT, BNT, and NBT core, the emission bands were red-shifted and extended to the NIR region by using NT core with the TPA donor group. The solid-state absorption maximum of BT-2TPE (**17**), NT-

2TPE (**18**), NT-TPETPA (**19**), BT-2TPEH (**20**), BT-TPETPA (**21**), FBT-2TPE (**22**), 2FBT-2TPE (**23**), 2FBT-2TPEH (**24**), NBT-2TPE (**25**), and BNT-2TPE (**26**) was red-shifted by 15, 14, 14, 16, 17, 15, 15, 0, 19, and 148 nm, respectively compared to that of the solution. This bathochromic shift can be attributed to intermolecular interactions in the solid-state. The solid-state emission maximum wavelength of BT-2TPE (**17**), NT-2TPE (**18**), NT-TPETPA (**19**), BT-2TPEH (**20**), BT-TPETPA (**21**), FBT-2TPE (**22**), 2FBT-2TPE (**23**), 2FBT-2TPEH (**24**), NBT-2TPE (**25**), and BNT-2TPE (**26**) was red-shifted by 116, 110, 150, 123, 138, 118, 116, 115, 147, and 67 nm, respectively compared to that of the solution. The optical bandgap energy calculated by the onset of the absorption edge of NT-2TPE (**18**), NT-TPETPA (**19**), BT-2TPEH (**20**), BT-TPETPA (**21**), NBT-2TPE (**25**), and BNT-2TPE (**26**) were decreased compared to BT-2TPE (**17**). On the other hand, the introduction of the fluorine atom onto the benzothiadiazole increased the optical bandgap energy of FBT-2TPE (**22**), 2FBT-2TPE (**23**), 2FBT-2TPEH (**24**) compared to BT-2TPE (**17**) as listed in table 5.1.

5.4.2 Commission International de l'Eclairage (CIE)

Chromaticity diagram and CIExy values of all AIE emitters in dilute toluene solution and in the neat film are shown in Figure 5.19 and summarized in Table 5.2. The results revealed that AIE emitters **17-26** exhibited the high x,y coordinate with yellow-green to orange-red emission color in the solution state, while in solid-state, the emission of FBT-2TPE (**22**), 2FBT-2TPE (**23**), 2FBT-2TPEH (**24**) were blue-shifted,

all AIE emitters exhibited green to orange-red emission color. In solid-state, NT-2TPE (**18**), NT-TPETPA (**19**), and NBT-2TPE (**25**) showed the red color in the NIR region with the CIE_{xy} values of (0.591, 0.408), (0.686, 0.314) and (0.548, 0.449).

5.4.3 Solvatochromic behaviors

Normally, the D-A molecules which containing π - π^* transition presented the solvatochromism in their absorption spectra due to the high polarization of the ground-state molecular structure, while the molecules containing the ICT character, the solvatochromic behavior could be observed in the emission spectra rather than in absorption spectra. In order to study the solvatochromic behavior of all AIE emitters **17-26**, various solvents with different polarities such as hexane, toluene, dichloromethane, tetrahydrofuran, and acetonitrile were selected. The UV-vis and emission spectra of all compounds have been measured. The results revealed that only emission spectra could be observed the bathochromic shifted in polar solvent due to their ICT behavior. The absorption spectra and emission spectra of all AIE emitters **17-26** in different solvents are shown in Figure 5.20.

Figure 5.20 UV-vis absorption and fluorescence spectra of AIE emitters **17-26** in various solvent.

The plots of stokes shift versus solvent polarity parameter (Δf) of all AIE emitters **17-26** were shown in Figure 5.21. The results revealed that the fluorescent properties of all compounds are strongly related to the solvent polarity which might be

from the formation of large charge separation and high dipole moment in the excited state.

Figure 5.21 The plots of stokes shift versus solvent polarity parameter (Δf) AIE emitters **17-26**.

5.4.4 Aggregation induced emission characteristic

The emission spectra of AIE emitters **17-26** with different water fractions in THF/water mixture are shown in Figure 5.22. The maximum emission wavelength of AIE emitters **17-26** was red-shifted, and the maximum emission intensity gradually decreases upon increasing the water fraction up to 60%. However, upon an increase in the water fraction from 60% to 99%, the maximum emission wavelength was blue-shifted, and the maximum emission intensity gradually increases. Due to their intramolecular charge-transfer state between donor and acceptor moieties could be stabilized upon increasing the polarity of the solvents and upon the higher water fraction, their molecules could be the formation of nanoaggregates that can enhance aggregation-induced emission as shown in Figure 5.23.

Figure 5.22 Emission spectra of AIE emitters **17-26** in THF-water mixtures (concentration 10^{-5} M).

Figure 5.23 Relative PL intensity vs water fraction of AIE emitters **17-26**.

5.4.5 Electrochemical properties

The electrochemical characteristics of the AIE emitters **17-26** were measured by cyclic voltammetry. All compounds exhibited reversible oxidation processes upon the anodic sweep as shown in Figure 5.24.

Figure 5.24 CV curves of AIE emitters **17-26** in CH_2Cl_2 solution using 0.1 M Bu_4NPF_6 at a scan rate of 50 mV/s under argon flow.

The first oxidation process assigns to the removal of electrons from the donor moieties, resulting in radical cations. The HOMO levels of all compounds

determined from the onsets of the oxidation potentials were in the range of -5.89 to -5.26 eV, which are nearly values from AC2 method. The LUMO levels determined from the onsets of the reduction potentials were in the range of -3.51 to -3.13 eV. Electrochemical band gaps (E_g^{ele}) determined using the onsets of the oxidation potentials subtracts by the onsets of the reduction potentials were in the range of 1.97-2.72 eV. The electrochemical data are summarized in Table 5.3.

Table 5.3 Electrochemical properties of AIE emitters **17-26**.

5.4.6 Electroluminescence properties

In order to investigate the electroluminescence properties of AIE emitters, OLED devices were fabricated with the following device structure: indium tin oxide ITO(90nm)/PEDOT:PSS(40nm)/NPB(15nm)/TCTA(5nm)/EL(40nm)/TmPyPB(35nm)/LiF(0.5nm):Al(100nm), where these materials were used as the emitting layer (EML) as shown in Figure 5.25. Conductive polymer poly(3,4-ethylenedioxy thiophene):poly(4-styrenesulfonate) (PEDOT: PSS) as hole injection layer, *N,N'*-bis(naphthalen-1-yl)-*N,N'*-bis(phenyl)-benzidine (NPB), 4,4',4''-Tris(carbazol-9-yl)triphenylamine (TCTA), 3,3-di(9H-carbazol-9-yl)biphenyl (mCBP) as a hole-transport layer (HTL), and 1,3,5-Tri(m-pyridin-3-ylphenyl)benzene (TmPyPB) as hole-blocking layer were also used to enable high-performance devices.

Figure 5.25 Schematic energy diagram of OLED devices.

The electroluminescence spectra (EL) of all AIE emitters doped in 3% CBP showed similar features with their fluorescence spectra without the emission of the host materials as shown in Figure 5.26.

Figure 5.26 Normalized electroluminescence spectra at high brightness of OLEDs based on WK series AIE materials 20 wt% in CBP.

The quantum yield of these AIE emitters in powder are summarized in Table 5.4. All AIE emitters show a moderate quantum yield in the range of 2.41-57.55%.

Table 5.4 Quantum yield of AIE emitters **17-26**.

Compounds	Quantum yield (%)
BT-2TPE (17)	43.56
NT-2TPE (18)	13.48
NT-TPETPA (19)	2.41
BT-2TPEH (20)	53.68
BT-TPETPA (21)	57.55
FBT-2TPE (22)	35.87
2FBT-2TPE (23)	45.74
2FBT-2TPEH (24)	44.11
NBT-2TPE (25)	43.38
BNT-2TPE (26)	27.16

The multi-layer devices using AIE emitters as EML were fabricated. The thermal evaporation processed of all AIE emitters emit green, yellow, and red light. No emission shoulder at a longer wavelength due to excimer and exciplex species formed at the interface of the EML and ETL layers, which often occurs in devices fabricated from EMLs with a planar molecular structure, is detected. The devices characteristics based on these materials as an emitter are summarized in Table 5.5. From the results revealed that the external quantum efficiency of OLED devices were in the range of 3.14-4.66%.

Table 5.5 Device characteristics of OLEDs

Emissive layer	%EQE_{max}/V	CE_{max}/V	PE_{max}/V

5.5 Conclusion

In summary, AIE emitters **17-26** were successfully synthesized by a Suzuki-Miyaura cross-coupling reaction using $\text{Pd(PPh}_3)_4$ as the catalyst and K_2CO_3 as a base to give the compounds in a high yield. The desired molecules containing the D-A-D system, which comprised of benzothiadiazole, naphthothiadiazole, and *bis*-naphthothiadiazole as an acceptor core with the AIE activator such as TPE, TPEH as the donor moieties. All AIE emitters exhibited red emission with the strong ICT in solution and showed a strong PL intensity when the molecules were aggregated. From the studies can be concluded that all compounds exhibited aggregation-induced emission characteristics upon increasing the water fraction. The OLEDs device based on AIE emitters exhibited a high external quantum efficiency of 3.14 - 4.66%. We believe that our results could provide a useful guide to design the highly efficient emitter with a high PL intensity in solid-state to be suitable for applications in OLEDs devices.

CHAPTER VI

EXPERIMENTAL

6.1 General remark

The NMR spectra were measured on a Bruker DRX 600 spectrometer, and chemical shifts were reported in ppm using tetramethylsilane as an internal standard. High-resolution mass spectrometry (HRMS) analysis was performed by a Bruker autoflex MALDI-TOF mass spectrometer. The UV-visible absorption spectra were determined on a Perkin Elmer Lambda-1050 UV/Vis/NIR spectrophotometer. The fluorescence spectra, fluorescence quantum yield, and the transient photoluminescence decay profiles of the target molecules were measured using an Edinburgh Instruments FLS980 spectrometer. Cyclic voltammetry was performed using the Autolab PGSTAT101 with a scan rate of 50 mV/s in CH₂Cl₂ solution at room temperature. A platinum plate as the working electrode, a Pt-wire counter electrode, and a saturated calomel electrode (SCE) as the reference electrode was used. The supporting electrolyte was tetrabutylammonium hexafluorophosphate (0.1 M) and ferrocene was selected as the internal standard. Differential scanning calorimetry (DSC) analysis was performed on a METTLER DSC823e thermal analyzer under N₂ atmosphere. Samples were scanned from 25 to 430°C at a heating rate of 10°C/min then rapidly cooled to 25°C and heated at the same heating rate to 430°C. Thermogravimetric analysis (TGA) was carried out on a Seiko EXSTAR 6000 TG/DTA 6300 thermal analyzer at a heating rate of 10°C/min under the N₂ atmosphere.

Tetrahydrofuran (THF) was dried and freshly distilled from sodium/benzophenone under N₂. Solvents were dried and purified by conventional methods prior to use. CH₂Cl₂ for cyclic voltammetry analysis was washed with conc. H₂SO₄ and freshly distilled twice from calcium hydride under N₂. Reagents of commercial quality were used from freshly opened containers or purified by common methods.

Thin-layer chromatography (TLC) was carried out on Merck silica gel F₂₅₄ TLC alumina sheets. Column chromatography used Merck silica gel 60, particle size 0.063-0.200 mm (70-230 mesh) for column chromatography and particle size 0.40-0.063 mm (230-240 mesh) for flash column chromatography. Preparative chromatography (PLC) was carried out on glass supported silica gel using silica-gel 60 F254 for preparative chromatography from Merck.

All moisture-sensitive reactions were carried out under N₂ in the pre-dried glass apparatus.

6.2 General procedure (GP)

6.2.1 GP 1 : Ullmann coupling reaction

A mixture of Ar-NH (9.2 mmol), 3,6-diiodo-9-tosyl-carbazole (4.0 mmol), CuI (2.0 mmol), K₃PO₄ (1.0 mmol), and (±)-*trans*-1,2-diaminocyclohexane (2.0 mmol) in toluene (120 mL) was degassed with N₂ for 5 min and then stirred at reflux under N₂ atmosphere for 48 h. After the mixture was cooled, water (100 mL) was added, and the mixture was extracted with CH₂Cl₂ (50 mL x 3). The combined organic phase was washed with water (100 mL x 2) and brine solution (100 mL), dried over anhydrous Na₂SO₄ and filtered. The solvent was removed to dryness, and the residue was purified by silica gel column chromatography using a mixture of CH₂Cl₂ and hexane as eluent

followed by recrystallization with a mixture of CH_2Cl_2 and methanol to afford the corresponding product.

6.2.2 GP 2 : Alkylation reaction

Pigment red 254 (0.28 mmol), potassium *tert*-butoxide (0.62 mmol) and *N*-Methyl-2-pyrrolidone (NMP) (15 mL) were heated to 60°C. Alkylbromide (0.84 mmol) was added and the mixture was stirred at 60°C for 18 h. After cooling to room temperature then diluted with water (50 mL). The solution was extracted with CH_2Cl_2 (3 x 50 mL), and the combined organic layers, dried over anhydrous Na_2SO_4 and concentrated under reduced pressure. The crude product was purified by column chromatography using a mixture of CH_2Cl_2 and hexane as eluent followed by recrystallization with a mixture of CH_2Cl_2 and methanol to afford the corresponding product.

6.2.3 GP 3 : Suzuki cross-coupling reaction

To a 100 mL flask equipped with an Ar inlet/outlet, a mixture of aryl bromides (1.14 mmol), borolane or boronic acid (1.25 mmol), $\text{Pd}(\text{PPh}_3)_4$ (0.06 mmol), 10 wt % aqueous sodium carbonate solution (10 mL), and toluene (20 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. After the mixture was cooled, CH_2Cl_2 (50 mL) was added. The organic phase was washed with water (50 mL x 2) and brine solution (50 mL), dried over anhydrous Na_2SO_4 and filtered. The solvent was removed to dryness, and the residue was purified by silica gel column chromatography using a mixture of CH_2Cl_2 and hexane as eluent followed by recrystallization with a mixture of CH_2Cl_2 and methanol to afford the corresponding product.

6.2.4 GP 4 : Nucleophilic substitution reaction

A suspension of carbazole derivatives (2.3 mmol) and 60% NaH (3.0 mmol) in DMF (15 mL) was heated at 70°C under nitrogen atmosphere. At this temperature and under vigorous stirring, fluorophenyl sulfone (1.0 mmol) was added. The mixture was stirred at 100°C for 24 h. After cooling to room temperature, the reaction was quenched with water and CH₂Cl₂ (20 ml) was added. The organic phase was washed with water (50 mL × 2) and brine solution (50 ml), dried over anhydrous Na₂SO₄ and filtered. The solvent was removed to dryness, and the residue was purified by silica gel column chromatography using a mixture of CH₂Cl₂ and hexane as eluent followed by recrystallization with a mixture of CH₂Cl₂ and methanol to afford the corresponding sulfone product.

6.2.5 GP 5 : Borylation reaction

Under N₂ atmosphere, aryl bromide (1.0 mmol), bis(pinacolato)diboron (2.0 mmol), KOAc (12 mmol), and Pd(dppf)Cl₂ (0.05 mmol) were dissolved in toluene (20 mL) and heated to 110°C for 24 h. After the reaction solution was cooled to room temperature, the reaction was quenched with water and CH₂Cl₂ (20 ml) was added. The organic phase was washed with water (50 mL × 2) and brine solution (50 ml), dried over anhydrous Na₂SO₄ and filtered. The solvent was removed to dryness, and the residue was purified by silica gel column chromatography using a mixture of CH₂Cl₂ and hexane as eluent followed by recrystallization with a mixture of CH₂Cl₂ and methanol to afford the corresponding borolane product.

6.3 The synthesis

6.3.1 Supplementary data in Chapter 2: the synthesis of DPP dendrimers

3,6-diiodo-9-tosyl-carbazole (**72**)

Carbazole (**71**) (5.0g, 0.030 mmol) was dissolved in 30 ml of acetic acid, potassium iodide (6.5 g, 0.038 mmol) and potassium iodate (6.31 g, 0.030 mmol) were added into the solution. The mixture was refluxed for 4 h. After the reaction solution was cooled to room, the brown solid was separated by rapidly filtered off and washed by hexane and methanol, followed by recrystallization with a mixture of CH_2Cl_2 and methanol to afford the diiodo carbazole in the yield of 62%.

After that, diiodo carbazole (5.03g, 0.012 mmol) and potassium hydroxide (0.74 g, 0.013 mmol) were dissolved in 50 ml of acetone, 4-Toluenesulfonyl chloride (2.52 g, 0.013 mmol) was added into the solution. The mixture was refluxed for 5 h. After the reaction solution was cooled to room temperature the reaction was poured into water and CH_2Cl_2 (20 ml) was added. The organic phase was washed with water (50 mL \times 2) and brine solution (50 ml), dried over anhydrous Na_2SO_4 and filtered. The solvent was removed to dryness, and the residue was purified by silica gel column chromatography using a mixture of CH_2Cl_2 and hexane as eluent followed by recrystallization with a mixture of CH_2Cl_2 and hexane to afford the 3,6-diiodo-9-tosyl-carbazole (**72**) as a solid (4.44 g, 64%).

3,6-di-*tert*-butyl-carbazole (73)

To a solution of carbazole (**71**) (10.0 g, 0.06 mol) in CH₂Cl₂ (80 mL) and CH₃NO₂ (40 mL) were added ZnCl₂ (24.5 g, 0.18 mol). Then 2-chloro-2-methyl propane (19.8 mL, 0.18 mol) was added dropwise. Then the mixture was sonicated for 1 h, the mixture was filtered, washed with hexane followed by recrystallization with a mixture of CH₂Cl₂ and hexane to obtain the 3,6-di-*tert*-butyl-carbazole (**73**) (12.0 g, 72%) as white solid; ¹H-NMR (600 MHz, CDCl₃): δ = 8.09 (s, 2H, -C=CH-C), 7.47 (d, *J* = 10.2 Hz, 2H, -HN-C-CH=CH-C), 7.33 (d, *J* = 10.2 Hz, 2H, -HN-C-CH=CH-C), 1.47 (s, 18H, -C(CH₃)₃) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 142.2, 138.1, 123.5, 123.4, 116.2, 110.0, 34.7, and 32.0 ppm.

G2 (74)

According to GP 1, a mixture of 3,6-di-*tert*-butyl-carbazole (**G1**, **73**) (2.5707 g, 9.2 mmol), 3,6-diiodo-9-tosyl-carbazole (**72**) (2.2928 g, 4.0 mmol), CuI (0.3809 g, 2.0 mmol), K₃PO₄ (2.1227g, 1.0 mmol), and (±)-*trans*-1,2-diaminocyclohexane (0.24 mL, 2.0 mmol) in toluene (120 mL) was refluxed under N₂ atmosphere for 48 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the G2 product as white solid (1.8

g, 62%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 8.38 (s, 1H, NH), 8.14 (s, 2H, $-\text{C}=\text{CH}-\text{C}$), 8.13 (s, 4H, $-\text{C}=\text{CH}-\text{C}$), 7.64 (d, J = 8.4 Hz, 2H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 7.58 (d, J = 8.4 Hz, 2H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 7.42 (d, J = 8.4 Hz, 4H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 7.28 (d, J = 8.4 Hz, 4H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 1.44 (s, 36H, $-\text{C}(\text{CH}_3)_3$) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): δ = 142.5, 140.2, 139.0, 130.5, 126.0, 124.1, 123.5, 123.0, 119.4, 116.2, 111.8, 109.11, 34.73, and 32.0 ppm.

G1hexyl bromide (75)

1,6-Dibromohexane (2.8 mL, 18.0 mmol) was added to a mixture of G1 (73) (1.0 g, 3.6 mmol), KOH (0.81 g, 14.4 mmol), and *N,N*-dimethylformamide (DMF, 50 mL) at 0°C . The mixture was stirred at room temperature for 24 h and then quenched with water and CH_2Cl_2 (20 mL) was added. The organic phase was washed with water (50 mL \times 2) and brine solution (50 mL), dried over anhydrous Na_2SO_4 , and filtered. The solvent was removed to dryness, and the crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) to afford G1hexyl bromide (75) (1.2223 g, 77%) as a white solid; $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 8.10 (s, 2H, $-\text{C}=\text{CH}-\text{C}$), 7.50 (d, J = 8.4 Hz, 2H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 7.30 (d, J = 8.4 Hz, 2H, $-\text{HN}-\text{C}-\text{CH}=\text{CH}-\text{C}$), 4.25 (t, J = 7.2 Hz, 2H, $-\text{N}-\text{CH}_2-\text{CH}_2-\text{C}$), 3.36 (t, J = 6.6 Hz, 2H, $\text{Br}-\text{CH}_2-\text{CH}_2-$), 1.81-1.90 (m, 4H, CH_2-CH_2-), 1.44 (s, 18H, $-\text{C}(\text{CH}_3)_3$), 1.41-1.39 (m, 4H, CH_2-CH_2-) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): δ = 141.5, 139.0, 123.3, 122.7, 116.3, 108.0, 43.0, 34.7, 33.7, 32.6,

32.4, 32.1, 29.0, 28.0, and 26.5 ppm; m/z (MALDI-TOF): 441.333 ($C_{26}H_{36}BrN$ required $m/z = 441.2031$).

G2hexyl bromide (76)

1,6-Dibromohexane (1.1 mL, 6.92 mmol) was added to a mixture of G2 (**74**) (1.0 g, 1.40 mmol), KOH (0.31 g, 5.54 mmol), and *N,N*-dimethylformamide (DMF, 50 mL) at 0°C. The mixture was stirred at room temperature for 24 h and then quenched with water and CH_2Cl_2 (20 mL) was added. The organic phase was washed with water (50 mL \times 2) and brine solution (50 mL), dried over anhydrous Na_2SO_4 , and filtered. The solvent was removed to dryness, and the crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) to afford G2hexyl bromide (**76**) (1.0605 g, 86%) as a white solid; 1H -NMR (600 MHz, $CDCl_3$): δ = 8.18 (s, 2H, $-C=CH-C$), 8.15 (s, 4H, $-C=CH-C$), 7.64 (m, 4H, $-HN-C-CH=CH-C$), 7.44 (m, 4H, $-HN-C-CH=CH-C$), 7.31 (m, 4H, $-HN-C-CH=CH-C$), 4.49 (t, $J = 7.2$ Hz, 2H, $-N-CH_2-CH_2-C$), 3.43 (m, 2H, $Br-CH_2-CH_2-$), 2.09-1.91 (m, 4H, $-CH_2-CH_2-$), 1.46 (s, 36H, $-C(CH_3)_3$), 1.44 (m, 4H, CH_2-CH_2-) ppm; ^{13}C -NMR (150 MHz, $CDCl_3$): δ = 142.5, 140.3, 139.9, 129.9, 125.7, 123.5, 123.4, 123.0, 119.5, 116.2, 109.9, 109.1, 43.5, 34.7, 33.7, 32.6, 31.9, 29.1, 28.0, 27.3, 26.6 ppm; m/z (MALDI-TOF): 883.605 ($C_{58}H_{66}BrN_3$ required $m/z = 883.4440$).

G0DPP (1)

According to GP 2, pigment red 254 (**77**) (0.1000 g, 0.28 mmol), potassium *tert*-butoxide (0.0691 g, 0.62 mmol) and *N*-Methyl-2-pyrrolidone (NMP) (15 mL) were heated to 60°C. 1-bromohexane (0.12 mL, 0.84 mmol) was added and the mixture was stirred at 60°C for 18 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as orange solid (0.0734 g, 50%); ¹H-NMR (600 MHz, CDCl₃): δ = 7.76 (d, 4H, *J* = 8.4 Hz, *ArH*-C(Cl)), 7.50 (d, 4H, *J* = 8.4 Hz, *ArH*), 3.72 (t, 4H, *J* = 7.5 Hz, NCH₂), 1.56 (m, 4H, NCH₂CH₂), 1.21 (m, 12H, CH₂CH₂CH₂), 0.83 (t, 6H, -CH₂CH₃) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 162.5, 147.4, 137.4, 130.0, 129.3, 136.6, 110.0, 41.9, 31.2, 29.7, 29.4, 26.4, 22.5, and 13.9 ppm; *m/z* (MALDI-TOF): 524.4251 (C₃₀H₃₄Cl₂N₂O₂ required *m/z* = 524.1997); IR (ATR): ν_{max} = 2936, 2847, 1686, 1612, 1483, 1374, 1076, 831, 695 cm⁻¹.

G1DPP (2)

According to GP 2, pigment red 254 (**77**) (0.1000 g, 0.28 mmol), potassium *tert*-butoxide (0.0691 g, 0.62 mmol) and NMP (15 mL) were heated to 60°C. G₁hexylbromide (**75**) (0.3720 g, 0.84 mmol) was added and the mixture was stirred at 60°C for 18 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as orange solid (0.0418 g, 14%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.09 (s, 4H, CzH), 7.70 (d, 4H, *J* = 8.4 Hz, ArH-C(Cl)), 7.45-7.49 (m, 8H, ArH and -HN-C-CH=CH-C), 7.23 (d, *J* = 8.4 Hz, 4H, -HN-C-CH=CH-C), 4.18 (t, 4H, *J* = 6.8 Hz, (G₁)NCH₂), 3.69 (t, 4H, *J* = 7.3 Hz, (DPP)NCH₂), 1.78 (m, 4H, m), 1.53 (4H, m, NCH₂CH₂) 1.45 (m, 36H, -C(CH₃)₃), 1.24-1.30 (m, 8H, CH₂CH₂CH₂CH₂) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 162.4, 147.3, 141.5, 138.9, 137.4, 129.9, 129.3, 126.4, 123.2, 122.7, 116.3, 109.9, 107.9, 42.9, 41.8, 34.7, 32.1, 29.3, 29.0, 26.8, 26.6 ppm; m/z (MALDI-TOF): 1078.6823 (C₇₀H₈₀Cl₂N₄O₂ required m/z = 1078.5658); IR (ATR): ν_{max} = 2950, 2868, 2311, 1673, 1605, 1475, 1353, 1082, 797, 716 cm⁻¹.

G2DPP (3)

According to GP 2, pigment red 254 (**77**) (0.0500 g, 0.14 mmol), potassium *tert*-butoxide (0.0350 g, 0.31 mmol) and NMP (10 mL) were heated to 60°C. G₂hexylbromide (**7**) (0.3720 g, 0.42 mmol) was added and the mixture was stirred at 60°C for 18 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as orange solid (0.0418 g, 26%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.17 (s, 4H, CzH), 8.15 (s, 8H, CzH), 7.73 (d, 4H, *J* = 8.4 Hz, ArH-C(Cl)), 7.55-7.61 (m, 8H, -HN-C-CH=CH-C and -HN-C-CH=CH-C), 7.42-7.46 (d, 12H, ArH and -HN-C-CH=CH-C), 7.30 (d, 8H, *J* = 8.4 Hz, -HN-C-CH=CH-C), 4.40 (t, 4H, *J* = 7.2 Hz, (G1)NCH₂), 3.76 (m, 4H, (DPP)NCH₂), 1.94-1.99 (m, 4H, NCH₂CH₂), 1.61-1.65 (m, 4H, NCH₂CH₂CH₂), 1.26-1.46 (m, 80H, CH₂CH₂ and -C(CH₃)₃) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 162.4, 147.3, 142.5, 140.3, 139.9, 137.5, 129.9, 129.4, 126.4, 125.7, 123.5, 123.1, 119.5, 116.2, 110.0, 109.8, 109.1, 43.4, 41.8, 34.7, 32.1, 29.4, 29.0, 26.8, and 26.6 ppm; *m/z* (MALDI-TOF): 1963.0941 (C₁₃₄H₁₄₀Cl₂N₈O₂ required *m/z* = 1963.0476); . IR (ATR): ν_{max} = 2963, 2854, 2359, 1673, 1503, 1258, 811, 606 cm⁻¹.

6.3.2 Supplementary data in Chapter 3: the synthesis of TADF emitters

3,3'-Dibromo-4,4'-difluorodiphenyl sulfone (**131**)

According to a published procedure (N. Li, Shin, Hwang, Lee, and Guiver, 2010), *Bis*(4-fluorophenyl) sulfone (1.0 g, 03.94 mmol) was dissolved in concentrated H₂SO₄ (15mL) at room temperature. To this was added NBS (1.54 g, 2.2 mmol, 2.2 equiv), divided into three portions and added at 15 min intervals. The mixture was

stirred vigorously at room temperature for a further 6h and then poured into crushed ice (~500 g) to precipitate the solids. The precipitated solids were filtered, washed with water (600 mL) and then with 100 mL of n-hexane, and purified by recrystallization from toluene to obtain the product as white solid (0.71 g, 44%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 8.15 (m, 2H, SO_2ArH), 7.88 (m, 2H, (Br)ArH), 7.27 (m, 2H, (F)ArH) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): δ = 163.1, 138.3, 133.6, 129.1, 117.8, and 110.9 ppm.

3,3',5,5'-Tetrabromo-4,4'-difluorodiphenyl sulfone (132)

According to a published procedure (N. Li et al., 2010), *Bis*(4-fluorophenyl) sulfone (1.0 g, 3.94 mmol) was dissolved in concentrated H_2SO_4 (25 mL) at room temperature. To this was added NBS (2.95 g, 16.5 mmol, 4.2 equiv) divided into six portions over a period of 1 h. The mixture was stirred vigorously at room temperature for 2 h, and then the temperature was increased to 60°C and maintained at that temperature for 12 h. The mixture was poured into crushed ice (~500 g) to precipitate the solids. The precipitated solids were filtered, washed with water several times, followed by 100 mL of n-hexane, and finally dried to obtain the product as white solid (1.01 g, 46%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 8.07 (m, 4H, SO_2ArH) ppm.

3,3'-Diphenyl-4,4'-difluorodiphenyl Sulfone (DBDFDPS, 133)

According to GP 3, a mixture of 3,3',5,5'-Tetrabromo-4,4'-difluorodiphenyl sulfone (**132**) (206 mg, 0.5 mmol), phenyl boronic acid (153 mg, 1.25 mmol, 2.5 equiv), Pd(PPh₃)₄ (24 mg, 0.02 mmol), 10 wt % aqueous sodium carbonate solution (7.5 mL), and mixed toluene/THF in the ration of 2:1 (15 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (166 mg, 82%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.06 (m, 2H, SO₂ArH), 7.92 (m, 2H, (Ph)ArH), 7.53-7.42 (m, 10H, PhH and (F)ArH), 7.27 (t, 2H, *J* = 9.3 Hz, PhH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 163.3, 161.6, 137.9, 133.7, 130.7, 129.0, 128.9, 128.7, 117.6, and 117.5 ppm.

3,3',5,5'-Tetraphenyl-4,4'-difluorodiphenyl Sulfone (TBDFDPS, **134**)

According to GP 3, a mixture of 3,3'-dibromo-4,4'-difluorodiphenyl sulfone (**131**) (302 mg, 0.53 mmol), phenyl boronic acid (324 mg, 2.65 mmol, 5.0 equiv), Pd(PPh₃)₄ (25 mg, 0.02 mmol), 10 wt % aqueous sodium carbonate solution (7.5 mL), and mixed toluene/THF in the ration of 2:1 (15 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (172 mg, 58%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.02 (d, 2H, SO₂ArH), 7.56-7.41 (m, 10H, PhH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 163.3, 161.6, 137.9, 133.7, 130.7, 129.0, 128.9, 128.7, 117.6, and 117.5 ppm; ¹³C-NMR

(150 MHz, CDCl_3): $\delta = 137.8, 134.0, 131.6, 131.5, 129.4, 129.3, 129.2, 129.1$, and 128.7 ppm.

3,6-diphenyl-9H-carbazole (**136**)

According to GP 3, a mixture of 3,6-diiodo carbazole (**135**) (1.0 g, 2.4 mmol), phenyl boronic acid (729 mg, 6.0 mmol, 2.5 equiv), $\text{Pd}(\text{PPh}_3)_4$ (111 mg, 0.1 mmol), 10 wt % aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a solid (321 mg, 42%); ^1H -NMR (600 MHz, CDCl_3): $\delta = 8.34$ (s, 2H, CzH), 8.12 (s, 1H, NH), 7.72 (d, 4H, $J = 7.7$ Hz, PhH), 7.69 (d, 2H, $J = 8.3$ Hz, CzH), 7.51 (d, 2H, $J = 8.3$ Hz, CzH), 7.48 (t, 4H, $J = 8.0$ Hz, PhH), 7.34 (t, 2H, $J = 7.3$ Hz, PhH) ppm; m/z (Q-TOF): 319.1292 ($\text{C}_{24}\text{H}_{17}\text{N}$ required $m/z = 319.1361$).

2,7-diphenyl-9H-carbazole (**138**)

According to GP 3, a mixture of 2,7-dibromo carbazole (**137**) (1.0 g, 3.1 mmol), phenyl boronic acid (939 mg, 7.7 mmol, 2.5 equiv), $\text{Pd}(\text{PPh}_3)_4$ (150 mg, 0.04 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N_2 . The reaction mixture was heated at

110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (663 mg, 65%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.18 (s, 1H, *NH*), 8.13 (d, 2H, *J* = 7.8 Hz, *CzH*), 7.71 (d, 2H, *J* = 8.1 Hz, *PhH*), 7.65 (s, 2H, *CzH*), 7.51 (m, 2H, *CzH*), 7.48 (t, 4H, *J* = 7.4 Hz, *PhH*), 7.37 (t, 2H, *J* = 7.1 Hz, *PhH*) ppm; *m/z* (Q-TOF): 319.1299 (C₂₄H₁₇N required *m/z* = 319.1361).

Cz-DPS (4)

According to GP 4, a suspension of carbazole (**139**) (193 mg, 1.15 mmol, 2.3 equiv) and 60 % sodium hydride (60 g, 2.5 mol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, (*Bis*(4-fluorophenyl) sulfone (127 mg, 0.5 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (180 mg, 66%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.29 (d, 4H, *J* = 8.4 Hz, O₂SPh*H*), 8.14 (d, 4H, *J* = 7.9 Hz, *CzH*), 7.84 (d, 4H, *J* = 8.4 Hz, *CzN-PhH*), 7.50 (d, 4H, *J* = 8.4 Hz, *CzH*), 7.44 (t, 4H, *J* = 7.5 Hz, *CzH*), 7.34 (t, 4H, *J* = 7.5 Hz, *CzH*) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 142.8, 140.0, 139.4, 129.4, 127.2, 126.4, 124.0, 121.0, 120.6, and 109.6 ppm; *m/z* (Q-TOF): 548.1002 (C₃₆H₂₄N₂O₂S required *m/z* = 548.1558); . IR (ATR): ν_{max} = 1591, 1510, 1455, 1320, 143, 729, 681, and 600 cm⁻¹.

G1-DPS (5)

According to GP 4, a suspension of 3,6-di-*tert*-butyl-carbazole (G1, **73**) (322 mg, 1.15 mol, 2.3 equiv) and 60 % sodium hydride (60 g, 2.5 mol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, (*Bis*(4-fluorophenyl) sulfone (127 mg, 0.5 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (364 mg, 94%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.24 (d, 4H, *J* = 8.6 Hz, O₂SPhH), 7.82 (d, 4H, *J* = 8.7 Hz, CzN-PhH), 7.49-7.43 (m, 8H, CzH), 1.46 (m, 36H, -C(CH₃)₃) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 144.1, 143.2, 138.8, 138.3, 129.6, 126.6, 124.1, 124.0, 116.5 109.2, 34.8, and 31.9 ppm; *m/z* (MALDI-TOF): 772.4062 (C₅₂H₅₆N₂O₂S required *m/z* = 773.0782); . IR (ATR): ν_{max} = 2963, 2895, 1591, 1496, 1455, 1302, 1150, 824, and 634 cm⁻¹.

3,6-diPhCz-DPS (6)

According to GP 4, a suspension of 3,6-diphenyl-9H-carbazole (**136**) (148 mg, 0.5 mmol, 2.3 equiv) and 60% sodium hydride (40 mg, 1.0 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, (*Bis*(4-fluorophenyl) sulfone (52 mg, 0.2 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (153 mg, 88%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.40 (s, 4H, CzH), 8.32 (d, 4H, *J* = 8.6 Hz, O₂SPhH), 7.89 (d, 4H, *J* = 8.3 Hz, CzN-PhH), 7.72 (d, 8H, *J* = 7.4 Hz, PhH), 7.70 (d, 4H, *J* = 8.7 Hz, CzH), 7.57 (d, 4H, *J* = 8.5 Hz, CzH), 7.50 (t, 4H, *J* = 7.5 Hz, PhH), 7.37 (t, 4H, *J* = 7.5 Hz, PhH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 142.7, 141.5, 139.8, 139.5, 134.8, 129.9, 128.9, 127.3, 127.1, 126.9, 126.1, 124.8, 119.1, and 110.1 ppm; *m/z* (Q-TOF): 853.1968 (C₆₀H₄₀N₂O₂S required *m/z* = 853.2844); IR (ATR): ν_{max} = 1578, 1499, 1475, 1326, 1163 1109, 763 and 606 cm⁻¹.

2,7-diPhCz-DPS (7)

According to GP 4, a suspension of 2,7-diphenyl-9H-carbazole (**138**) (294 mg, 0.92 mmol) and 60 % sodium hydride (80 mg, 2.0 mol, 2.3 equiv) in dry dimethylformamide (DMF) (15 mL) was stirred at 70°C under N₂ atmosphere for 30

minutes. After that, (*Bis*(4-fluorophenyl) sulfone (102 mg, 0.4 mol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (226 mg, 66%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.33 (d, 4H, *J* = 8.6 Hz, O₂SPh*H*), 8.20 (d, 4H, *J* = 8.2 Hz, Cz*H*), 7.91 (d, 4H, *J* = 8.6 Hz, CzN-Ph*H*), 7.66 (s, 4H, Cz*H*), 7.62 (d, 8H, *J* = 7.4 Hz, Ph*H*), 7.58 (d, 4H, *J* = 8.2 Hz, Cz*H*), 7.42 (t, 4H, *J* = 7.7 Hz, Ph*H*), 7.34 (t, 4H, *J* = 7.7 Hz, Ph*H*) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 142.7, 142.6, 141.1, 140.0, 139.5, 130.0, 129.9, 129.9, 128.8, 127.5, 127.4, 127.3, 120.9, 120.8, and 108.2 ppm; *m/z* (Q-TOF): 852.7777 (C₆₀H₄₀N₂O₂S required *m/z* = 853.2844); IR (ATR): ν_{max} = 1598, 1489, 1428, 1299, 1136, 1106, 749, and 709 cm⁻¹.

G1-2Ph-DPS (**8**)

According to GP 4, a suspension of 3,6-di-*tert*-butyl-carbazole (G1, **73**) (161 mg, 0.58 mmol) and 60% sodium hydride (60 mg, 2.5 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, DBDFDPS (**133**) (100 mg, 0.25 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (173 mg, 74%); ¹H-NMR (600 MHz, CDCl₃): δ

=8.36 (d, 2H, $J = 2.0$ Hz, $\text{O}_2\text{SPhH(Ph)}$), 8.15 (dd, 2H, $J = 2.0$ and 8.4 Hz, $\text{O}_2\text{SPhH(Ph)}$), 8.02 (s, 4H, CzH), 7.70 (d, 4H, $J = 8.4$ Hz, G1N-PhH), 7.30-7.28 (m, 4H, G1H), 7.15-7.13 (m, 4H, G1H), 7.08-7.07 (m, 6H, PhH), 6.97 (d, 4H, $J = 8.5$ Hz, PhH), 1.40 (s, 36H, $-\text{C}(\text{CH}_3)_3$) ppm; ^{13}C -NMR (150 MHz, CDCl_3): $\delta = 143.2, 141.6, 140.7, 140.6, 138.8, 137.2, 131.2, 130.7, 128.6, 128.1, 127.9, 127.8, 123.6, 123.6, 116.1, 109.4, 34.7$, and 31.91 ppm; m/z (MALDI-TOF): 924.4772 ($\text{C}_{64}\text{H}_{64}\text{N}_2\text{O}_2\text{S}$ required $m/z = 924.4688$); . IR (ATR): $\nu_{\text{max}} = 2949, 2895, 1483, 1326, 1286, 1157, 797, 702$, and 648 cm^{-1} .

G2-2Ph-DPS (9)

According to GP 4, a suspension of G2, **74** (614 mg, 0.85 mmol) and 60 % sodium hydride (45 mg, 1.85 mmol) in mixed DMF/THF in the ration of 2:1 (20 mL) was stirred at 70°C under N_2 atmosphere for 30 minutes. After that, DBDFDPS (**133**) (150 mg, 0.4 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a white crystal (211 mg, 32%); ^1H -NMR (600 MHz, CDCl_3): $\delta = 8.50$ (s, 2H, $J = 2.0$ Hz, $\text{O}_2\text{SPhH(Ph)}$), 8.39 (d, 2H, $J = 8.4$ Hz, $\text{O}_2\text{SPhH(Ph)}$), 8.13 (s, 12H, G2H), 8.02 (d, 4H, $J = 8.6$ Hz, G2N-

PhH), 7.47-7.42 (m, 12H, G2H), 7.31 (d, 4H, $J = 8.4$ Hz, G2H), 7.25-7.17 (m, 18H, G2H, PhH), 1.45 (s, 72H, $-\text{C}(\text{CH}_3)_3$) ppm; ^{13}C -NMR (150 MHz, CDCl_3): $\delta = 142.7$, 142.0, 141.6, 140.0, 139.7, 139.6, 136.8, 131.5, 131.4, 130.9, 128.9, 128.7, 128.4, 127.8, 125.9, 124.2, 123.5, 123.2, 119.2, 116.2, 111.3, 109.0, 34.7, 32.0, and 29.7 ppm; m/z (MALDI-TOF): 1809.1216 ($\text{C}_{128}\text{H}_{124}\text{N}_6\text{O}_2\text{S}$ required $m/z = 1808.9506$); IR (ATR): $\nu_{\text{max}} = 2969, 2882, 1489, 1266, 1154, 804, 695, \text{ and } 606 \text{ cm}^{-1}$.

G1-4Ph-DPS (10)

According to GP 4, a suspension of 3,6-di-*tert*-butyl-carbazole (G1, **73**) (47 mg, 0.17 mmol) and 60 % sodium hydride (10.0 mg, 0.04 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N_2 atmosphere for 30 minutes. After that, TBDFDPS (**134**) (40 mg, 0.07 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO_2 , $\text{CH}_2\text{Cl}_2/\text{hexane}$) and recrystallization by CH_2Cl_2 and methanol to afford the product as a white crystal (50 mg, 94%); ^1H -NMR (600 MHz, CDCl_3): $\delta = 8.36$ (s, 4H, O_2SPhH), 7.85 (s, 4H, G1H), 7.16 (d, 4H, $J = 8.8$ Hz, G1H), 7.20-6.90 (m, 20H, PhH), 6.76 (d, 4H, $J = 8.8$ Hz, G1H), 1.34 (m, 36H, $-\text{C}(\text{CH}_3)_3$) ppm; ^{13}C -NMR (150 MHz, CDCl_3): $\delta = 143.3, 142.5, 140.1, 137.8, 136.9, 136.4, 128.7, 127.1, 126.8, 126.7, 122.2, 122.1, 114.7, 108.5, 33.5, 30.9, \text{ and } 30.8$ ppm; m/z (MALDI-TOF): 1076.5097

($C_{76}H_{72}N_2O_2S$ required $m/z = 1076.5315$); IR (ATR): $\nu_{\max} = 2963, 2882, 1483, 1340, 1266, 1150, \text{ and } 695 \text{ cm}^{-1}$.

G2-4Ph-DPS (11)

According to GP 4, a suspension of G2, **74** (299 mg, 0.41 mmol) and 60 % sodium hydride (22 mg, 0.9 mmol) in mixed DMF/THF in the ration of 2:1 (15 mL) was stirred at 70°C under N_2 atmosphere for 30 minutes. After that, TBDFDPS (**134**) (100 mg, 0.18 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a white crystal (32 mg, 9%); 1H -NMR (600 MHz, $CDCl_3$): $\delta = 8.44$ (s, 4H, O_2SPhH), 8.11 (s, 8H, G2H), 7.96 (s, 4H, G2H), 7.42 (d, 8H, $J = 8.6$ Hz, G2H), 7.34 (d, 4H, $J = 9.1$ Hz, G2H), 7.22-7.21 (m, 4H, G2H), 7.18-7.13 (m, 28H, G2H, PhH), 1.44 (s, 72H, - $C(CH_3)_3$) ppm; ^{13}C -NMR (150 MHz, $CDCl_3$): $\delta = 144.3, 142.6, 140.0, 139.8, 137.1, 130.8, 130.0, 128.6, 128.5, 127.9, 125.6, 123.8, 123.5, 123.1, 119.0, 116.2, 111.5, 109.0, 34.7, \text{ and } 32.0$ ppm; m/z (MALDI-TOF): 1961.3507 ($C_{140}H_{132}N_6O_2S$ required

$m/z = 1961.0132$); IR (ATR): $\nu_{\max} = 2960, 2901, 1483, 1272, 1157, 797, 716$, and 614 cm^{-1} .

3,6-diPhCz-4Ph-DPS (12)

According to GP 4, a suspension of 3,6-diphenyl-9H-carbazole (**136**) (110 mg, 0.35 mmol) and 60% sodium hydride (30 mg, 0.75 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N_2 atmosphere for 30 minutes. After that, TBDFDPS (**134**) (84 mg, 0.15 mol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a white crystal (131 mg, 38%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): $\delta = 8.36$ (s, 4H, O_2SPhH), 8.17 (s, 4H, CzH), 7.63 (d, 8H, $J = 8.0 \text{ Hz}$, CzPhH), 7.46-7.42 (m, 12H, CzH and CzPhH), 7.30 (t, 4H, $J = 7.5 \text{ Hz}$, CzPhH), 7.07-6.98 (m, 24H, CzH and $\text{O}_2\text{SPh-PhH}$) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): $\delta = 144.4, 141.6, 141.5, 140.3, 137.2, 137.1, 133.3, 129.9, 128.8, 128.7, 128.4, 128.3, 127.7, 127.2, 127.1, 126.6, 125.3, 123.8, 118.5$, and 110.4 ppm ; m/z (MALDI-TOF): 1157.2931 ($\text{C}_{84}\text{H}_{56}\text{N}_2\text{O}_2\text{S}$ required $m/z = 1157.4096$); IR (ATR): $\nu_{\max} = 1598, 1475, 1258, 1143, 1089, 1014, 756$, and 695 cm^{-1} .

2,7-diPhCz-4Ph-DPS (13)

According to GP 4, a suspension of 2,7-diphenyl-9H-carbazole (**138**) (221 mg, 0.69 mmol) and 60% sodium hydride (60 mg, 1.5 mol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, TBDFDPS (**134**) (161 mg, 0.30 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (47 mg, 14%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.37 (s, 4H, O₂SPhH), 7.92 (d, 4H, *J* = 8.1 Hz, CzH), 7.46 (d, 8H, *J* = 7.3 Hz, CzPhH), 7.38 (t, 8H, *J* = 7.3 Hz, CzPhH), 7.33 (d, 4H, *J* = 8.2 Hz, CzH), 7.29 (t, 64H, *J* = 7.2 Hz, CzPhH), 7.08-7.07 (m, 8H, O₂SPh-PhH), 7.05 (s, 4H, CzH), 7.04-7.00 (m, 12H, O₂SPh-PhH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 144.1, 141.7, 141.6, 140.9, 139.1, 137.4, 137.1, 130.0, 128.7, 128.4, 128.3, 127.8, 127.4, 127.3, 127.1, 122.2, 120.2, 119.8, and 108.8 ppm; *m/z* (MALDI-TOF): 1157.2896 (C₈₄H₅₆N₂O₂S required *m/z* = 1157.4096); IR (ATR): ν_{max} = 1591, 1462, 1421, 1333, 1143, 756, and 681 cm⁻¹.

6.3.3 Supplementary data in Chapter 4: the synthesis of TADF dendrimers

***Bis*(4-(2,7-dibromocarbazole)phenyl) sulfone (160)**

According to GP 4, a suspension of 2,7-dibromocarbazole (**159**) (1.47 g, 4.5 mmol) and 60 % sodium hydride (394 mg, 9.85 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N₂ atmosphere for 30 minutes. After that, *Bis*(4-fluorophenyl) sulfone (0.5 g, 2.0 mmol) was added into a solution. The mixture was stirred at 100°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a white crystal (0.59 g, 35%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.34 (d, 4H, *J* = 8.7 Hz, O₂SPh*H*), 7.95 (d, 4H, *J* = 8.7 Hz, Cz*H*), 7.78 (d, 4H, *J* = 8.6 Hz, Ph*HN*), 7.57 (s, 4H, Cz*H*), and 7.45 (d, 4H, *J* = 8.4 Hz, Cz*H*) ppm; *m/z* (Q-TOF): 859.7586 (C₃₆H₂₀Br₄N₂O₂S required *m/z* = 859.7979)

2-bromo fluorene (162)

Fluorene (10.0 g, 60 mmol) was dissolved in acetone (100 mL) and NBS (11.8 g, 66 mmol) was added. The solution was refluxed for 3 h. The mixture was extracted with dichloromethane (50 mL x 3). The combined organic phase was washed with brine and dried over sodium sulfate. Then filtered and the solvent was removed to dryness. The crude product was recrystallization by hexane to afford the product as a

white crystal (3.5 g, 24%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 7.75 (d, 1H, J = 7.5 Hz, PhH), 7.68 (s, 1H, BrPhH), 7.64 (d, 1H, J = 7.4 Hz, BrPhH), 7.53 (d, 1H, J = 7.0 Hz, PhH), 7.50 (d, 1H, J = 7.0 Hz, BrPhH), 7.38 (t, 1H, J = 7.0 Hz, PhH), 7.32 (t, 1H, J = 7.0 Hz, PhH), and 3.89 (s, 2H, CH_2) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): δ = 145.4, 143.0, 140.9, 140.8, 130.0, 128.4, 127.3, 127.1, 125.2, 121.3, 120.6, 120.1, and 36.9 ppm; m/z (Q-TOF): 243.9702 ($\text{C}_{13}\text{H}_9\text{Br}$ required m/z = 243.9888).

Dibromohexyl-2-bromo fluorene (**164**)

1,6-Dibromohexane (19.50 mL, 0.12 mol) was added to a mixture of 2-bromo fluorene **163** (3.50 g, 0.014 mol) and tetrabutylammonium bromide (TBAB) (0.09 g, 0.3 mmol). Subsequently, 50 wt % sodium hydroxide aqueous solution (30 mL) was added to the mixture. The mixture was stirred at room temperature for 24 h and then quenched with water and CH_2Cl_2 (20 mL) was added. The organic phase was washed with water (50 mL \times 2) and brine solution (50 mL), dried over anhydrous Na_2SO_4 , and filtered. The solvent was removed to dryness under vacuum, and the crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) to afford Dibromo hexyl-2-bromo fluorene (**164**) as a colorless liquid (1.9331 g, 66%); $^1\text{H-NMR}$ (600 MHz, CDCl_3): δ = 7.66 (m, 1H, BrPhH), 7.55 (m, 1H, BrPhH), 7.46-7.45 (m, 2H, BrPhH and PhH), 7.33-7.31 (m, 3H, PhH), 3.28 (t, 2H, CH_2), 1.99-1.90 (m, 4H, fluorene CH_2CH_2), 1.68-1.63 (m, 4H, G1CH_2), 1.21-1.16 (m, 4H, fluorene CH_2CH_2), 1.21-1.16 (m, 4H, $\text{G1CH}_2\text{CH}_2$), 1.09-1.05 (m, 4H, CH_2CH_2), and 0.64-0.57 (m, 4H, CH_2CH_2) ppm; $^{13}\text{C-NMR}$ (150 MHz,

CDCl_3): $\delta = 152.7, 150.1, 140.3, 140.2, 130.2, 127.7, 127.2, 126.2, 122.9, 121.2, 121.1, 119.9, 55.4, 40.2, 33.9, 32.7, 29.1, 27.8, \text{ and } 23.6$ ppm; m/z (Q-TOF): 568.8058 ($\text{C}_{25}\text{H}_{31}\text{Br}_3$ required $m/z = 567.9976$).

G1hexyl-2-bromo fluorene (**165**)

A suspension of 3,6-di-*tert*-butyl-carbazole (G1, **73**) (1.97 g, 7.04 mmol, 2.3 equiv) and potassium hydride (858 mg, 15.3 mmol) in dry dimethylformamide (DMF) (10 mL) was stirred at 70°C under N_2 atmosphere for 30 minutes. After that, G1hexyl fluorene bromide **165** (1.74 g, 3.06 mmol) was added into a solution. The mixture was stirred at room temperature for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a white crystal (2.64 g, 89%); ^1H -NMR (600 MHz, CDCl_3): $\delta = 8.07$ (s, 4H, CzH), 7.63 (m, 1H, BrPhH), 7.52 (m, 1H, BrPhH), 7.45 (d, 4H, $J = 8.7$ Hz, CzH), 7.43-7.38 (m, 2H, BrPhH and PhH), 7.29 (m, 1H, PhH), 7.20-7.18 (m, 2H, CzH and PhH), 4.09 (t, 4H, CH_2), 1.82-1.89 (m, 4H, fluorene CH_2CH_2), 1.65-1.60 (m, 4H, G1 CH_2), 1.44 (s, 36H, $\text{C}(\text{CH}_3)_3$), 1.15-1.06 (m, 8H, CH_2CH_2), and 0.59-0.50 (m, 4H, CH_2CH_2) ppm; m/z (MALDI-TOF): 966.5436 ($\text{C}_{65}\text{H}_{79}\text{BrN}_2$ required $m/z = 966.5427$).

TPA-2-bromo fluorene (167)

A mixture of 2-bromofluorenone **166**, triphenylamine in methanesulfonic acid was heated at 160°C with constant stirring under N₂ atmosphere for 24 h. The cooled mixture was extracted with CH₂Cl₂ (20 ml). The organic phase was washed with Na₂CO₃, dried over anhydrous Na₂SO₄, and filtered. The solvent was removed to dryness under vacuum, and the crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) to afford the corresponding product **167** as a white solid (3.63 g, 65%); ¹H-NMR (600 MHz, CDCl₃): δ = 7.71 (d, 1H, *J* = 7.2 Hz, BrPh*H*), 7.61 (d, 1H, *J* = 8.4 Hz, BrPh*H*), 7.55 (s, 1H, BrPh*H*), 7.47 (d, 1H, *J* = 7.8 Hz, Ph*H*), 7.40 (d, 1H, *J* = 7.8 Hz, Ph*H*), 7.35 (t, 1H, *J* = 7.0 Hz, Ph*H*), 7.30 (t, 1H, *J* = 7.0 Hz, Ph*H*), 7.22 (t, 8H, *J* = 7.8 Hz, TPA*H*), 7.05 (d, 8H, *J* = 7.8 Hz, TPA*H*), 7.03 (d, 4H, *J* = 8.4 Hz, TPA*H*), 6.99 (t, 4H, *J* = 8.4 Hz, TPA*H*), and 6.90 (d, 4H, *J* = 8.4 Hz, TPA*H*) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 153.8, 151.6, 147.6, 146.6, 139.2, 139.0, 138.8, 130.7, 129.5, 129.3, 129.9, 128.1, 127.7, 126.4, 124.7, 123.0, 121.6, 121.4, 120.3, and 64.7 ppm; *m/z* (Q-TOF): 730.7290 (C₄₉H₃₅BrN₂ required *m/z* = 730.1984).

G1hexyl fluorene boronate (170)

According to GP 5, G1hexyl fluorene bromide (**165**) (1.0 g, 1.03 mmol), bis (pinacolato)diboron (0.53 g, 2.07 mmol), KOAc (1.22 g, 12.42 mmol), and Pd(dppf)Cl₂ (38 mg, 0.05 mmol) were dissolved in dry toluene (30 mL) and heated to 110°C under N₂ atmosphere for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (0.85 g, 81%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.05 (s, 4H, CzH), 7.80 (m, 1H, BrPhH), 7.72 (s, 1H, BrPhH), 7.68 (t, 2H, PhH), 7.45 (d, 4H, J = 8.7 Hz, CzH), 7.30-7.22 (m, 3H, PhH), 7.17 (d, 4H, J = 8.7 Hz, CzH), 4.07 (t, 4H, CH₂), 1.97-1.86 (m, 4H, fluoreneCH₂CH₂), 1.63-1.60 (m, 4H, G1CH₂), 1.44 (s, 36H, C(CH₃)₃), 1.36 (s, 12H, BO₂C(CH₃)₃), 1.13-1.04 (m, 8H, CH₂CH₂), and 0.57-0.52 (m, 4H, CH₂CH₂) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 144.3, 138.9, 133.8, 128.7, 127.6, 126.7, 123.2, 122.8, 122.6, 120.2, 119.0, 116.2, 107.9, 83.7, 54.9, 42.9, 40.2, 34.6, 32.1, 31.9, 31.8, 29.6, 28.8, 26.8, 24.9, and 23.4 ppm; m/z (MALDI-TOF): 1014.5417 (C₇₁H₉₁BN₂O₂ required m/z = 1014.7174).

TPA fluorene boronate (172)

According to GP 5, TPA-2-bromo fluorene (**169**) (1.0 g, 1.40 mmol), bis (pinacolato)diboron (0.70 g, 2.74 mmol), KOAc (1.60 g, 16.4 mmol), and Pd(dppf)Cl₂ (50 mg, 0.06 mmol) were dissolved in toluene (30 mL) and heated to 110°C under N₂ atmosphere for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (0.92 g, 86%); ¹H-NMR (600 MHz, CDCl₃): δ = 7.84-7.83 (m, 2H, BrPhH), 7.78-7.48 (m, 2H, BrPhH and PhH), 7.42 (d, 1H, *J* = 7.8 Hz, PhH), 7.35 (t, 1H, *J* = 7.0 Hz, PhH), 7.29 (t, 1H, *J* = 7.0 Hz, PhH), 7.20 (t, 8H, *J* = 7.8 Hz, TPAH), 7.08-7.05 (m, 12H, TPAH), 6.97 (t, 4H, *J* = 8.4 Hz, TPAH), 6.90 (d, 4H, *J* = 8.4 Hz, TPAH) and 1.36 (s, 12H, BO₂C(CH₃)₃) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 152.3, 150.9, 147.7, 146.1, 143.1, 139.8, 139.6, 134.4, 132.2, 129.1, 129.0, 128.1, 127.3, 126.3, 124.3, 123.2, 122.7, 120.5, 119.4, 83.8, 64.6, and 24.9 ppm; *m/z* (Q-TOF): 778.7762 (C₅₅H₄₇BN₂O₂ required *m/z* = 778.3731).

TADF dendrimers (14)

According to GP 3, a mixture of *Bis*(4-(2,7-dibromocarbazole)phenyl)sulfone (**160**) (175 mg, 0.2 mmol), G1hexyl fluorene borolane (**170**) (1.0 g, 1.0 mmol, 5.0 equiv), Pd(PPh₃)₄ (12 mg, 0.01 mmol), 10 wt % aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (0.213 g, 25%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.17 (d, 4H, *J* = 8.1 Hz, O₂SPh*H*), 8.03 (m, 20H, G1*H* and Cz*H*), 7.70-7.66 (m, 12H,

fluorene H and CzNPh H), 7.62 (d, 4H, J = 8.2 Hz, CzNPh H), 7.59-7.57 (m, 12H, fluorene H and CzNPh H), 7.37 (dd, 4H, G1 H), 7.19 (m, 12H, fluorene H), 7.10 (d, 16H, J = 8.2 Hz, G1 H), 4.00 (t, 16H, , fluorene CH_2), 1.94 (m, 16H, G1 CH_2), 1.38 (s, 144H, C(CH_3) $_3$), 1.07-1.03 (m, 32H, CH_2CH_2), and 0.57-0.52 (m, 4H, CH_2CH_2) ppm; ^{13}C -NMR (150 MHz, $CDCl_3$): δ = 151.3, 150.5, 141.3, 141.0, 140.6, 140.5, 140.4, 140.3, 139.5, 138.9, 129.9, 127.2, 126.9, 126.4, 123.1, 122.9, 122.7, 122.6, 121.7, 121.1, 120.8, 120.1, 119.9, 116.2, 108.1, 107.9, 55.0, 42.8, 40.4, 34.6, 32.0, 29.6, 28.8, 26.7, and 23.6 ppm; m/z (MALDI-TOF): 1014.5417 ($C_{296}H_{336}N_{10}O_2S$ required m/z = 4094.6219). IR (ATR): ν_{max} = 2956, 2854, 1475, 1448, 1318, 1265, 792, and 732 cm^{-1} .

TADF dendrimers (**15**)

According to GP 3, a mixture of *Bis*(4-(2,7-dibromocarbazole)phenyl) sulfone (**160**) (150 mg, 0.12 mmol), octyl fluorene boronate (**171**) (465 mg 0.60 mmol, 5.0 equiv), $Pd(PPh_3)_4$ (10.5 mg, 0.006 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (30 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. The crude product was purified

by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a solid (0.120 g, 49%); ^1H -NMR (600 MHz, CDCl_3): δ = 8.37 (d, 4H, J = 8.2 Hz, O_2SPhH), 8.22 (d, 4H, J = 8.2 Hz, CzNPhH), 7.99 (d, 4H, J = 8.5 Hz, CzH), 7.78 (s, 4H, CzH), 7.72 (d, 4H, J = 7.6 Hz, CzH), 7.66-7.64 (m, 8H, PhH), 7.61-7.59 (m, 8H, PhH), 7.33-7.27 (m, 12H, PhH), 2.00-1.97 (m, 16H, fluorene CH_2), 1.18-1.13 (m, 16H, fluorene CH_2CH_2), 1.10-1.03 (m, 64H, fluorene $\text{CH}_2\text{CH}_2\text{CH}_2$), 0.77 (t, 24H, CH_2CH_3), and 0.67-0.65 (m, 16H, CH_2CH_3) ppm; ^{13}C -NMR (150 MHz, CDCl_3): δ = 151.6, 150.9, 142.8, 141.1, 140.6, 140.5, 140.5, 140.3, 139.5, 130.0, 127.2, 127.1, 126.7, 126.2, 123.0, 122.8, 121.9, 121.1, 120.7, 119.9, 119.7, 108.1, 55.2, 40.3, 31.7, 29.9, 29.2, 23.8, 22.6, and 14.0 ppm; m/z (Q-TOF): 2101.8084 ($\text{C}_{152}\text{H}_{184}\text{N}_2\text{O}_2\text{S}$ required m/z = 2101.4079); IR (ATR): ν_{max} = 2945, 2849, 1598, 1449, 1332, 1159, 1105, 825, and 748 cm^{-1} .

TADF dendrimers (16)

According to GP 3, a mixture of *Bis*(4-(2,7-dibromocarbazole)phenyl)sulfone (**160**) (200 mg, 0.23 mmol), TPA fluorene boronate (**172**) (910 mg, 1.17 mmol, 5.0 equiv), Pd(PPh₃)₄ (14 mg, 0.05 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (0.35 g, 48%); ¹H-NMR (600 MHz, CDCl₃): δ = 8.19 (d, 4H, *J* = 8.6 Hz, O₂SPhH), 8.14 (d, 4H, *J* = 8.0 Hz, fluoreneH), 7.85 (d, 4H, *J* = 8.4 Hz, CzNPhH), 7.74 (d, 4H, *J* = 8.1 Hz, fluoreneH), 7.70 (d, 8H, *J* = 12.0 Hz, fluoreneH), 7.62-7.58 (m, 12H, fluoreneH and CzN), 7.53 (d, 4H, *J* = 8.4 Hz, fluoreneH), 7.42-7.40 (m, 4H, fluoreneH), 7.22-7.21 (m, 8H, fluoreneH), 7.16 (t, 32H, *J* = 8.1 Hz, TPAH), 7.10 (t, 16H, *J* = 8.4 Hz, TPAH), 7.02 (d, 32H, *J* = 7.4 Hz, TPAH), and 6.94-6.88 (m, 32H, TPAH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 152.4, 151.8, 147.6, 146.3, 142.6, 140.9, 140.8, 140.1, 139.6, 139.5, 129.9, 129.1, 128.9, 127.7, 127.5, 127.0, 126.8, 126.2, 125.3, 124.4, 123.2, 123.0, 122.7, 121.0, 120.8, 120.5, 120.2, 108.1, and 64.6 ppm; *m/z* (Q-TOF): 3149.8115 (C₂₃₂H₁₆₀N₁₀O₂S required *m/z* = 3149.2446); IR (ATR): ν_{max} = 1585, 1489, 1325, 1268, 1148, 759, and 689 cm⁻¹.

6.3.4 Supplementary data in Chapter 5: the synthesis of AIE emitters

TPEH dioxaborolane (**202**)

According to GP 5, 2-(4-Bromophenyl)-1,1-diphenylethene (**200**) (1.0 g, 2.98 mmol), bis (pinacolato)diboron (1.52 g, 5.96 mmol), KOAc (3.50 g, 35.8 mmol), and Pd(dppf)Cl₂ (122 mg, 0.15 mmol) were dissolved in dry toluene (30 mL) and heated to 110°C under N₂ atmosphere for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (1.20 g, 53%); ¹H-NMR (600 MHz, CDCl₃): δ = 7.57 (d, 2H, *J* = 7.9 Hz, PhHBO₂), 7.34-7.28 (m, 8H, PhH), 7.20-7.18 (m, 2H, PhH), 7.01 (d, 2H, *J* = 7.9 Hz, =CHPhH), and 6.98 (s, 1H, =CH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 143.5, 143.3, 140.2, 140.2, 134.4, 130.4, 128.8, 128.6, 128.2, 128.1, 127.7, 127.6, 127.5, 83.7, 24.7 ppm; m/z (Q-TOF): 382.2226 (C₃₂H₃₁BO₂ required m/z = 382.2104).

TPE dioxaborolane (**203**)

According to GP 5, 1-(4-Bromophenyl)-1,2,2-triphenylethylene (**201**) (500 mg, 1.22 mmol), bis (pinacolato)diboron (620 mg, 2.44 mmol), KOAc (1.44 g, 14.6 mmol), and Pd(dppf)Cl₂ (50 mg, 0.06 mmol) were dissolved in toluene (20 mL) and heated to 110°C under N₂ atmosphere for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as white solid (448 mg, 81%); ¹H-NMR (600 MHz, CDCl₃): δ = 7.53 (d, 2H, *J* = 7.6 Hz, PhHBO₂) and 7.09-6.99 (m, 15H, =CHPhH and PhH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 146.8, 143.7, 143.6, 143.6, 141.4, 140.9,

134.1, 131.4, 131.3, 131.3, 130.7, 127.7, 127.6, 126.5, 126.4, 126.4, 83.7, and 24.9 ppm;

m/z (MALDI-TOF): 458.3458 ($C_{32}H_{31}BO_2$ required $m/z = 458.2417$).

BT-2TPE (17)

According to GP 3, a mixture of 4,7-dibromobenzo[*c*][1,2,5]thiadiazole (**205**) (100 mg, 0.34 mmol), TPE dioxaborolane (**203**) (467 mg, 1.02 mmol, 3.0 equiv), $Pd(PPh_3)_4$ (20 mg, 0.02 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a solid (250 mg, 92%): mp 260°C; 1H -NMR (600 MHz, $CDCl_3$): $\delta = 7.76$ (d, 4H, $J = 8.3$ Hz, BTP*hH*), 7.72 (s, 2H, B*T*H), 7.18 (d, 4H, $J = 8.2$ Hz, TPE*PhH*), and 7.14-7.05 (m, 30H, TPE*PhH*) ppm; ^{13}C -NMR (150 MHz, $CDCl_3$): $\delta = 154.0, 143.8, 143.7, 143.6, 143.6, 141.5, 140.5, 135.3, 132.6, 131.6, 131.5, 131.4, 131.3, 128.4, 127.9, 127.8, 127.7, 127.6, 126.6, 126.5, \text{ and } 126.4$ ppm; m/z (Q-TOF): 796.4323 ($C_{58}H_{40}N_2S$ required $m/z = 796.2912$).

NT-2TPE (18)

According to GP 3, a mixture of 4,9-dibromonaphtho[2,3-*c*][1,2,5]thiadiazole (**206**) (100 mg, 0.29 mmol), TPE dioxaborolane (**203**) (332 mg, 0.725 mmol, 2.5 equiv), Pd(PPh₃)₄ (17 mg, 0.015 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (105 mg, 43%): mp 230°C; ¹H-NMR (600 MHz, CDCl₃): δ = 7.87 (dd, 2H, *J* = 3.4 and 6.9 Hz, NTPh*H*), 7.38 (d, 4H, *J* = 8.1 Hz, TPEPh*H*), 7.34 (dd, 2H, *J* = 3.1 and 7.1 Hz, NTPh*H*), 7.26 (d, 4H, *J* = 8.1 Hz, TPEPh*H*), 7.22-7.10 (m, 30H, TPEPh*H*) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 151.2, 143.8, 143.6, 143.5, 143.4, 141.7, 140.8, 134.6, 132.0, 131.5, 131.4, 131.3, 130.6, 130.0, 128.2, 127.8, 127.7, 127.0, 126.6, 126.5, and 126.1 ppm; *m/z* (Q-TOF): 846.5767 (C₆₂H₄₂N₂S required *m/z* = 846.3069).

NT-TPETPA (19)

According to GP 3, a mixture of 4,9-dibromonaphtho[2,3-*c*][1,2,5]thiadiazole (**206**) (100 mg, 0.29 mmol), TPE dioxaborolane (**203**) (332 mg, 0.725 mmol, 2.5 equiv), Pd(PPh₃)₄ (17 mg, 0.015 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol

to afford the corresponding intermediate as a solid. After that, the Suzuki reaction of a mixture of the intermediate (100 mg, 0.17 mmol), triphenyl boronic acid (**204**) (75 mg, 0.255 mmol), Pd(PPh₃)₄ (10 mg, 0.0085 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were refluxed under N₂. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as red solid (96 mg, 75%): mp 300°C; ¹H-NMR (600 MHz, CDCl₃): δ = 8.12 (dd, 2H, NTPh*H*), 7.88 (dd, 2H, NTPh*H*), 7.38 (d, 4H, *J* = 8.1 Hz, TPEPh*H*), 7.34 (dd, 2H, *J* = 3.1 and 7.1 Hz, NTPh*H*), 7.53 (d, 2H, *J* = 8.4 Hz, TPAPh*H*), 7.39 (d, 2H, *J* = 8.3 Hz, NTPh*H*), 7.37-7.31 (m, 6H, NTH and TPAH), 7.28-7.26 (m, 8H, TPAH), and 7.22-7.07 (m, 19H, TPEH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 151.5, 151.3, 147.8, 147.6, 143.8, 143.6, 143.5, 143.4, 141.7, 140.8, 134.7, 132.2, 132.1, 131.9, 131.5, 131.5, 131.4, 131.3, 130.7, 130.0, 129.8, 129.7, 129.4, 127.8, 127.7, 127.2, 127.0, 126.6, 126.5, 126.2, 126.1, 125.2, 123.4, and 122.2 ppm; m/z (Q-TOF): 759.5536 (C₅₄H₃₇N₃S required m/z = 759.2708).

BT-2TPEH (**20**)

According to GP 3, a mixture of 4,7-dibromobenzo[*c*][1,2,5]thiadiazole (**205**) (150 mg, 0.51 mmol), TPEH dioxaborolane (**202**) (585 mg, 1.53 mmol, 3.0 equiv), Pd(PPh₃)₄ (30 mg, 0.025 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ration of 2:1 (20 mL) were added under N₂.

The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (319 mg, 97%): mp 250°C; ¹H-NMR (600 MHz, CDCl₃): δ = 7.77 (d, 4H, *J* = 8.4 Hz, TPEHPhH), 7.71 (s, 2H, BTH), 7.39-7.28 (m, 20H, TPEH) 7.18 (d, 4H, *J* = 8.3 Hz, TPEHPhH), and 7.05 (s, 2H, TPEH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 154.0, 143.3, 143.2, 140.4, 137.5, 135.6, 132.7, 130.4, 129.8, 128.8, 128.8, 128.2, 127.8, 127.6, and 127.5 ppm; *m/z* (Q-TOF): 644.4773 (C₄₆H₃₂N₂S required *m/z* = 664.2286).

BT-TPETPA (21)

According to GP 3, a mixture of 4,7-dibromobenzo[*c*][1,2,5]thiadiazole (**205**) (100 mg, 0.34 mmol), TPEH dioxaborolane (**202**) (467 mg, 1.02), Pd(PPh₃)₄ (20 mg, 0.017 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the corresponding intermediate. After that, the Suzuki reaction of a mixture of the intermediate (50 mg, 0.09 mmol), triphenyl boronic acid (**204**) (75 mg, 0.255 mmol), Pd(PPh₃)₄ (10 mg, 0.0085 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were refluxed under N₂. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and

recrystallization by CH_2Cl_2 and methanol to afford the product as red solid (48 g, 74%): mp 175°C ; $^1\text{H-NMR}$ (600 MHz, CDCl_3): $\delta = 7.87$ (d, 2H, $J = 8.4$ Hz, TPAPhH), 7.78 (d, 2H, $J = 8.1$ Hz, TPAPhH), 7.73 (m, 2H, BTH), 7.30-7.18 (m, 12H, TPAH and TPEPhH), and 7.13-7.05 (m, 15H, TPEH) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): $\delta = 154.1$, 154.0, 148.1, 147.5, 143.8, 143.7, 143.6, 143.6, 141.5, 140.6, 135.3, 132.6, 132.1, 131.6, 131.5, 131.4, 131.4, 130.9, 129.9, 129.3, 128.3, 128.0, 127.8, 127.7, 127.6, 127.3, 126.6, 126.5, 126.5, 124.9, 123.3, and 122.9 ppm; m/z (Q-TOF): 709.5769 ($\text{C}_{50}\text{H}_{35}\text{N}_3\text{S}$ required $m/z = 709.2552$).

FBT-2TPE (22)

According to GP 3, a mixture of 4,7-dibromo-5-fluorobenzo[c][1,2,5]thiadiazole (**207**) (100 mg, 0.32 mmol), TPE dioxaborolane (**203**) (440 mg, 0.96 mmol, 3.0 equiv), $\text{Pd}(\text{PPh}_3)_4$ (20 mg, 0.016 mmol), 10 wt % aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a solid (252 mg, 97%): mp 195°C ; $^1\text{H-NMR}$ (600 MHz, CDCl_3): $\delta = 7.77$ (d, 2H, $J = 8.0$ Hz, BTPhH), 7.60-7.58 (m, 3H, BTH and TPEPhH), 7.20-7.18 (m, 4H, TPEPhH), and 7.14-7.05 (m, 30H, TPEPhH) ppm; $^{13}\text{C-NMR}$ (150 MHz, CDCl_3): $\delta = 158.8$, 155.1, 151.0, 144.6, 143.8, 143.7, 143.6, 143.6, 143.5, 143.5, 141.8, 141.6, 140.5, 140.3, 133.9, 133.4, 133.3, 131.7, 131.5, 131.4, 131.4, 131.3, 131.3,

131.2, 129.8, 129.8, 129.2, 128.4, 127.8, 127.8, 127.7, 127.7, 127.6, 127.6, 126.6, 126.6, 126.5, 125.5, 126.5, 126.4, 119.5, 119.3, 117.1, and 117.0 ppm; m/z (MALDI-TOF): 814.2445 ($C_{58}H_{38}F_2N_2S$ required m/z = 814.2818).

2FBT-2TPE (23)

According to GP 3, a mixture of 4,7-dibromo-5,6-difluorobenzo[*c*][1,2,5]thiadiazole (**208**) (100 mg, 0.3 mmol), TPE dioxaborolane (**203**) (413 mg, 0.9 mmol, 3.0 equiv), $Pd(PPh_3)_4$ (20 mg, 0.015 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N_2 . The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO_2 , CH_2Cl_2 /hexane) and recrystallization by CH_2Cl_2 and methanol to afford the product as a solid (230 mg, 92%): mp 280°C; 1H -NMR (600 MHz, $CDCl_3$): δ = 7.60 (d, 4H, J = 8.1 Hz, 2FBTPhH), 7.20 (d, 4H, J = 8.1 Hz, TPEPhH), and 7.16-7.05 (m, 30H, TPEPhH) ppm; ^{13}C -NMR (150 MHz, $CDCl_3$): δ = 151.3, 150.4, 149.6, 149.4, 144.5, 143.6, 143.5, 143.5, 141.9, 140.3, 131.5, 131.4, 131.3, 129.8, 128.3, 127.8, 127.7, 127.6, 126.7, 126.5, 126.5, 118.4, and 118.3 ppm; m/z (Q-TOF): 832.5317 ($C_{58}H_{38}F_2N_2S$ required m/z = 832.2724).

2FBT-2TPEH (24)

According to GP 3, a mixture of 4,7-dibromo-5,6-difluorobenzo[*c*][1,2,5]thiadiazole (**208**) (100 mg, 0.30 mmol), TPEH dioxaborolane (**202**) (344 mg, 0.90 mmol, 3.0 equiv), Pd(PPh₃)₄ (20 mg, 0.015 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (166 mg, 81%): mp 270°C; ¹H-NMR (600 MHz, CDCl₃): δ = 7.62 (d, 4H, *J* = 8.3 Hz, 2FBTPhH), 7.39-7.27 (m, 20H, TPEH), 7.20 (d, 4H, *J* = 8.3 Hz, TPEHPhH), and 7.04 (s, 2H, TPEH) ppm; ¹³C-NMR (150 MHz, CDCl₃): δ = 151.2, 151.2, 150.4, 149.5, 149.4, 143.8, 143.3, 140.2, 138.3, 130.3, 130.2, 129.6, 128.8, 128.5, 128.3, 127.8, 127.6, 127.4, 118.3, 113.3, 118.3, and 118.2 ppm; *m/z* (Q-TOF): 680.1294 (C₅₈H₃₈F₂N₂S required *m/z* = 680.2098).

NBT-2TPE (25)

According to GP 3, a mixture of 4,7-dibromo-[1,2,5]thiadiazolo[3,4-*c*]pyridine (**209**) (100 mg, 0.34 mmol), TPE dioxaborolane (**203**) (467 mg, 1.02 mmol,

3.0 equiv), Pd(PPh₃)₄ (20 mg, 0.017 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (167 mg, 62%): mp 240°C; ¹H-NMR (600 MHz, CDCl₃): δ = 8.76 (a, 1H, NBTH), 8.42 (d, 2H, *J* = 8.1 Hz, NBTPH), 7.80 (d, 2H, *J* = 8.1 Hz, NBTPH), 7.25-7.21 (m, 4H, NBTPHTPE), and 7.14-7.05 (m, 30H, TPEPhH); ¹³C-NMR (150 MHz, CDCl₃): δ = 156.6, 151.7, 149.8, 146.2, 144.4, 143.6, 143.6, 143.5, 143.5, 142.5, 142.0, 141.8, 140.4, 140.4, 134.8, 132.5, 131.9, 131.7, 131.4, 131.4, 131.3, 131.3, 129.2, 128.2, 127.9, 127.8, 127.7, 126.7, 126.7, 126.6, 126.5, and 126.4 ppm; *m/z* (Q-TOF): 797.5906 (C₅₇H₃₉N₃S required *m/z* = 797.2865).

BNT-2TPE (26)

According to GP 3, a mixture of 5,10-dibromonaphtho[1,2-*c*:5,6-*c'*]bis([1,2,5]thiadiazole) (**210**) (120 mg, 0.30 mmol), TPE dioxaborolane (**203**) (344 mg, 0.75 mmol, 3.0 equiv), Pd(PPh₃)₄ (15 mg, 0.0125 mmol), 10 wt% aqueous sodium carbonate solution (10 mL), and mixed toluene/THF in the ratio of 2:1 (20 mL) were added under N₂. The reaction mixture was heated at 110°C for 24 h. The crude product was purified by column chromatography (SiO₂, CH₂Cl₂/hexane) and recrystallization by CH₂Cl₂ and methanol to afford the product as a solid (37 mg, 14%): mp > 350°C;

^1H -NMR (600 MHz, CDCl_3): δ = 8.99 (s, 2H, BNTH), 7.94 (d, 4H, J = 8.3 Hz, NBTPPhH), 7.24 (m, 4H, NBTPPhH), and 7.14-7.05 (m, 30H, TPEPhH); ^{13}C -NMR (150 MHz, CDCl_3): δ = 153.9, 153.8, 144.4, 143.7, 143.6, 141.7, 140.4, 134.8, 133.3, 131.7, 131.4, 131.4, 131.3, 128.6, 127.9, 127.8, 127.7, 126.7, 126.6, 126.5, 125.2, and 125.1 ppm; m/z (Q-TOF): 904.0083 ($\text{C}_{57}\text{H}_{39}\text{N}_3\text{S}$ required m/z = 904.2694).

CHAPTER VII

CONCLUSION

In summary, we demonstrated the design strategy and synthesis of novel organic emitters based on D-A-D type with the unique character in each molecule as discussed in detail below;

In the first series, we design and synthesize the red emitters containing diketopyrrolopyrrole linked to the end-capped dendronized carbazole via the alkyl chain. From the study, we success to synthesize the target molecules by using the N-alkylation reaction with the moderate yield. We obtain emitters with high solubility, high emissive ability and reduce the π - π stacking interaction of DPP fluorophore as well as improve amorphous glass-forming ability and thermal stability of the material (T_{5d} = 333, 411, and 416°C, for G0DPP (1), G1DPP (2), and G2DPP (3)), respectively. The devices based on G1DPP as an emitter achieve the EQE of 2.90%, and the CIE coordinates of (0.415, 0.483).

In the second series, we designed the target molecules with the TADF characteristic, that molecular structure composed of D- π -A- π -D system which behaves like a “push-pull” architecture to obtain a small ΔE_{ST} and separated the HOMO and LUMO. Novel TADF emitters consist of *bis*(4-carbazolephenyl) sulfone as an acceptor core and carbazole derivatives as a donor moiety, and benzene as the π -linker. All emitters exhibited deep blue emission with strong ICT and showed a slight red shift when changing the donor moieties to a more strongly electron-donating group.

To further demonstrate the character of TADF, the emission decays in dilute toluene solution under argon and oxygen atmosphere and time-resolved emission spectrum (TRES) of these TADF compounds were investigated. The results revealed that the photoluminescence quantum yield of all compounds decreased when exposed to oxygen and the lifetimes were estimated to be 4-19 ns for prompt fluorescence and 36-600 ns for delayed fluorescence under argon atmosphere.

Moreover, from TRES measurement, the prompt component and the delayed component are identical, which can be concluded that the delayed component is originated from the fluorescence. Therefore, we can conclude that this strategy for designed TADF molecules is an effective method to achieve efficient TADF.

After that, the third series, the TADF dendrimers was designed and synthesized. The generation of carbazole dendrons leads three-dimensional molecular conformations and the spatial distribution of the HOMO and LUMO of the molecule. All TADF dendrimers can be dissolved in an organic solvent and exhibited blue emission with strong fluorescence intensity. However, only TPAfluorene-DPS (**16**) reveal the ICT characteristic, which might be from the more spatial distribution of the HOMO and LUMO of G1hexylfluorene (**14**) and octylfluorene (**15**). In addition, their dendritic structure, which arises from G1 and TPA moieties leads to increased T_g resulting in the thermal property of these materials.

In the last series, we designed the emitters by using the AIEgens to solve the strong aggregation-caused quenching effect. The Suzuki-Miyaura cross-coupling reaction of benzothiadiazole, naphthothiadiazole, and *bis*- naphthothiadiazole with the AIE activator such as TPE, TPEH as the donor moieties to afford the AIE emitters. The results revealed that the AIE molecules containing the TPE linked to a variety of

acceptors exhibited the different emission colors from yellow to red with the strong ICT in solution and showed a strong PL intensity when the molecules were aggregated in a high ratio of water fraction. The OLEDs device based on AIE emitters exhibited a high external quantum efficiency of 3.14-4.66%. We believe that our results could provide a useful guide to design the highly efficient emitter with a high PL intensity in solid-state to be suitable for applications in OLEDs devices.

CURRICULUM VITAE

Name	Wipaporn Kitisriworaphan
Date of Birth	8 May 1980
Place of Birth	Tha Uthen district, Nakhon Phanom
Education	2002 Bachelor's degree in Chemistry at Mahasarakham University 2008 Master's degree in Organic Chemistry at Khon Kaen University
Grants and Fellowships	The National Research Council of Thailand (NRCT) in 2018
Position and Place of Work	Lecturer at Udon Thani Rajabhat University

มหาวิทยาลัยเทคโนโลยีสุรนารี
