จงสุทามณี สิทธิเวช : การกักอัด Li-N-H ในการเก็บไฮโดรเจน เพื่อการปรับปรุงคุณสมบัติทางจลนศาสตร์ และยับยั้งการปลดปล่อย NH₃ (COMPACTION OF Li-N-H BASED HYDROGEN STORAGE FOR KINETIC IMPROVEMENT AND SUPPRESSION OF NH₃ RELEASE) อาจารย์ที่ปรึกษา : รองศาสตราจารย์ ดร.ระพี อุทเคอ, 56 หน้า

คำสำคัญ: การดูดซับไฮโดรเจน/ ไฮโดรด์ของโลหะ/ จลนพลศาสตร์ / ท่อนาโนคาร์บอน/ การจัดเก็บไฮโดรเจน/ โลหะทรานซิชัน/ การผันกลับได้/ การปลดปล่อยไฮโดรเจน

ลิเทียมเอไมด์ (LiNH₂) เป็นหนึ่งในวัสดุที่มีแนวโน้มในการกักเก็บไฮโดรเจนได้ดี เนื่องจากมีปริมาณไฮโดรเจนตามทฤษฎีสูง (8.7 wt. %) อย่างไรก็ตาม ก๊าซแอมโมเนีย (NH₃) ที่ปล่อยออกมาระหว่างการสลายตัวของ LiNH₂ จะเป็นพิษต่อตัวเร่งปฏิกิริยาของเซลล์เชื้อเพลิง (PEMFCs) แม้ว่าจะใช้สารประกอบไฮไดรด์ (RHC) ระหว่าง LiNH₂ และ LiH ที่สามารถแก้ปัญหานี้ได้ แต่มีการสังเกตว่ามีการปล่อย NH₃ บางส่วนและจลนพลศาสตร์ที่ไม่ดีด้วยเมื่อจำนวนรอบที่เพิ่มขึ้น จึงมีการเสนอวิธีการบำบัดผสมสารด้วยลูกบอลที่ใช้พลังงานการหมุนสูงรวมทั้งเติมตัวเร่งปฏิกิริยาและสารเติมแต่งจำพวกคาร์บอนเพื่อปรับปรุงคุณสมบัติทางจลนพลศาสตร์ของสารประกอบ LiNH₂-LiH ในงานปัจจุบัน มีการแสดงผลของตัวเร่งปฏิกิริยาที่เป็นโลหะทรานซิชันแฮไลด์ (TiF₄) และท่อนาโนคาร์บอนที่มีผนังหลายชั้น (MWCNTs) ต่อประสิทธิภาพการปลดปล่อยและกักเก็บไฮโดรเจนของ LiNH₂-LiH ที่ถูกกักอัดและบรรจุในถังเก็บไฮโดรเจนขนาดเล็ก ซึ่งแสดงผลการเร่งปฏิกิริยาของ TiF₄ ต่อการแตกตัว/การรวมตัวกันใหม่ของไฮโดรเจนรวมถึงการนำความร้อนที่ดีขึ้นและการซึมผ่านของไฮโดรเจนจากท่อ MWCNTs และเป็นประโยชน์ต่อการดูดซับไฮโดรเจนที่แสดงในผลการทดลองโดยปฏิกิริยาแบบขั้นตอนเดียวและอุณหภูมิที่ต่ำกว่าในช่วง 150-350 °C (100 °C จาก LiNH₂-LiH ที่ไม่มีตัวเร่งปฏิกิริยาและสารเติมแต่งที่ถูกกักอัดเช่นเดียวกัน) ร่วมกับช่วงอุณหภูมิที่ราบและอัตราการไหลของไฮโดรเจนคงที่ (50 sccm) สูงสุด 30 นาทีระหว่างกระบวนการปลดปล่อยไฮโดรเจนด้วยแท่งกักเก็บสารขนาดเล็ก ความจุของไฮโดรเจนในระหว่างรอบการกักเก็บและปลดปล่อยไฮโดรเจน เพิ่มขึ้นจาก 1.90-2.40 เป็น 3.10-4.70 โดยน้ำหนัก % H₂ (ตั้งแต่ 29 ถึง 80% ของความจุทางทฤษฎี) ที่น่าสนใจคือ Li₅TiN₃ ที่ตรวจพบได้จากการหมุนเวียนรอบการกักเก็บและปลดปล่อยไฮโดรเจน จะดูดซับ NH₃ เพื่อสร้างสารประกอบ Li₅TiN₃(NH₃)_x มีส่วนสนับสนุนคุณสมบัติการดูดซับไฮโดรเจนของระบบ LiNH₂-LiH อย่างไรก็ตาม การขยายตัว/การหดตัวของตัวอย่างเม็ดเมื่อรอบการกักเก็บและปลดปล่อยไฮโดรเจนเพิ่มขึ้น ส่งผลให้เกิดการเสีรูปร่างและ/หรือรอยแตก อาจทำให้เกิดการปลดปล่อย NH₃ ระหว่างจำนวนรอบที่มากขึ้น เช่นนี้จึงมีการเสนอแนวคิดในการประกบเม็ด LiNH₂-LiH ด้วยชั้นของสาร LiH ปริมาณ 10-30 wt. %

พบว่าเม็ด $\text{LiNH}_2\text{-LiH}$ ที่ประกบด้วย LiH ไม่แสดงสัญญาณของการปล่อย NH_3 ด้วยความจุ H_2 3.5–4.0 wt. % ในรอบที่ 1 เมื่อวนเป็นรอบ (รอบที่ 2-6) การสลายตัวของเม็ด $\text{LiNH}_2\text{-LiH}$ ที่ประกบด้วย 10 wt. % LiH แสดงสัญญาณ NH_3 ในขณะที่มี 30 wt. % LiH ปล่อยเฉพาะ H_2 ที่มีความจุ 2.3–2.6 โดยน้ำหนัก % H_2 ไม่เพียงแต่การปลดปล่อยไฮโดรเจนที่มีประสิทธิภาพและกระบวนการย้อนกลับของตัวอย่างที่มีน้ำหนัก 30 wt. % $\text{LiH-sandwiched LiNH}_2\text{-LiH}$ ถูกอธิบายโดยผลการทดลองที่เพียงพอและความเสถียรเชิงกลของชั้น LiH ในเม็ดสารตัวอย่างเท่านั้น แต่ยังรวมถึงการก่อตัวของเฟสที่แอคทีฟใหม่ ($\text{LiH}_{1-x}\text{F}_x$ และ $\text{Li}_2\text{NH}_{1-y}\text{F}_y$) อีกด้วย

CHONGSUTTHAMANI SITTHIWET : COMPACTION OF Li-N-H BASED HYDROGEN STORAGE FOR KINETIC IMPROVEMENT AND SUPPRESSION OF NH₃ RELEASE.

THESIS ADVISOR : ASSOC. PROF. RAPEE UTKE. Ph.D. 56 pp.

Keyword : HYDROGEN SORPTION/ METAL HYDRIDES/ KINETICS / CARBON NANOTUBES/ HYDROGEN STORAGE/ TRANSITION METALS/ REVERSIBILITY/ DEHYDROGENATION

Lithium amide (LiNH₂) is one of the most promising hydrogen storage materials due to its high theoretical hydrogen content (8.7 wt. %) and low cost. However, NH₃ gas released during LiNH₂ decomposition is poisonous for PEMFCs' catalysts. Although the reactive hydride composites (RHCs) between LiNH₂ and LiH can solve this problem, partial emission of NH₃ and poor kinetics with the enhanced cycling numbers are observed. High-energy ball milling as well as catalytic and additive doping have been proposed to improve the properties of LiNH₂-LiH composite. In the present work, the effects of transition metal-based catalyst (TiF₄) and multi-walled carbon nanotubes (MWCNTs) on de/rehydrogenation performance of compacted LiNH₂-LiH in small hydrogen storage tank are discussed. Catalytic effects of TiF₄ on hydrogen dissociation/recombination and the improved thermal conductivity and hydrogen permeability from MWCNTs benefit hydrogen sorption. The single-step reaction and lower temperature in range of 150-350 °C (100 °C lower than the compacted LiNH₂-LiH without additives) together with long plateau temperature and constant hydrogen flow rate (50 sccm) up to 30 min during dehydrogenation in the small tank are presented. The hydrogen capacities during de/rehydrogenation cycles increase from 1.90-2.40 to 3.10-4.70 wt. % H₂ (from 29 to up to 80% of theoretical capacity). Interestingly, Li₅TiN₃ detected upon cycling absorbs NH₃ to form Li₅TiN₃(NH₃)_x, favoring hydrogen sorption properties of LiNH₂-LiH system. However, the expansion/contraction of the pellet samples upon de/rehydrogenation cycles results in deformation and/or cracks. This possibly causes NH₃ release during cycling. The idea of sandwiching LiNH₂-LiH pellet with LiH layers (10-30 wt. %) is proposed. The LiH-sandwiched LiNH₂-LiH pellets show no sign of NH₃ release with the hydrogen capacities of 3.5-4.0 wt. % H₂ in the 1st cycle. Upon cycling (the 2nd-6th cycles), the decomposition of LiH-sandwiched LiNH₂-LiH

pellets with 10 wt. % LiH shows NH_3 signal, while that with 30 wt. % LiH releases only hydrogen with the storage capacities of 2.3–2.6 wt. % H_2 . Effective dehydrogenation and reversibility of the 30 wt. % LiH-sandwiched LiNH_2 -LiH pellet are explained by not only sufficient content and mechanical stability of LiH layers but also the formation of the new active phases ($\text{LiH}_{1-x}\text{F}_x$ and $\text{Li}_2\text{NH}_{1-y}\text{F}_y$).

ACKNOWLEDGEMENTS

This work would have never been accomplished without the contribution of many people. Firstly, I would like to thank my supervisor, Assoc. Prof. Dr. Rapee Utke for her expert guidance, support, discussions, encouragement, putting up with my moaning in many years, and always believing in me over the course of my thesis.

I also would like to thank my co-supervisor, Dr. Prieew Eiamlamai from National Energy Technology Center, National Science, and Technology Development Agency for her great help and support and gratefully acknowledged for valuable help with the experimental work and kind suggestions during my visits to National Metal and Materials Technology Center.

I wish to gratefully acknowledge the financial support I have received from the Thailand Graduate Institute of Science and Technology (TGIST), Thailand (TG-33-19-60-015D) which enables me to continue my study after my bachelor's degree.

Also, I would like to thank all members of the Hydrogen Storage Material Lab and Solid-state Chemistry at SUT for their help, fulfillment, discussions, and friendship.

I would like to thank The Synchrotron Light Research Institute (Public Organization), Nakhon Ratchasima, Thailand, and the people from Mechanical workshop at Facility Building 1 (F1) SUT.

Finally, I would also like to thank my parents for their encouragement and moral support in every step of my academic career.

CHAPTER I

INTRODUCTION

1.1 Hydrogen energy

Alternative energies are of significant interest regarding the increase in global temperature, air pollution, and demand for fossil fuels with the depletion of crude oil resources. From Figure 1.1, the release of CO₂ per capita during 2001-2019 increases from 1.65 to 1.75 tCO₂/MWh in the afrika, whereas that in Europe decreases continuously to ~ 1.00 tCO₂/MWh (Dematteis et al., 2021). These trends are the implementation of greater uses of renewable energies in Europe that are beneficial in the reduction of CO₂ emissions.

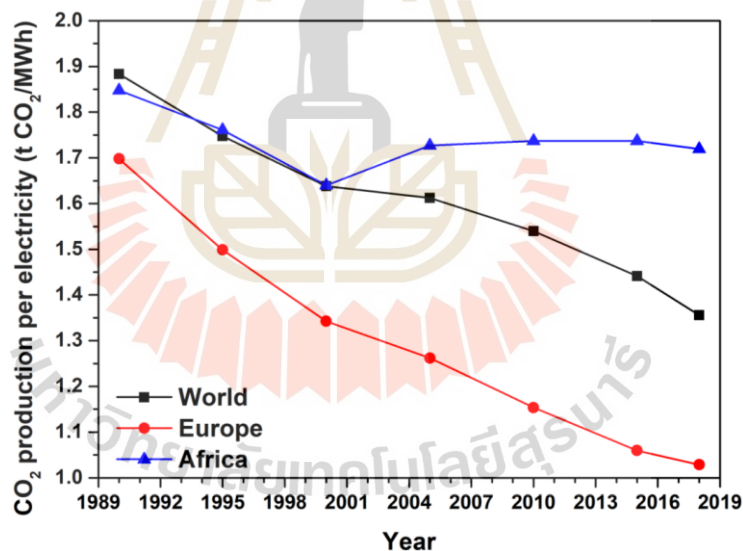

Figure 1.1 Global carbon dioxide (CO₂) production per electricity (Dematteis et al., 2021).

For Thailand, the government has drafted a plan to reduce greenhouse gas emissions, mostly from transportations and industries by aiming to increase the use of renewable.

energy up to 8-20% of the country's energy consumption within 2036(Thailand Power Development Plan, 2015). One of the most efficient renewable energies is hydrogen energy because of its high energy density (142 MJ kg^{-1}), great variety of sources (e.g., water, biomass, and organic matters), and low environmental impact (e.g., use in fuel cells) (Jain et al., 2010). Hydrogen is classified based on how the production process impacts the environment (Figure 1.2).

Figure 1.2 Visualization of the hydrogen production routes with a specific color. (<http://www.chem4us.be/blue-green-gray-the-colors-of-hydrogen/>).

Firstly, brown or gray hydrogen is produced by gasification or steam methane reforming (SMR) of hydrocarbon or fossil fuels. The products are a mixture of H_2 and CO_2 . Therefore, this method does not reduce carbon even though hydrogen gas is clean energy. Next, blue hydrogen uses hydrocarbon or fossil fuels as raw materials, while the obtained CO_2 is captured and used to produce other forms of renewable fuels. (Carbon Capture & Storage Technology). The last one is green hydrogen, which produced no CO_2 emissions using clean electricity from renewable energy sources, such as solar or wind power, to electrolyze water splitting. Among all hydrogen types,

green hydrogen is the most environmentally friendly (Hydrogen, 2021). Hydrogen energy is classified into two categories according to applications, i.e., (1) portable energy storage systems often used in applications requiring fast charging, such as mobile phones and electric vehicles and (2) stationary energy storage systems. Hydrogen energy in all sections consists of productions, storages, and utilizations in the fuel cell system (Jena et al., 2011). From Figure 1.3, hydrogen is produced from water splitting using renewable sources (e.g., sun and wind) through an electrolyzer, stored in the storage tank, and supplied to fuel cells to produce electricity. (Sharaf and Orhan et al., 2014). Our work has been focused on hydrogen storage materials and systems.

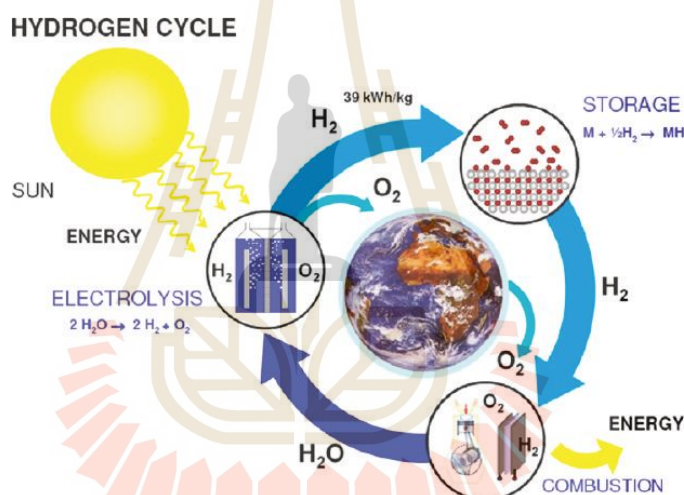

Figure 1.3 Hydrogen cycle (Jena, 2011).

2.2 Hydrogen storages methods and applications

Hydrogen can be stored by physical- and material-based methods (Figure 1.4) (Ren et al., 2017). For the physical-based method, the current technology practically used in the market is compressed hydrogen gas under 70 MPa with gravimetric and volumetric capacities of 5.7 wt. % H_2 and 40 gH_2/L , respectively. Although hydrogen capacities of the compressed gas is satisfied according to US-DOE targets (Table 2), its heavy and bulky tank as well as safety concerns due to high pressure still obstruct the practical uses. For cryogenic liquid, hydrogen is stored at low temperature ($\leq 20\text{K}$) to obtain higher volumetric hydrogen capacity ($70 \text{ kgH}_2\text{m}^{-3}$). However, large thermal losses

and the cost of insulation for storage tanks and hydrogen stations hinder its applications. Thus, physically and chemically material-based storage methods have been proposed. Hydrogen can be stored physically in microporous materials with high surface area through Van der Waals interaction and chemically in metal and complex hydrides (Ren et al., 2017).

Figure 1.4 Hydrogen storage methods (Rambhujun et al., 2020).

Physisorption-based microporous materials include carbons, zeolites, and metal-organic frameworks (MOFs). They adsorb molecular hydrogen in their porous structures and hydrogen storage capacity depends on the specific surface area. In chemisorption, chemical reactions between metals or alloys with hydrogen provide high theoretical volumetric and gravimetric capacities of 40-120 kgH₂ m⁻³ and 5- 18 wt. % H₂, respectively. Nevertheless, high operating temperature and pressure conditions for de/rehydrogenation, for example, rehydrogenation of LiBH₄ at ~600 °C under 155 bar H₂ for >12 h (He et al., 2019), slow kinetics, and release of by-product gases poisoning fuel cell catalyst, and membranes (e.g., B₂H₆ from LiBH₄ and NH₃ from LiNH₂) (Yan et al., 2012) obstruct the application of hydrides as hydrogen storage materials.

Table 1.1 Targets of material-based automotive hydrogen storage systems set by the US-DOE. (<https://www.energy.gov/eere/fuelcells/doe-technical-targets-onboard-hydrogen-storage-light-duty-vehicles>)

Storage System Targets	Gravimetric density (kg H ₂ /kg system)	Volumetric density (kg H ₂ /L system)	Temperature (°C)	Pressure (bar H ₂)
2025	0.055	0.040	-40-85	5-12
Ultimate	0.065	0.050	-40-85	5-12
Current Status	Gravimetric density (kg H ₂ /kg system)	Volumetric density (kg H ₂ /L system)	Temperature (°C)	Pressure (bar H ₂)
Metal Hydride (MH): NaAlH ₄	12	12	125	0.2-10
Sorbent: MOF-5	38	21	-193	100
Chemical hydrogen (CH) Storage: Off- Board Regenerable (AB)	46	40	-	-

In this work, we aim not only to improve kinetics and hydrogen capacities of hydrides approaching the 2020 US-DOE targets (Table 1.2) (Huang et al., 2021) but also upscaling to hydrogen storage tank. Among several solid-state hydrides, lithium amide (LiNH₂) is one of the most promising materials for reversible hydrogen storages because it contains high theoretical hydrogen content of 8.7 wt. % (Figure 1.5) (Miceli, 2010). However, ammonia (NH₃) released upon decomposition of LiNH₂ (equation (1.1)), toxic to fuel cell catalysts must be suppressed (Yao et al., 2007).

Figure 1.5 Theoretical hydrogen storage capacities of hydrogen storage materials (Miceli, G. (2010)).

To use LiNH₂ as hydrogen storage material, reactive hydride composites (RHCs) between LiNH₂ and other hydrides, such as LiNH₂-MgH₂ (Xilin et al., 2014), LiNH₂-LiAlH₄ (Dolotko et al., 2011), LiNH₂-LiBH₄ (Liu et al., 2009), LiNH₂-MgH₂-LiBH₄ (Wang et al., 2015), and LiNH₂-Ca(BH)₄ (Yua et al., 2011) have been proposed. Among all LiNH₂-based composites, LiNH₂-LiH is one of the best-performing materials for storing hydrogen due to its relatively low operating temperature, good reversibility, and low cost (Fernandez et al., 2013). Nevertheless, partial emission of NH₃ as well as poor kinetics, especially with the enhanced cycling numbers are observed. Thus, this work focuses on kinetic improvement and suppression of NH₃ release of LiNH₂-LiH composite by compaction into the pellets and sandwiching with LiH layer. Moreover, hydrogen storage performance in the small hydrogen storage tank is studied.

CHAPTER II

LITERATURE REVIEW

2.1 Hydrogen storage in metal hydrides

Hydrogen chemisorption in the forms of metal and complex hydrides consists of dissociation of hydrogen molecule, diffusion of hydrogen atoms into interstitial sites of metal and formation of M-H bond (Figure 2.1(A)). Nucleation and growth of hydride will occur under moderate temperatures and pressures following the pressure-composition (PCT) isotherms (Figure 2.1(B)(i)) (Klebanoff, 2016). The PCT curve is the correlation between the equilibrium pressure and the hydrogen storage content at temperature settings. The α -phase region corresponds to the formation of metal hydride at low pressures. The plateau region is in accordance with the equilibrium of α and β phases. Nucleation and growth of the metal hydride refer to β -phase region. The plateau region in the PCT plot indicates the reversible hydrogen content. Considering van't Hoff equation (2.1), enthalpy (ΔH) and entropy (ΔS) of hydride formation can be obtained from slope and y-intercept of the van't Hoff plot (Figure 2.1(B)(ii)).

$$\ln(P_{eq}/P_0) = \frac{\Delta H}{RT} - \frac{\Delta S}{RT} \quad (2.1)$$

Where P_{eq} is the plateau pressure, T is the temperature, P_0 is the reference pressure (1 bar), R is the gas constant ($R = 8.314 \text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$), ΔH and ΔS are the enthalpy and entropy changes, respectively.

The enthalpy of metal hydrides relates to the heat during hydrogen absorption and desorption. To obtain equilibrium pressure (P_{eq}) of 1 bar at 40-150 °C, an operating

temperature of fuel cell, ΔH of 30– 55 kJ/mol with constant ΔS (130 J/mol K) is required (Züttle, 2008).

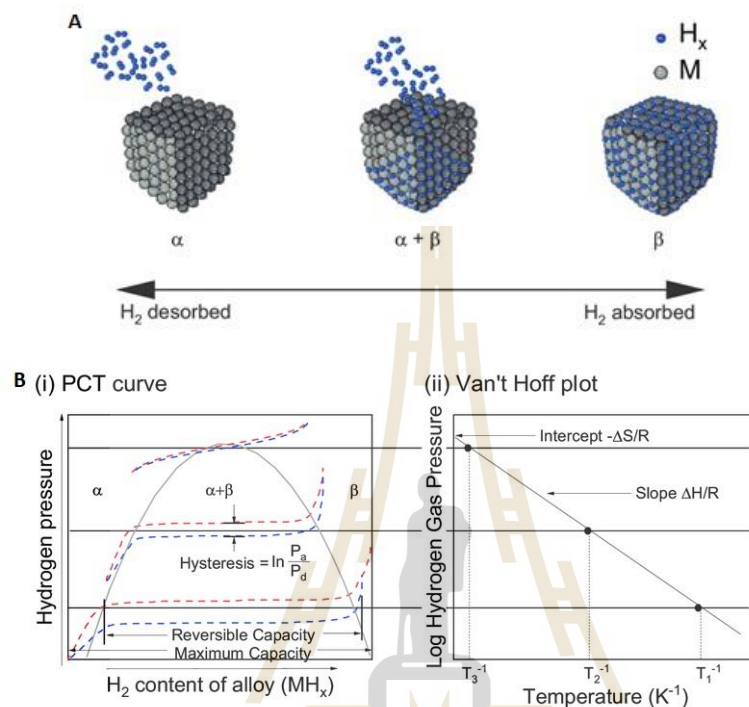

Figure 2.1 Hydride formation (α and β phase) (A), PCT curves (i) and van't Hoff plot (ii) (B) (Modi et al., 2021).

Thus, metal hydrides with high hydrogen capacity and suitable thermodynamic properties are challenging for hydrogen storage materials. Another barrier for the practical application of metal hydrides is kinetic, considering a rate-limiting step for a particular reaction. From Figure 2.2(A), during absorption hydrogen gas is physisorption onto the surface of metal hydride (step 1). Then, hydrogen molecules dissociate into atoms, further occupying and penetrating into the interstitial sites of the host metal (steps 2 and 3). When the amount of hydrogen increases, diffusion through the hydride layer occurs (step 4) to complete hydride formation. For desorption, metal hydride decomposes into metal and hydrogen (step 1). Hydrogen atom diffuses through metal (step 2) and to the surface (step 3). Finally,

the recombination of hydrogen atoms into molecules (step 4), releasing to the environment (step 5).

Figure 2.2 Steps for the absorption (A) and desorption (B) of the metal hydrides. (Jain et al., 2018).

The chemical reaction's activation energy (E_a) presents a barrier in the reaction pathway, in which many hydrides show significantly high E_a . To practically use metal hydride, rapid hydrogen de/rehydrogenation at moderate temperature is needed. Catalytic doping is of interest due to lowering E_a without any changes in chemical structures of reactants and products as well as thermodynamic properties (Züttle, 2008). E_a can be investigated by differential scanning calorimetry (DSC) technique and Kissinger equation (2.2).

$$\ln(\beta/T_p^2) = \frac{-E_a}{RT_p} + \ln(k_0) \quad (2.2)$$

where β is the heating rate ($^{\circ}\text{C}/\text{min}$), T_p is the peak desorption temperature, R is the gas constant ($8.314 \text{ J mol}^{-1} \text{ K}^{-1}$), E_a is the activation energy, and k_0 is a constant.

2.2 LiNH₂/Li₂NH and their tuning strategies

Although other metal hydrides and/or complex hydrides following Figure 1.5 have accomplished high gravimetric and volumetric hydrogen capacities, their dehydrogenation temperatures are still high due to the large enthalpy. LiNH₂/Li₂NH system is one of the most competitive materials for hydrogen storage because of their suitable gravimetric and volumetric capacities according to the U.S. (DOE) (5.5 wt. % and 40 gH₂/L, respectively) (Partnership., 2017). LiNH₂ consists of Li⁺ cation and NH₂⁻ anionic group with tetragonal by space group of *I-4*, which preferred an anti-fluorite with the arrangement of Li in a tetrahedral hole and N in a cubic close-packed. However, LiNH₂ decomposes into Li₂NH and NH₃ at 373-375 °C under vacuum (equation (2.3)) instead of hydrogen. Thus, LiNH₂-LiH composite has been proposed, which the obtained NH₃ further reacts with LiH to form Li₂NH and H₂ (equation (2.4)). However, the deterioration of LiH due to hydrolysis/oxidation led to NH₃ emission, resulting in poisoning proton exchange membranes (PEMFCs) and poor hydrogen capacity (Shaw et al., 2008). Moreover, poor kinetics due to slow NH₃ diffusion through the Li₂NH coated on the LiNH₂ core and deficient interfaces between LiH and NH₃ are serious issues (Chen et al., 2002). Regarding the previous work reported by Chen et al. (2003) and Chen et al. (2002), overall reaction for LiNH₂-LiH decomposition (equation (2.5)) provides the storage capacity of 6.5 wt. % H₂.

For Li₂NH, it has two crystal structures of *Fm-3m* and *Imma* space group as low-temperature (LT) and high-temperature (HT) phases, respectively (Juza, 1951). Phase transition of Li₂NH from the LT to the HT can be detected at 400-500 K. During the decomposition of LiNH₂, the rate-limiting step is NH₃ formation at the interface of LiNH₂/Li₂NH (Figure 2.3).

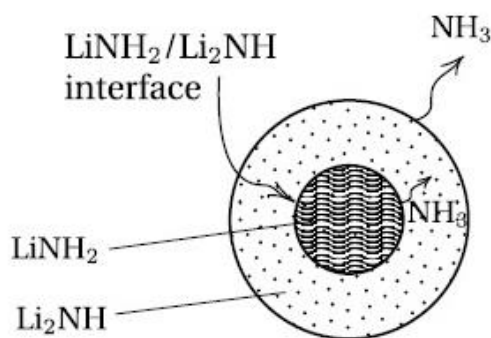

Figure 2.3 The decomposition path of the $\text{LiNH}_2/\text{Li}_2\text{NH}$ (Miceli et al., 2010).

Several approaches to improve de/rehydrogenation kinetics and suppress NH_3 emission of $\text{LiNH}_2\text{-LiH}$ composites, including nanoparticle preparation and catalytic doping have been reported. Varin et al. (2010) studied the effects of milling time and $\text{LiNH}_2\text{:LiH}$ molar ratio. When the milling time increased up to 25 h, the grain size of $\text{LiNH}_2\text{-LiH}$ composite decreased, enhancing specific surface area. (Figure 2.4(A)).

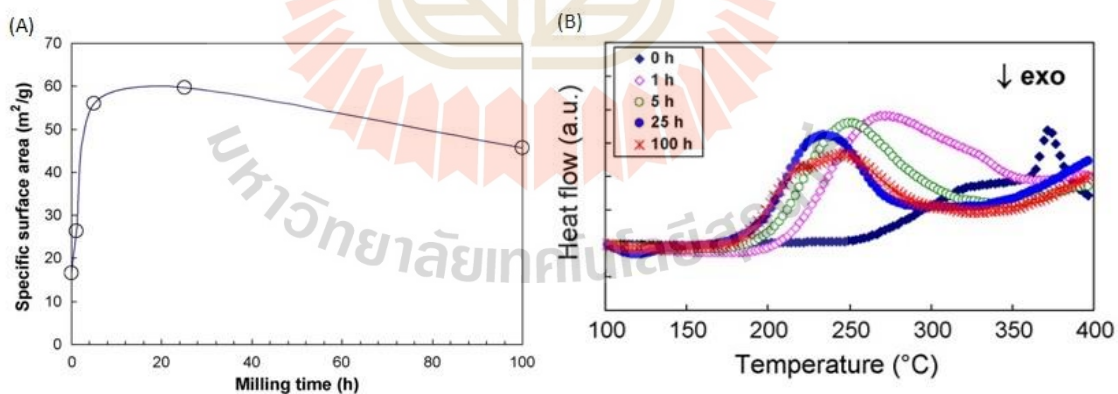

Figure 2.4 The specific surface area to ball milling time of the $\text{LiNH}_2\text{-LiH}$ composite (A) and DSC profiles for varied milling time (B).

Dehydrogenation temperature decreased with the increase of milling time up to 25 h (Figure 2.4(B)). From Table 2.1, not only milling time but also the enhancement of LiH content benefits dehydrogenation kinetics.

Table 2.1 Summary of the DSC profiles for $\text{LiNH}_2\text{-LiH}$ by varied milling time and LiH molar ratio.

Milling time (h)	Molar ratio	DSC peak ($^{\circ}\text{C}$)	
	($\text{LiNH}_2\text{-LiH}$)	T (onset)	T (main)
0	1:1	268	324.7
1	1:1	212	272.5
5	1:1	196.2	250.2
25	1:1	186	235.2
25	1:1.2	183.4	239.2
25	1:1.4	180.3	234.1
100	1:1	187.2	245

When the milling time increased, the onset temperature decreases from $268\text{ }^{\circ}\text{C}$ to $180\text{ }^{\circ}\text{C}$ because most LiNH_2 could effectively react with LiH. The latter was explained by good contact between LiNH_2 and LiH particles. In the case of LiNH_2 : LiH mole ratios increasing from 1:1 to 1:1.4, onset desorption temperature decreased because of excess LiH overcoming hydrolysis/oxidation into LiOH or Li_2O .

Furthermore, various additives and/or catalysts, such as metal hydrides (LiH, NaH, KH, MgH_2 , CaH_2 , and TiH_2 (Amica et al., 2015), graphite (Varin et al., 2011), nitrides, and Ti-Li-N compounds (TiN , BN and Li_5TiN_3 (Aguay-Zinsou et al., 2007), (Nayebossadri et al., 2011), (Du et al., 2015), halides (AlCl_3 (Fernández Albanesi et al., 2013), MgCl_2 (Davies et al., 2015), CeF_4

(Lin et al., 2018), KF (Dong et al., 2016), RbF (Dong et al., 2017), amide KNH_2 (Ping et al., 2019), and oxides (LiOH , NaOH , KOH (Dong et al., 2015), and LiTi_2O_4 (Zhang et al., 2015)) have been studied to improve hydrogen sorption properties of LiNH_2 - LiH composite. Amica et al. (2015) studied chemical interactions during hydrogen cycling of LiNH_2 - 1.6LiH doped with MH_2 ($M = \text{Mg}$, Ca , Ti). The results showed that LiNH_2 doped with MgH_2 and CaH_2 produced the solid solutions of $\text{Li}_2\text{Mg}(\text{NH})_2$ and $\text{CaNH-Ca}(\text{NH}_2)_2$, revealing superior de/rehydrogenation kinetics (Figure 2.5). However, TiH_2 showed poorer kinetics with respect to MgH_2 - and CaH_2 - doped samples. This can be explained by the fact that TiH_2 presented direct contact with LiNH_2 and LiH , whereas MgH_2 and CaH_2 interacted with LiNH_2 . Furthermore, Dong et al. (2016) reported the positive effects of potassium fluoride (KF) on the LiNH_2 - LiH composite, in which the cycling stability of LiNH_2 - LiH was enhanced after doping with KF (Figure 2.6).

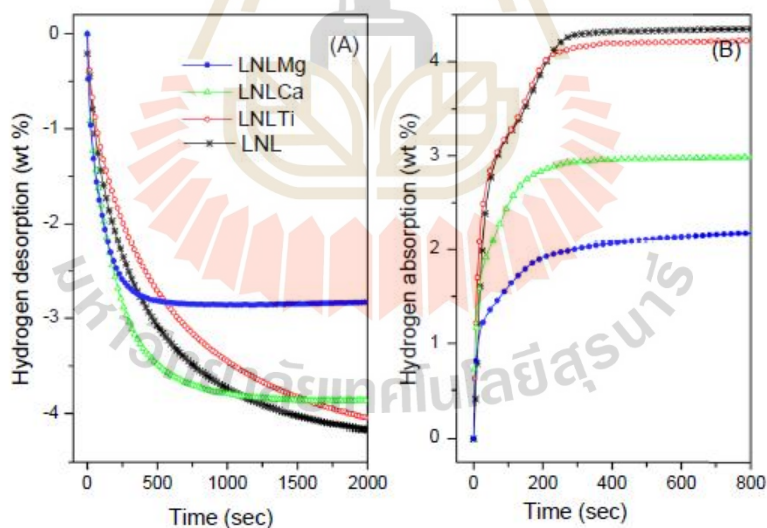

Figure 2.5 Dehydrogenation under 0.02 MPa (A) and rehydrogenation under 0.7 MPa hydrogen pressure (B) at 300 °C of the LiNH_2 - 1.6LiH and doping with MH_2 ($M = \text{Mg}$, Ca , and Ti).

Potassium hydride (KH) formed during ball milling of $\text{LiNH}_2\text{-LiH}$ doped with KF acted as active species to improve hydrogen storage properties since it could react with NH_3 to produce KNH_2 and release hydrogen (equation 2.6).

Lin et al. (2018) reported kinetic improvement of the $\text{LiNH}_2\text{-LiH}$ system with 10 wt. % cerium-based materials (Ce , CeO_2 , CeF_3 , and CeF_4) (Figure 2.7).

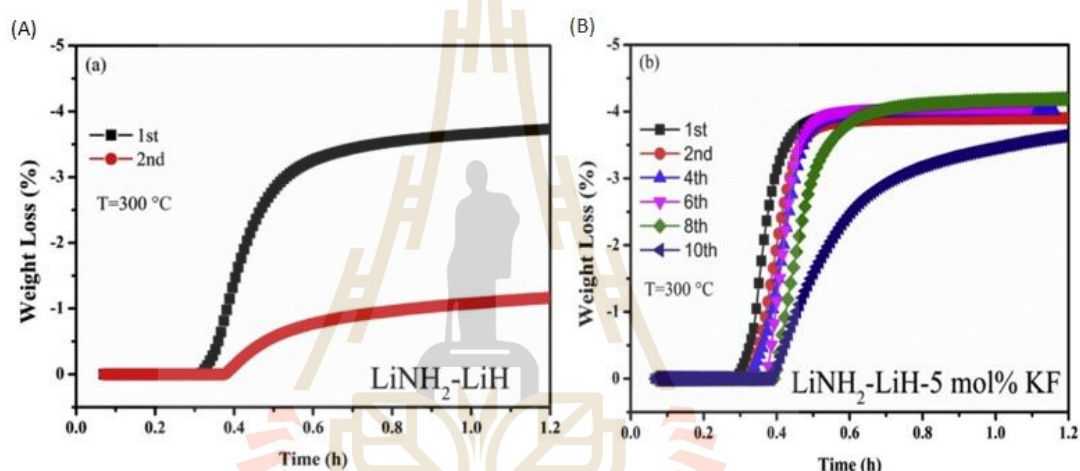

Figure 2.6 Cycling stability of $\text{LiNH}_2\text{-LiH}$ (A) and $\text{LiNH}_2\text{-LiH-5mol%KF}$ (B).

The best kinetic improvement and suppression of NH_3 emission was obtained from the sample doped with CeF_4 . It was found that CeF_x species formed during the ball milling process was a good catalyst for LiNH_2 decomposition without NH_3 emission. Moreover, some active intermediate of Li_5TiN_3 found after ball milling of $\text{LiNH}_2\text{-LiH-Ti}$ -based compounds (e.g., Ti , TiCl_3 , and TiO_2) acted as NH_3 carriers from LiNH_2 to LiH on a nanometer scale in the forms of $\text{Li}_5\text{TiN}_3(\text{NH}_3)_x$ (Teng et al., 2011).

For carbon materials, Varin et al. (2011) proposed that doping graphite (5 wt. %) into $\text{LiNH}_2\text{-LiH}$ showed an increase in the de/absorbed capacities at 325 °C from 4.7 to

5.2 wt. % H_2 as well as superior reversibility with 5 wt. % H_2 . It was suggested that graphite could prevent or reduce the oxidation/hydrolysis of LiH due to the water repelling from its surface. Moreover, hydrogen diffusion and heat transfer of hydride materials could be enhanced by several carbon materials, such as multi-walled carbon nanotubes (MWCNTs), activated carbon, graphene, and carbon nanofibers (CNFs).

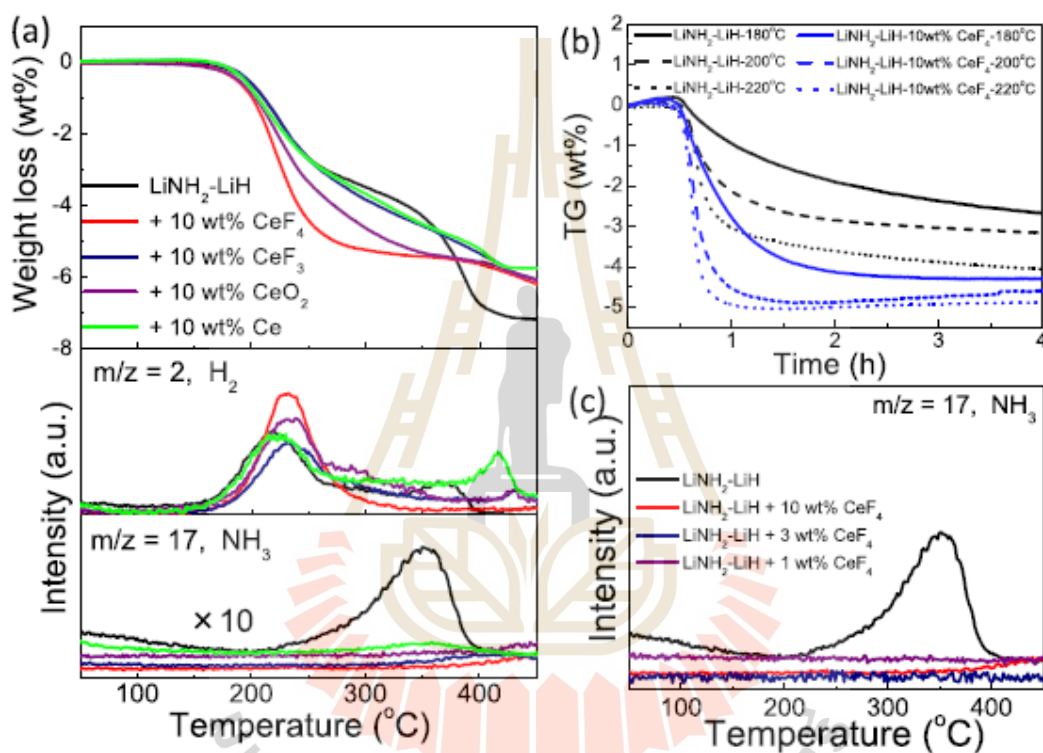

Figure 2.7 Dehydrogenation profiles of the $LiNH_2-LiH$ composites and Ce -doped $LiNH_2-LiH$ (a), Isothermal dehydrogenation of the $LiNH_2-LiH$ composites and CeF_4 -doped $LiNH_2-LiH$ at different temperatures (b), and NH_3 signal in MS curves of CeF_4 -doped $LiNH_2-LiH$ (c).

2.3 Small hydrogen storage tanks for hydrogen storage materials

In practical applications, the hydride materials have to be packed into a closed tank. Experimental and numerical works have investigated the hydrogen sorption properties of the storage tanks. Chaise et al. (2010) and Chung et al. (2013) studied both experimental and numerical data on the de/rehydrogenation properties of the magnesium hydride-based hydrogen storage tank. They reported the enhancement of the hydrogen sorption rate by inserting heat pipes into a novel metal hydride tank. Also, heat transfer properties affecting hydrogen sorption properties were improved by inserting a heat exchanger (Wu et al., 2014). Besides tube heat exchanger, the thermal conductivity of hydride tanks was enhanced by integrating copper wire nets, aluminum foams, and hydride-graphite composites (Shim et al., 2014), (Mazzucco et al., 2014). Furthermore, the volumetric hydrogen storage capacities for hydrogen storage tanks can be enhanced by compacting metal hydride to the pellet (Lozano et al., 2011). Recently, Yan et al. (2015) designed a cylindrical lab-scale tank based on compaction of $\text{Mg}(\text{NH}_2)_2\text{-2LiH-0.07KOH}$ mixed with expanded natural graphite (ENG). The laboratory-scale hydrogen storage tank was designed with 205 mm and 32 mm of length and diameter, respectively. There was a porous filter tube placed in the tank center for the hydrogen diffusion pathway. In addition, three thermocouples were located in the hydride beds for measuring the temperature during de/rehydrogenation (Figure 2.8(A)). Dehydrogenation kinetics of the compacted $\text{Mg}(\text{NH}_2)_2\text{-2LiH-0.07KOH}$ mixed with up to 17 wt.% ENG were operated at 220 °C with a hydrogen flow rate of 0.6 L/min. Three regions (I, II, and III) during hydrogenation were characterized (Figure 2.8(B)). In region I, hydrogen pressure rapidly decreases and the temperature of the hydride bed is reduced when desorption occurs. For region II, the temperature decreases continuously together with hydrogen pressure drops due to the decomposition of hydrogen storage materials. The mass flow controller demonstrates hydrogen gas flows through with a constant flow rate until the pressure drops due to complete dehydrogenation.

Finally, region III is the hydrogen desorption almost finishes shown as the reduction of hydrogen flow rate less than 0.1 L/min, and the temperature in the tank increases to the set-point temperature.

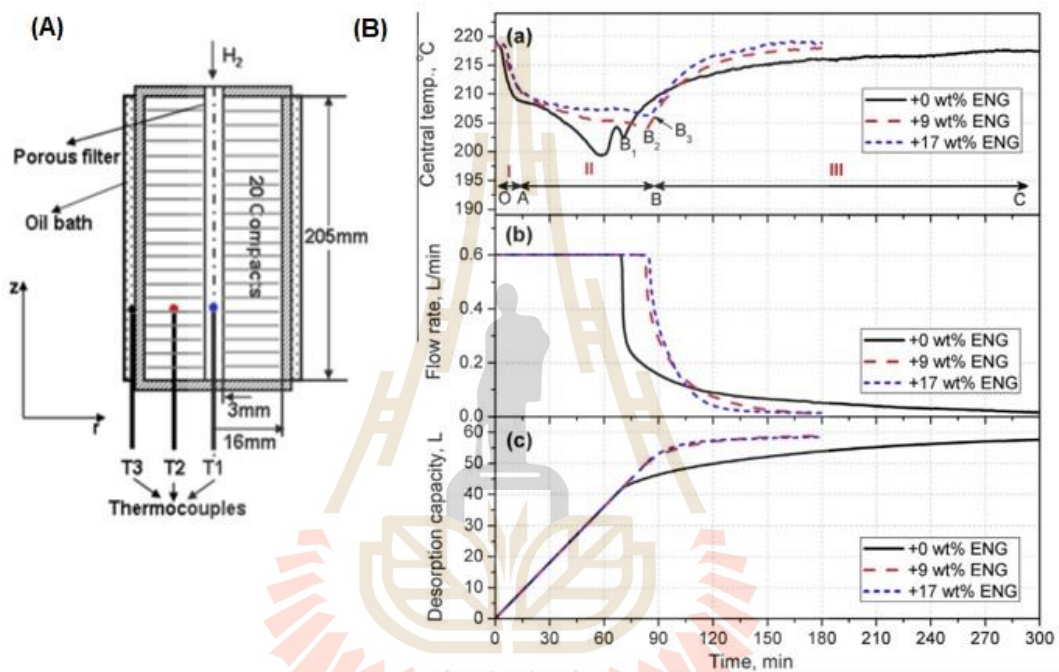

Figure 2.8 Laboratory-scale hydrogen storage tank (A) and Hydrogen desorption graph of compacted $\text{Mg}(\text{NH}_2)_2\text{-}2\text{LiH}\text{-}0.07\text{KOH}$ with different ENG contents (B).

From Figure 2.8, when ENG is added in the hydride-based tank, the diffusion pathway and heat transfer of the hydride enhance. The latter results in an improvement of the hydrogen desorption process of the tank.

To the best of our knowledge, there have been no studies on the upscaling of $\text{LiNH}_2\text{-LiH}$ to hydrogen storage tanks. In this study, the powder samples of $\text{LiNH}_2\text{-LiH}$ will be compacted into the pellets prior to packing into the small tank to increase volumetric hydrogen capacity. However, high compaction pressure results in poor hydrogen diffusion and poor de/rehydrogenation kinetics and reversibility. Thus, catalysts and/or additives of titanium-based catalysts (TiF_4) and multi-walled carbon nanotubes (MWCNTs) will be added into $\text{LiNH}_2\text{-LiH}$. De/rehydrogenation kinetics of compacted $\text{LiNH}_2\text{-LiH}$ is favored by the catalytic properties of TiF_4 as well as the improved hydrogen diffusion and thermal properties from MWCNTs (Plerdsranoy et al., 2017).

CHAPTER III

EXPERIMENTAL SECTION

3.1 Chemicals

Table 3.1 Chemicals used in this work.

Chemicals	Formular	specification	Supplier
Lithium amide	LiNH_2	95 %	Aldrich
Lithium hydride	LiH	95 %	Aldrich
Titanium tetrafluoride	TiF_4	99 %	Acros Organics
Multiwall carbon nanotubes	MWCNTs	-	diameter of 20-50 nm, Nano Materials Research Unit

3.2 Apparatus

3.2.1 Glovebox and high-energy ball milling

Due to the sensitivity of hydride materials to air and moisture, all samples were handled under a nitrogen atmosphere in the glove box (Figure 3.1(A)). The ball milling was used for sample preparation (Figure 3.1(B)).

Figure 3.1 Glove box (Omni-Lab System, VAC) (A) and A QM0.4L Planetary Ball Mill, Nanjing Chishun Science & Technology (B).

3.3 Sample preparation

3.3.1 Compacted $\text{LiNH}_2\text{-LiH}$ doped with TiF_4 and MWCNTs

LiNH_2 was mixed with LiH by 1:1 molar ratio and milled for 5 h and 10 h with a ball-to-powder weight ratio of 20:1 and 580 rpm, respectively, to obtain $\text{LiNH}_2\text{-LiH}$ composites, denoted as LNL. LNL composite (5 h) was milled with 5.0 wt.% TiF_4 for 5 h and with MWCNTs for 10 min. The powder samples of LNL (10h) and LNL- TiF_4 -MWCNTs were compressed into the pellets under 200 Mpa using a pellet die set with 15 mm diameter to obtain the compacted samples of LNL and LNL- TiF_4 -MWCNTs, respectively. The densities of the LNL and LNL- TiF_4 -CNT pellets were ~ 0.7 and 1.00 g/cm^3 , respectively.

3.3.2 LiH-sandwiched $\text{LiNH}_2\text{-LiH-TiF}_4\text{-MWCNTs}$ pellets

LiH was pre-milled for 5 h and milled with 1 wt. % MWCNTs for 30 min. The powder sample of LNL (5h) obtained from 3.3.1 was sandwiched between MWCNTs-doped LiH by compressing under 200 MPa to obtain LiH-sandwiched LNL (Figure 3.2(A)). The amounts of MWCNTs-doped LiH layers were 10, 20, and 30 wt. % with respect to LNL content, and the obtained pellet samples were named LNL- 10% LiH, LNL-20% LiH, and LNL-30% LiH, respectively.

3.4 Small hydrogen storage tanks containing compacted LNL, LNL- TiF_4 -MWCNTs and LiH-sandwiched LNL

All compacted samples ($\sim 2\text{-}3 \text{ g}$) were packed into separated cylindrical tanks with a packing volume of 21.7 mL (Figure 3.2(B-D)). Hydrogen diffusion inside the tank was improved by inserting the stainless-steel (SS) mesh sheets between the compacted pellets. Temperature profiles inside the tank were investigated using K-type thermocouples from SL heater (TC1, TC2, and TC3 inserted at the depths of 3, 2, and 1 cm, respectively) (Figure 3.2(C-D)).

Figure 3.2 Schematic draw of LiH-sandwiched LNL pellet (A), the components of small hydrogen storage tank (B), and the positions of thermocouples along the tank length packed with compacted samples of LNL and LNL-TiF₄-MWCNTs (C) and LiH-sandwiched LNL (D).

3.5 Characterizations

3.5.1 Chemical compositions and structure

3.5.1.1 Powder x-ray diffraction (PXD)

Powder x-ray diffraction (PXD) experiments were done using a Bruker D8 ADVANCE with Cu K α source ($\lambda = 0.15406$ nm). The pellet sample was ground and packed in the sample holder covered with a poly (methylmethacrylate)(PMMA) dome (Figure 3.3) under a nitrogen-filled glove box. The experiments were investigated at the 2θ range and the scanning step of $10\text{--}80^\circ$ and $0.02^\circ/\text{s}$, respectively.

Figure 3.3 An airtight sample holder covered with a PMMA dome.

3.5.1.2 Fourier transform infrared spectroscopy (FTIR)

Fourier transform infrared spectroscopy (FTIR) spectra were collected using an attenuated total reflection (ATR) mode (a Bruker T27/Hyp 2000) in 4000-400 cm^{-1} wavenumber range with 64 scans (Figure 3.4).

Figure 3.4 FTIR spectrometer of Tensor 27-Hyperion 2000 (Bruker).

3.5.1.3 X-ray photoelectron spectroscopy (XPS)

X-ray photoelectron spectroscopy (XPS) experiments were carried out at the Suranaree University of Technology (SUT), National Nanotechnology Center (NANOTEC) and Synchrotron Light Research Institute (SLRI) joint research facility, Synchrotron Light Research Institute (Public organization), Thailand (Figure 3.5). A PHI5000 Versa Probe II (ULVAC-PHI Inc., Japan) with Al $K\alpha$ (1.486 keV) radiation as an excitation source was used. The powder samples were deposited on the sample holder using carbon glue tape in the glove box. Prior to the measurements, the samples were placed in the high vacuum chamber (1×10^{-8} mbar) for 2 h. The high-resolution scan of each element was collected using a pass energy of 46.95 eV and a step size of 0.05 eV. Dual-beam charge neutralization (low energy electron and ion beam) method was used to minimize sample charging. The binding energy was calibrated with respect to the C 1s peak (284.8 eV).

The data was analyzed using MultiPak software version 9.6.0 (ULVAC-PHI, Japan). Peak fitting was performed after Shirley background subtraction. The symmetrical Gaussian-Lorentzian function was used to approximate the line shapes of the fitting components.

Figure 3.5 X-ray photoelectron spectroscopy at Suranaree University of Technology (SUT), National Nanotechnology Center (NANOTEC) and Synchrotron Light Research Institute (SLRI).

3.5.2 Hydrogen sorption properties

3.5.2.1 Simultaneous thermal analysis (STA) coupled with mass spectroscopy (MS)

Hydrogen desorption was characterized by differential scanning calorimetry (DSC) and thermogravimetry (TG) using a Netzsch (STA 449 F3 Jupiter) (Figure 3.8). The sample (~15 mg) was heated to 500 °C (5 °C/min) under 50 mL N₂/min. The relative signals of H₂ and NH₃ released from the sample were investigated by mass spectroscopy (MS) using a Netzsch QMS 403C (Figure 3.6).

Figure 3.6 STA 449 F3 Jupiter coupled with QMS 403C (Netzsch).

3.5.2.2 Sievert-type apparatus for tank scale

Titration measurements were carried out using a test station automatically controlled by a program created in the Labview® environment (Dansirima et al., 2019), (Thiangviriyaya et al., 2019), (Thongtan et al., 2018). The small hydrogen storage tanks packed with the compacted samples were assembled with other components of the sample holders for titration measurement (Figure 3.7). The direct-acting plunger solenoid valves (a Bürkert Type 0255) were used to control hydrogen consumption and liberation during de/rehydrogenation. The pressure change during the experiments was detected by a pressure transducer (0–3000 psig, an OMEGA Engineering PX309–3KGI). Temperature, pressure, and mass flow rate profiles were transferred to the computer using the module data loggers (a National Instruments NI USB-6009 and a Wisco AI210). Hydrogenation was carried out at isothermal conditions ($T_{\text{set}} = 330 \text{ }^{\circ}\text{C}$) under 10–15 bar H_2 . Dehydrogenation was at $T_{\text{set}} = 330 \text{ }^{\circ}\text{C}$ and began with the hydrogen pressure of 15 bar, remaining after hydrogenation. A mass flow controller (MFC, a Bronkhorst EL-FLOW selected F-201CV) with the operating range of 0–1.0 standard L/min (SLM) was used to measure the content of hydrogen desorbed.

The volume of hydrogen gas was achieved by integrating the peak area of hydrogen mass flow rate (SLM) versus time (min) plot. Total hydrogen storage capacity, defined as the combination of material hydrogen capacity and hydrogen content remaining after absorption was calculated as following equations.

$$V_{STP} = \frac{P_s V_s T_{STP}}{T_s P_{STP}} \quad (3.1)$$

$$n_{H_2} = \frac{V_{STP}}{22.4 \text{ L} \cdot \text{mol}^{-1}} \quad (3.2)$$

$$H_2 \text{ capacity (wt. \%)} = \frac{n_{H_2} \times 2.016 \text{ g/mol}}{\text{sample weight (g)}} \times 100 \quad (3.3)$$

where V_{STP} (L) and V_s (SL) are volumes of hydrogen gas at standard temperature and pressure condition (STP, $T_{STP} = 273.15 \text{ K}$ and $P_{STP} = 1.0133 \text{ bar}$) and at the standard condition of MFC ($T_s = 296.15 \text{ K}$ and $P_s = 1.0156 \text{ bar}$), respectively. n_{H_2} (mol) is hydrogen mole and standard molar volume is 22.4 L/mol .

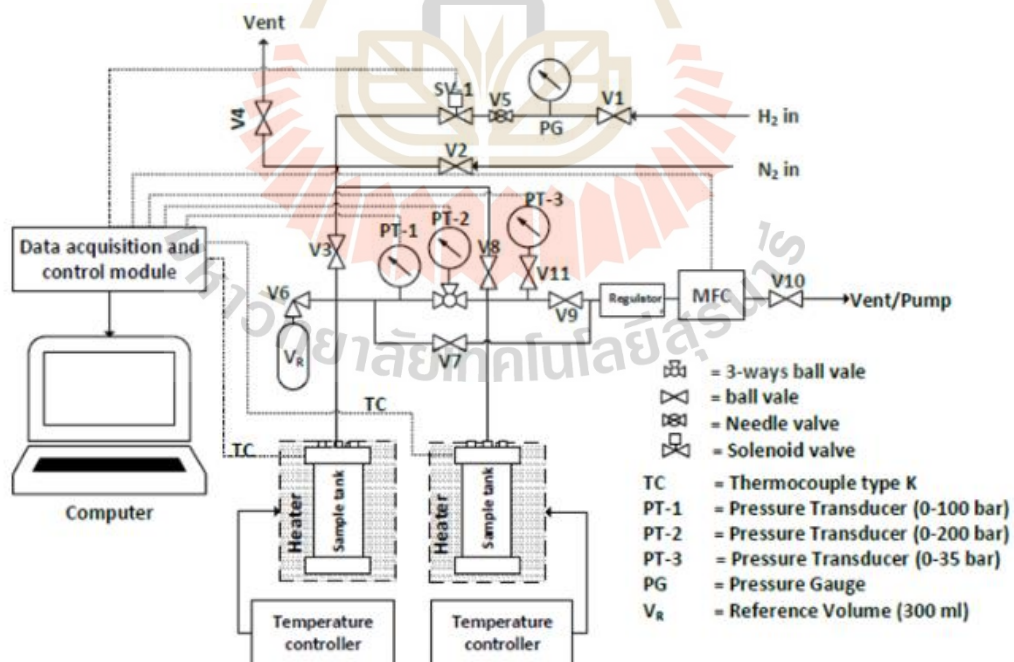

Figure 3.7 Schematic diagram of Sievert-type apparatus.

CHAPTER IV

RESULTS AND DISCUSSION

4.1 Compacted $\text{LiNH}_2\text{-LiH}$ doped with TiF_4 and MWCNTs

Dehydrogenation of compacted samples is characterized by the simultaneous DSC-TG-MS technique. Compacted LNL shows two-step decomposition at 246 and 416 °C corresponding to H_2 -MS signals and storage capacities of 1.7 and 4.1 wt. % H_2 , respectively (Figure 4.1(A)).

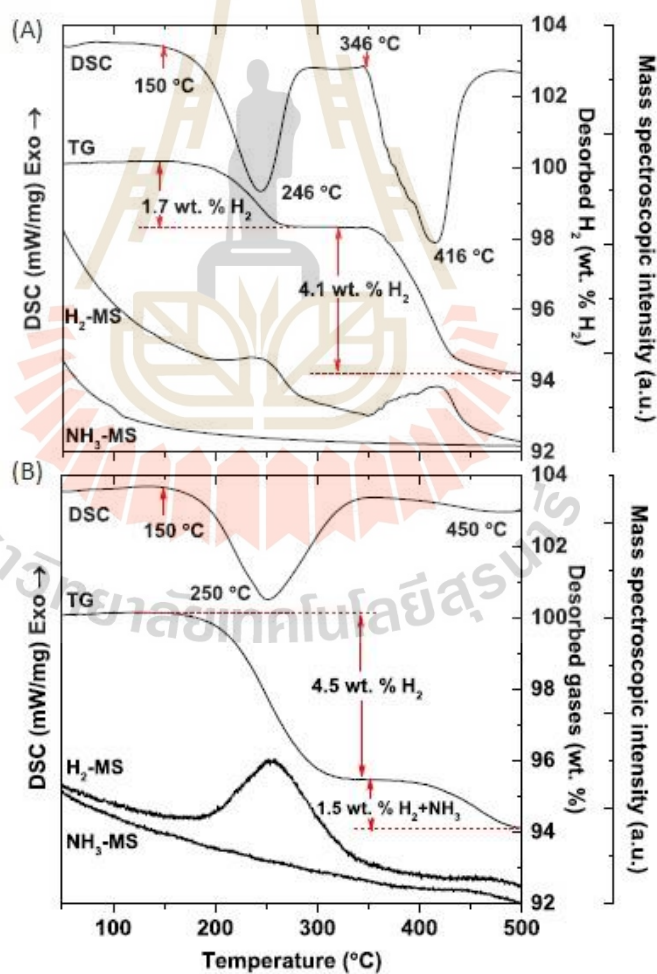

Figure 4.1 Simultaneous DSC-TG-MS results during dehydrogenation of LNL (A) and LNL- TiF_4 -CNT (B).

From the previous reports, the decomposition of $\text{LiNH}_2\text{-LiH}$ presents at 150-450 °C with NH_3 release at $T > 300$ °C, indicating a slow decomposition rate of LiNH_2 and deficient interface of NH_3 and LiH to produce Li_2NH and H_2 (Nayebossadri et al., 2011), (Dong et al., 2015), (Fernandez Albanesi et al., 2013). In this study, compacted LNL dehydrogenated at 150-450 °C without NH_3 release. This is because high compaction pressure results in a slow decomposition rate of LiNH_2 and poor NH_3 diffusion. In the case of compacted LNL- $\text{TiF}_4\text{-CNT}$, a single-step reaction shows onset and main dehydrogenation temperatures at 150 and 250 °C, respectively, with H_2 capacity of 4.5 wt. % (Figure 4.1.(B)). The theoretical capacity of LNL- $\text{TiF}_4\text{-CNT}$ is 5.85 wt. % H_2 according to TiF_4 and MWCNTs loading contents (10 wt. %) and the theoretical capacity of $\text{LiNH}_2\text{-LiH}$ (6.5 wt. % H_2). By doping with TiF_4 and MWCNTs, hydrogen content liberating from compacted $\text{LiNH}_2\text{-LiH}$ at ~ 350 °C increases from 1.7 to 4.5 wt. % H_2 (26-77% of theoretical capacity) (Figure 4.1). Kinetic improvement can be described by the catalytic effect of TiF_4 and the enhanced hydrogen diffusion and thermal conductivity from MWCNTs (Thiangviriyā et al., 2019). However, the increase of hydrogen permeability probably favors NH_3 diffusion as observed in signals of hydrogen and NH_3 (1.5 wt. %) at $T > 400$ °C during dehydrogenation of compacted LNL- $\text{TiF}_4\text{-CNT}$ (Figure 4.1(B)).

Furthermore, de/rehydrogenation kinetics of these samples are investigated. Due to the signal of NH_3 detected at $T > 400$ °C from compacted LNL- $\text{TiF}_4\text{-CNT}$ (Figure 4.1(B)), hydrogen desorption and absorption are carried out under isothermal at setting temperature (T_{set}) of ~ 335 °C to avoid NH_3 release. As-prepared pellets are heated from room temperature to T_{set} under hydrogen pressure of ~ 20 bar to prevent dehydrogenation. When an isothermal condition is obtained, hydrogen gas is liberated from the tank with constant flow rate of 50 standard cc/min (sccm). When dehydrogenation starts, sample temperatures reduce due to endothermic reaction. Dehydrogenation of compacted LNL tank begins at $t \sim 6$ min under the system pressure (P_{sys}) of 7.5 bar H_2 (Figure 4.2).

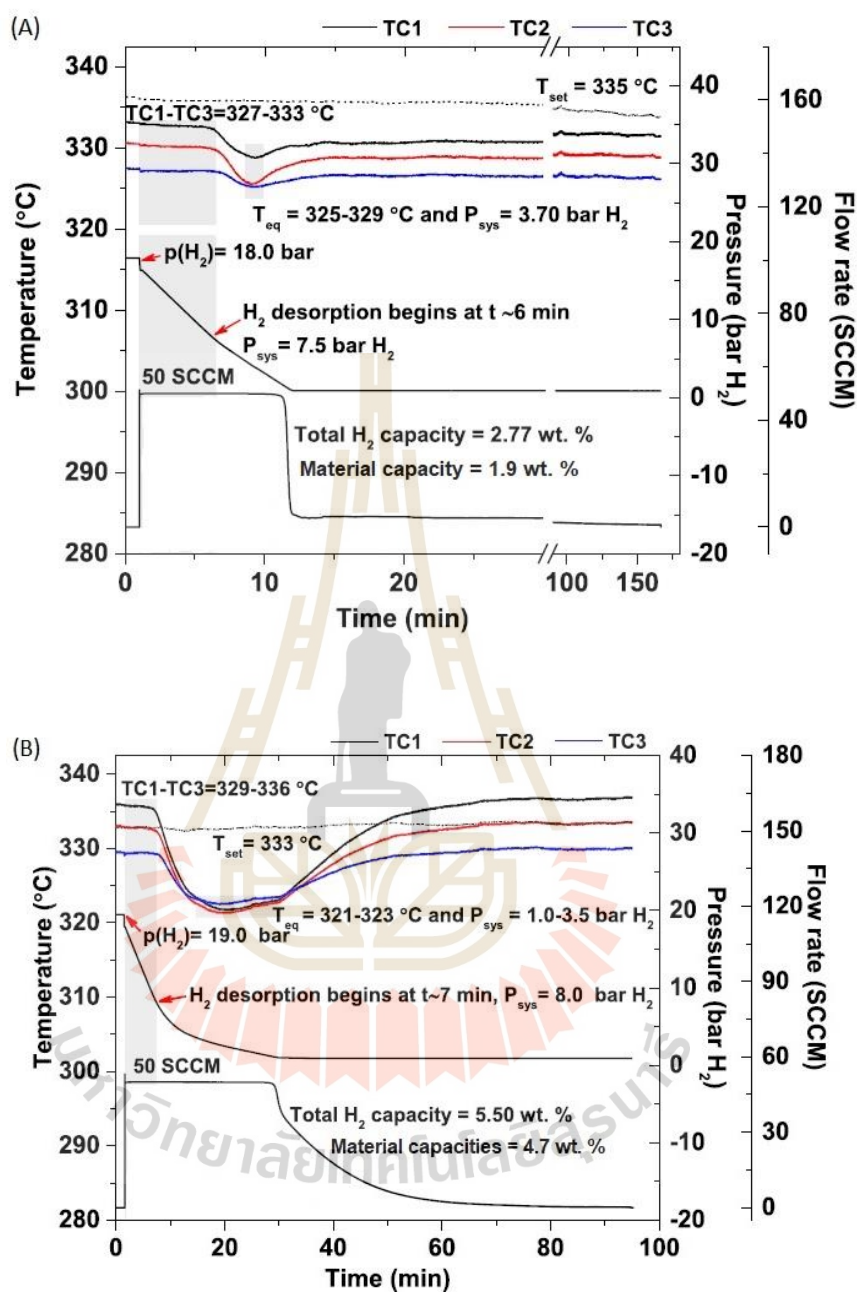

Figure 4.2 Temperature, pressure, and hydrogen flow rate profiles during dehydrogenation of small hydrogen storage tanks containing compacted LNL (A) and LNL-TiF₄-CNT (B).

Complete dehydrogenation is obtained with total and material storage capacities of 2.77 and 1.9 wt. % H₂, respectively. The obtained material capacity corresponds to 1.7 wt % H₂ released from the compacted LNL at T < 300 °C detected by simultaneous DSC-TG-MS result (Figure 4.1(A)). For compacted LNL-TiF₄-CNT tank, dehydrogenation starts at t~7 min under P_{sys} of 8.0 bar H₂ (Figure 4.2(B)). Long plateau range (~20 min) with a constant hydrogen flow rate (50 sccm) up to 30 min confirm effective desorption. Total and material hydrogen capacities of 5.50 and 4.70 wt.% H₂, respectively, agree with simultaneous DSC-TG-MS results (4.5 wt. % H₂) (Figure 4.1(B)). Therefore, the dehydrogenation kinetics of compacted was improved due to both catalytic effects of TiF₄ and hydrogen diffusion from MWCNTs. Rehydrogenation is continuously performed at isothermal conditions (T_{set} = 333-334 °C) under 10-20 bar H₂. When hydrogen pressure is applied to the storage tank, temperatures rise rapidly to equilibrium temperatures (T_{eq}) of 334-347 and 359-395 °C, in agreement with equilibrium pressure (P_{eq}) of 3.5-5 and 7-8.5 bar H₂ of compacted LNL and LNL-TiF₄-CNT tanks, respectively (Luo et al., 2005) (Figure 4.3).

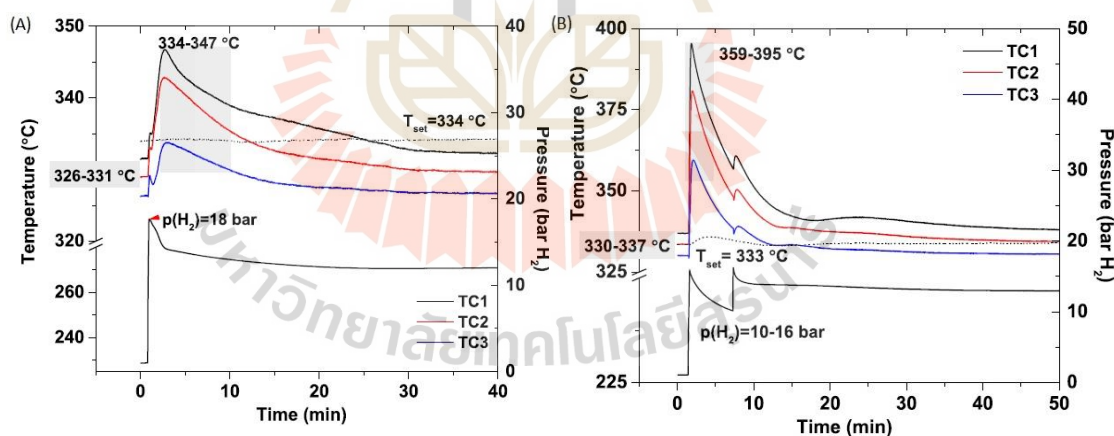

Figure 4.3 Temperature and pressure profiles during rehydrogenation of small hydrogen storage tanks containing compacted samples of LNL (A) and LNL-TiF₄-CNT (B).

P_{eq} of compacted LNL-TiF₄-CNT is greater than that of compacted LNL and approaches the applied pressure (10-16 bar H₂), indicating superior hydrogen diffusion (Figure 4.3 (B)). The anisotropic alignment of MWCNTs in compacted LNL-TiF₄-CNT might provide

transporting channels for hydrogen in all directions of the compacted samples. The latter favors hydrogen diffusion during desorption rather than absorption due to hydrogen being applied from only one direction (top of the tank). In addition, initial temperatures at all positions (326-331 °C) in compacted LNL tank are lower than T_{set} (334 °C) (Figure 4.3(A)), whereas those of compacted LNL-TiF₄-CNT tank (330-337 °C) are comparable to T_{set} (333°C) (Figure 4.3(B)). These results confirm superior thermal conductivity of compacted LNL-TiF₄-CNT tank. Complete rehydrogenation of both tanks is confirmed by the reduction of temperatures to the initial values within 30 min.

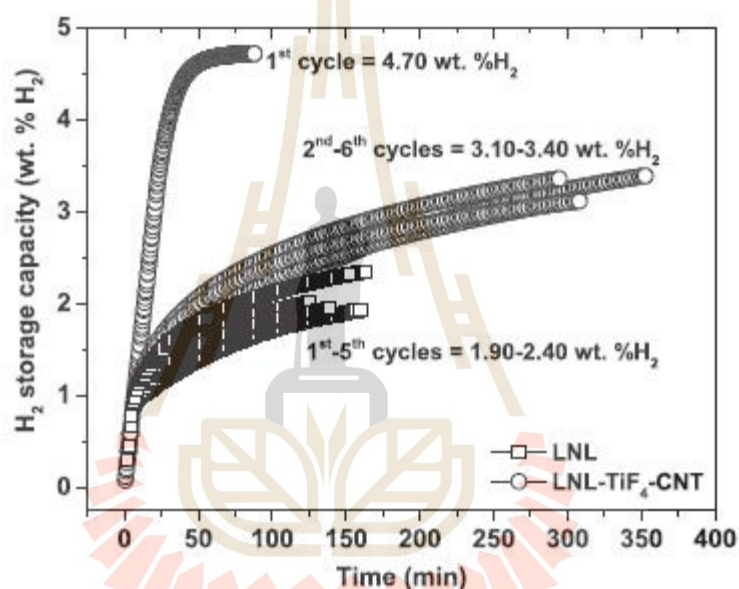

Figure 4.4 Dehydrogenation kinetics and reversibility during cycling of small hydrogen storage tanks containing compacted LNL and LNL-TiF₄-CNT.

Furthermore, kinetics and reversibility of compacted LNL and LNL-TiF₄-CNT tanks are evaluated. From Figure 4.4, (1.90-2.40 wt. % H₂ or 29-37% of theoretical value) are achieved from compacted LNL tank upon five hydrogen de/rehydrogenation cycles. In the case of compacted LNL-TiF₄-CNT tank, 4.70 wt. % H₂ is obtained within 100 min during the 1st cycle. However, the hydrogen capacities reduce to 3.10-3.40 wt. % H₂ (53-58% of theoretical value) with slower kinetics during the 2nd-6th cycles. Nevertheless, reversible hydrogen capacity increases from 37 to 58% of theoretical values after doping with TiF₄ and MWCNTs.

Reaction mechanisms during de/rehydrogenation of both tanks are studied by PXD and FTIR techniques. From Figure 4.5(a), as-prepared LNL reveals diffraction patterns of LiNH_2 and LiH , implying no reaction between hydride materials during ball milling. Upon cycling (the 1st- 2nd de/rehydrogenation), diffraction patterns of LiNH_2 , Li_2NH , LiH , and Li_2O are observed (Figure 4.5(b-d)). For FTIR results, all samples show vibrational peaks of LiNH_2 at 3314 and 3259 cm^{-1} , while de/rehydrogenated pellets show the signal of Li_2NH at 3252 and 3184 cm^{-1} , corresponding to asymmetric and symmetric stretching of N-H bonds, respectively (Figure 4.6(a-d)) (Kojima et al., 2005). The signals of LiNH_2 , Li_2NH , and LiH detected in de/rehydrogenated pellets hint at incomplete hydrogen desorption and poor reversibility of compacted LNL tank, in agreement with the inferior hydrogen content released and reproduced to theoretical value during cycling (Figure 4.4). The formation of Li_2O is due to oxidation of Li-containing phases with oxygen and/or humidity during sample preparation.

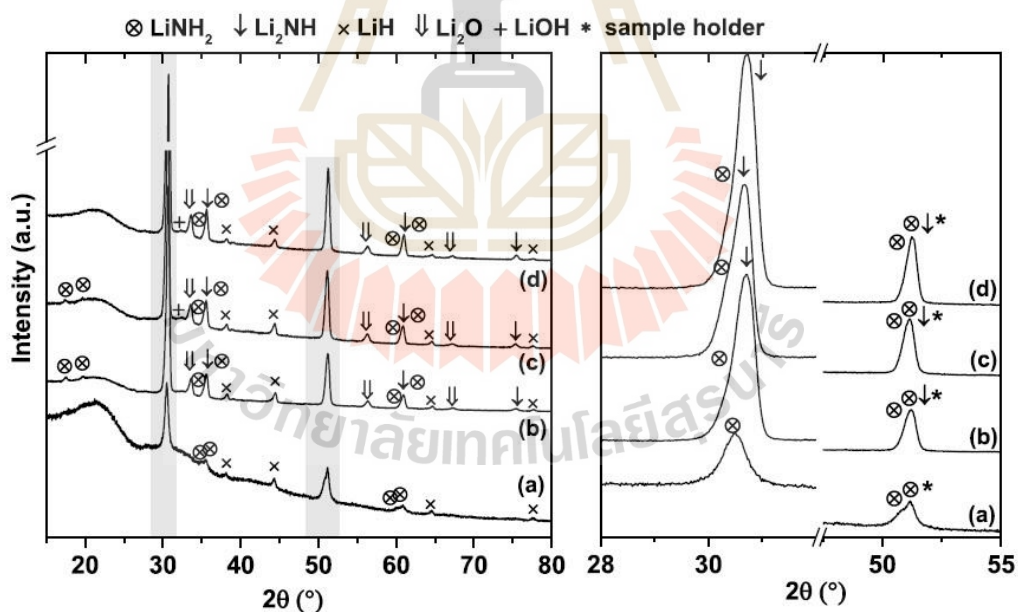

Figure 4.5 PXD spectra of as-prepared (a), dehydrogenated (b), rehydrogenated (c), and the 2nd dehydrogenated (d) samples of compacted LNL located at the middle of the tank (TC2).

In the case of compacted LNL-TiF₄-CNT, as-prepared powder sample shows the diffraction peaks of LiNH₂, LiH, and unknown phase (Figure 4.7(a)). When the reaction occurred, dehydrogenated pellet reveals characteristic peaks of Li₂NH and LiF (Figure 4.7(b)), hinting at complete dehydrogenation and reaction between TiF₄ and Li-containing phases, respectively.

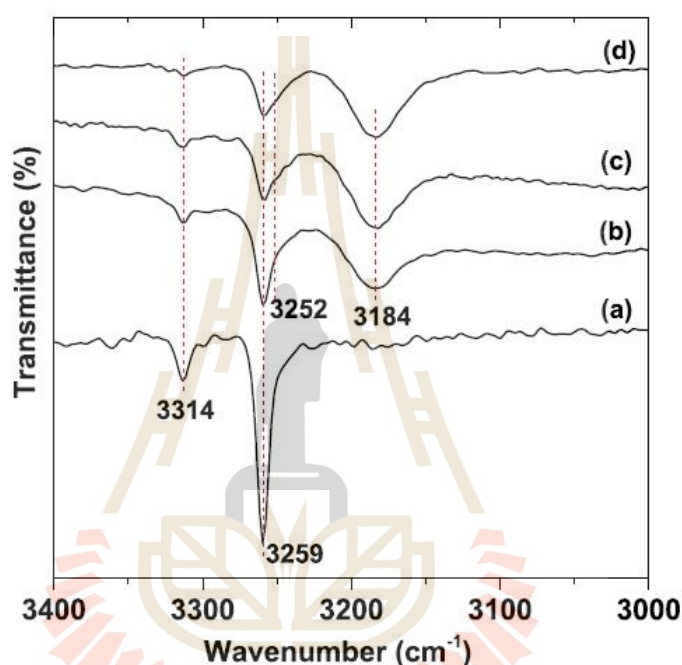

Figure 4.6 FTIR spectra of as-prepared (a), dehydrogenated (b), rehydrogenated (c), and the 2nd dehydrogenated (d) samples of compacted LNL located at the middle of the tank (TC2).

Li₂O and LiOH signals are described by the oxidation/hydrolysis of Li-containing phases during the experiments. After rehydrogenation, not only LiNH₂ and LiH are reproduced but also Li₅TiN₃ and unknown phases (Figure 4.7(c)). From the previous results, Li₅TiN₃ formed by nanocontact between LiNH₂ and Ti could absorb excess NH₃ to form Li₅TiN₃(NH₃)_x, acting as a catalyst to enhance hydrogen desorption properties of Li-N-H

system (Teng et al., 2011). This phase favored desorption kinetics and reversibility of compacted LNL-TiF₄-CNT tank as compared with compacted LNL (Figure 4.4).

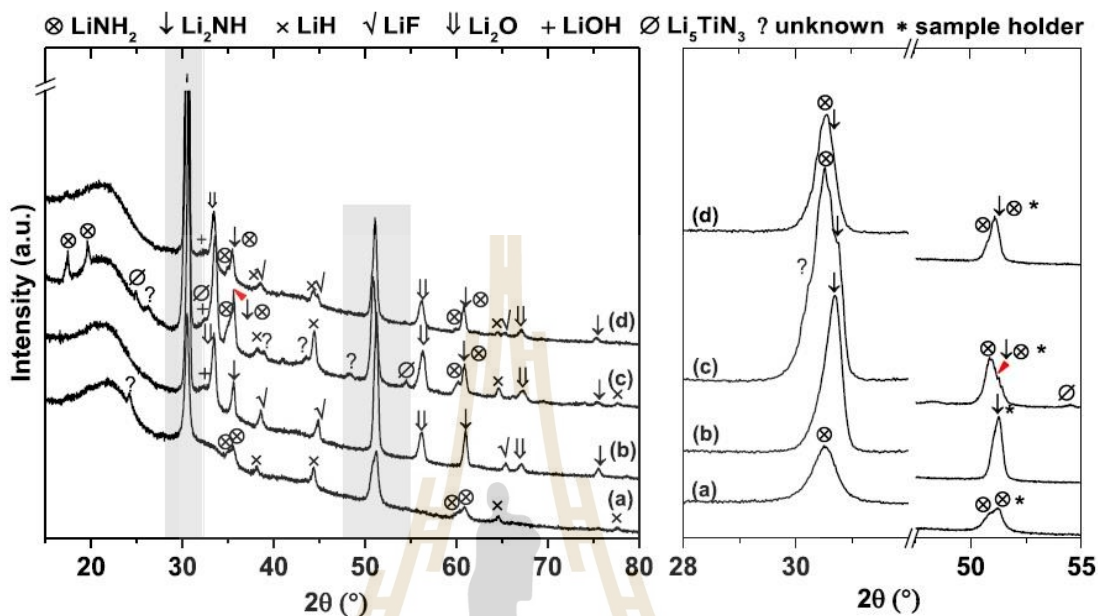

Figure 4.7 PXD spectra of as-prepared (a), dehydrogenated (b), rehydrogenated (c), and the 2nd dehydrogenated (d) samples of compacted LNL-TiF₄-CNT located at the middle of the tank (TC2).

For the 2nd desorption, diffraction patterns of LiNH₂ and LiH are recovered together with Li₂NH, LiF, Li₂O, and LiOH (Figure 4.7(d)). FTIR spectrum of as-prepared sample shows the characteristic vibrations of LiNH₂ (3314 and 3258 cm⁻¹) and Li₂NH (3252 and 3184 cm⁻¹) (Figure 4.8 (a-d)). For the dehydrogenated and rehydrogenated samples, the vibration of Li₂NH (Figure 4.8(b)) and LiNH₂ (Figure 4.8(c)) are observed, respectively. Thus, compacted LNL-TiF₄-CNT not only decomposes completely but also can be reversible. However, incomplete dehydrogenation during the 2nd cycle is confirmed by mixed vibrational peaks of LiNH₂ and Li₂NH (Figure 4.8(d)). This leads to the reduction of hydrogen capacity during the 2nd- 6th with respect to the 1st cycle of compacted LNL-TiF₄-CNT tank.

Figure 4.8 FTIR spectra of as-prepared (a), dehydrogenated (b), rehydrogenated (c), and the 2nd dehydrogenated (d) samples of compacted LNL-TiF₄-CNT located at the middle of the tank (TC2).

De/rehydrogenation performances at different positions (TC1-TC3) inside the compacted LNL-TiF₄-CNT tank are investigated. As-prepared powder showed the vibrational peaks of LiNH₂ (3314 and 3260 cm⁻¹) and Li₂NH (3250 and 3180 cm⁻¹). For dehydrogenated samples, all positions present mainly the vibration of Li₂NH with slight signal of LiNH₂ Figure 4.9. Therefore, reaction rate and mechanisms inside the compacted LNL-TiF₄-CNT tank are comparable. Moreover, the expansion/contraction of the pellet sample upon de/rehydrogenation cycles results in the deformation and/or cracks (Figure 4.10). It should be noted that both LNL and LNL-TiF₄-CNT show good mechanical stability upon cycling.

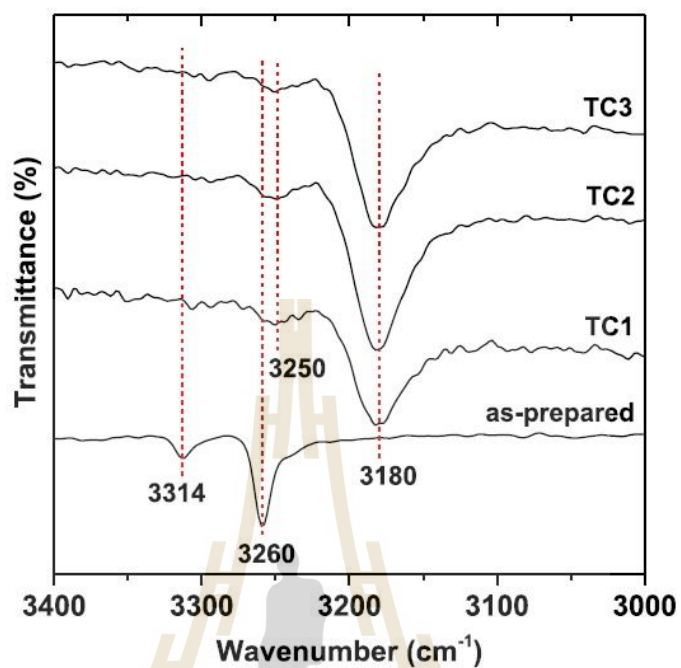

Figure 4.9 FTIR spectra of as-prepared and dehydrogenated samples at different positions inside the tank containing compacted LNL-TiF₄-CNT.

Figure 4.10 Pictures of compacted LNL and LNL-TiF₄-CNT at as-prepared state (A and C, respectively) and after cycling (B and D, respectively).

4.2 LiH-sandwiched LiNH₂-LiH-TiF₄-MWCNTs pellets

From the previous work, NH₃ emission upon cycling might still occur due to pellet deformation (Figure 4.10). In this study, we would like to propose the idea of sandwiching LiNH₂-LiH with LiH layers to prevent NH₃ emission during de/rehydrogenation cycles. To enhance hydrogen sorption kinetics and gas diffusion, TiF₄ and MWCNTs are added into the middle layer of LiNH₂-LiH, while the outer layers of LiH are doped with 1 wt. % MWCNTs. The pellets of LiH-sandwiched LiNH₂-LiH contain 10–30 wt. % of MWCNTs-doped LiH layers. Dehydrogenation kinetics, reversibility, and hydrogen exchange reactions as well as the suppression of NH₃ release upon cycling of the LiH-sandwiched LiNH₂-LiH pellets are investigated. The decompositions of as-prepared LNL and LiH-sandwiched LNL pellets are characterized by simultaneous DSC-TG-MS technique as shown in Figure 4.11. All pellet samples reveal comparable onset desorption temperatures at about 200 °C. LNL pellet shows two-step dehydrogenation at 260 and 484 °C together with NH₃ release during the second step. In the case of LiH-sandwiched LNL pellets, single-step dehydrogenation at 260–262 °C with no sign of NH₃ release are observed. For the percent weight loss, LNL pellet represents the combination of H₂ and NH₃ release (6.83 wt. %), while LiH-sandwiched LNL pellets liberate only H₂ (4.12–5.00 wt. %) (Figure 4.11). Considering comparable desorption temperatures of all LiH-sandwiched LNL pellets, the different amounts of MWCNTs-doped LiH layers (10–30 wt. %) sandwiching at both sides of LNL pellet do not affect the desorption temperature of LiNH₂-LiH composite during the first dehydrogenation. However, high content of MWCNTs-doped LiH content (30 wt. %) results in deficient hydrogen capacity of LNL-30% LiH (3.50 wt. %) with respect to other LiH-sandwiched LNL samples.

Figure 4.11 Simultaneous DSC-TG-MS results of LNL, LNL-10% LiH, LNL-20% LiH, and LNL-30% LiH pellets.

Since the dehydrogenation character of LNL-20%LiH is in between those of LNL-10% LiH and LNL-30% LiH. Further studies based on dehydrogenation kinetics, reversibility, and suppression of NH_3 release focus on the pellet samples with the lowest and the highest contents of MWCNTs-doped LiH (LNL-10% LiH and LNL-30% LiH). From Figure 4.12, total and material hydrogen capacities during the 1st cycle of LNL-10% LiH pellet are 4.97 and 3.90 wt. % H_2 , respectively, while those of LNL-30% LiH pellet are 4.27 and 3.67 wt.% H_2 , respectively. These agree with simultaneous DCS-TG-MS results at 330 °C (4.0 and 3.50 wt. % H_2 , respectively) (Figure 4.11). Both LiH-sandwiched LNL pellets are rehydrogenated under 10-15 bar, which two-step exothermic reaction are observed at all positions (TC1-TC3) (Figure 4.13).

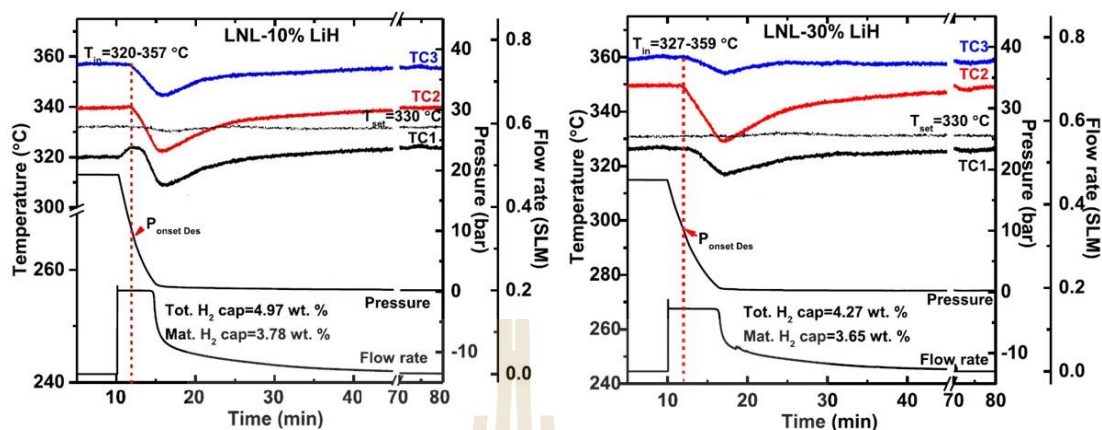

Figure 4.12 Dehydrogenation kinetics of LNL-10% LiH and LNL-30% LiH pellets.

Considering reversibility, 3.90 and 3.67 wt. % H_2 are observed during the 1st cycle of LNL-10% LiH and LNL-30% LiH, respectively (Figure 4.14). During the 2nd-6th cycles, comparable total and material capacities in the ranges of 2.9–3.3 and 2.3–2.6 wt. % H_2 , respectively, are obtained from LNL-10% LiH and LNL-30% LiH, respectively.

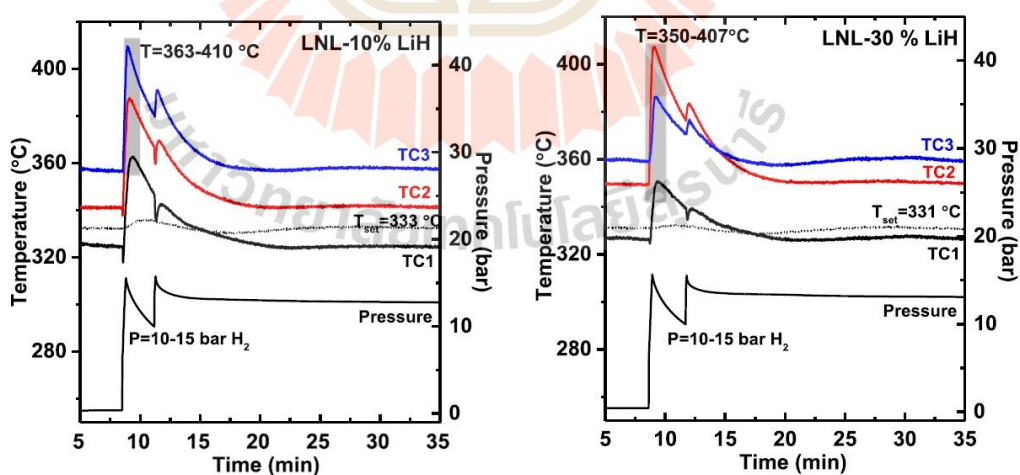

Figure 4.13 Rehydrogenation kinetics of LNL-10% LiH and LNL-30% LiH pellets.

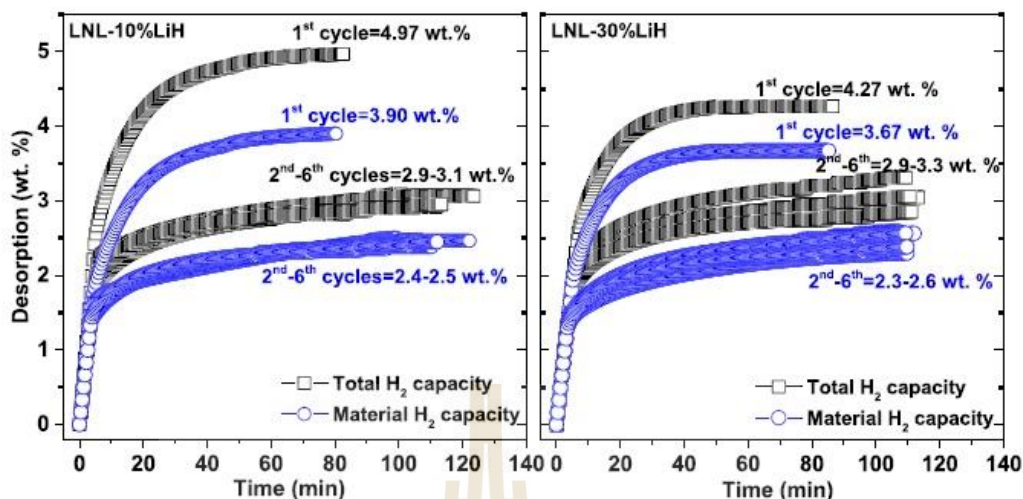

Figure 4.14 Dehydrogenation kinetics and reversibility of LNL-10% LiH and LNL-30% LiH pellets.

After cycling, the 6th rehydrogenated pellets of both LiH-sandwiched LNL samples are investigated by simultaneous DSC-TG-MS technique to confirm NH₃ suppression. Both pellet samples reveal two-step decomposition (Figure 4.15). LNL-10% LiH releases both H₂ and NH₃ at the same temperature ranges at ~250 and 400 °C, resulting in total weight loss of 8.20 wt. % (Figure 4.15(A)). While LNL-30% LiH provides only H₂-MS signal at the same temperature together with the total capacity of 4.10 wt. % H₂ (Figure 4.15(B)). LNL-10% LiH and LNL-30% LiH pellets present percent weight losses of 2.40 and 2.10 wt. %, respectively at 330 °C, approaching the contents of gases desorbed during the 2nd-6th cycles (2.3–2.6 wt. %) (Figure 4.14). Superior dehydrogenation performance upon cycling of LNL-30% LiH to LNL-10% LiH pellet can be described by the effective suppression of NH₃ release due to sufficient LiH content and mechanical stability upon cycling of LiH layer. Figure 4.16(A) shows that LNL-10% LiH pellet with the thin layers of MWCNTs-doped LiH has some defects and/or cracks on the MWCNTs-doped LiH layer after cycling, resulting in NH₃ release (Figure 4.16(A)).

Figure 4.15 Simultaneous DSC-TG-MS results of the 6th rehydrogenated pellets of LNL-10% LiH (A) and LNL-30% LiH (B).

In the case of LNL- 30% LiH, the dense pellet of LNL layer is sandwiched with the thick layers of MWCNTs-doped LiH (Figure 4.16(B)), leading to suppression of NH₃ release upon cycling. Furthermore, chemical compositions of as-prepared, dehydrogenated, and rehydrogenated states of both LiH-sandwiched LNL samples are characterized by PXD, FTIR, and XPS techniques. Due to comparable dehydrogenation kinetics during the 2nd-6th cycles, the 6th de/rehydrogenated pellets are selected to represent the hydrogen exchange reaction upon cycling. PXD pattern of as-prepared LNL-10% LiH pellet shows the diffractions pattern of LiNH₂, LiH, Li₂O, and LiTi₂O₄, while the 5th dehydrogenated sample reveals the signals of Li₂NH, LiH, Li₂O, and LiTi₂O₄ (Figure 4.17(A)(a-b)). For after the 6th rehydrogenation, the diffraction peaks of LiNH₂ and Li₅TiN₃ are observed together with other phases, similar to as-prepared and dehydrogenated samples (LiH, Li₂O, and LiTi₂O₄) (Figure 4.17(A)(c)).

Figure 4.16 Microscope images of as-prepared and the 6th rehydrogenated pellets of LNL-10% LiH (A) and LNL-30% LiH (B).

Considering the FTIR spectra, as-prepared and the 6th rehydrogenated samples show vibrational peaks of LiNH_2 at 3314 and 3260 cm^{-1} (Figure 4.17(B)(c)). For the 5th dehydrogenated sample, the vibration of Li_2NH at 3252 and 3183 cm^{-1} is observed in Figure 4.17(B)(b)). The excess of LiH from the MWCNT-doped LiH layers leads to the formation of LiTi_2O_4 . Zhang et al. (2015) proposed that LiTi_2O_4 could enhance the mobility of Li^+ ions between LiH and LiNH_2 solid phases, improving dehydrogenation of the LiNH_2 -LiH composites. Besides, Li_5TiN_3 obtained from the nanocontact between LiNH_2 and Ti (from TiF_4) could absorb the excess NH_3 to form $\text{Li}_5\text{TiN}_3(\text{NH}_3)_x$, acting as a catalyst for enhancing hydrogen desorption properties. Thus, these formations of several irreversible phases of Li_2O , LiTi_2O_4 , and Li_5TiN_3 phases affect the reduction of gas content upon cycling. For the sample of LNL-30% LiH, as-prepared pellet shows the diffractions pattern of LiNH_2 and LiH (Figure 4.18(A)(a)), while the 5th dehydrogenated pellet reveals the signals of Li_2NH^* , Li_2O , LiH, and LiF together with $\text{LiH}_{1-x}\text{F}_x$, which the diffraction is in between those of LiH and LiF (Figure 4.18(A)(b)). The formation of $\text{LiH}_{1-x}\text{F}_x$ is in accordance with the confirmed reaction between NaH and NaF to form $\text{NaH}_{1-x}\text{F}_x$, which the diffractions of $\text{NaH}_{1-x}\text{F}_x$ located between those of NaH and NaF (Humphries et al., 2016).

Figure 4.17 PXD patterns (A) and FTIR spectra (B) of the pellets at as-prepared (a), the 5th dehydrogenated (b), and the 6th rehydrogenated (c) states of LNL-10%LiH.

In the PXD result, diffraction peaks of Li₂NH* are slightly shifted to lower 2θ ($\sim 0.1^\circ$) with respect to Li₂NH (Figure 4.18(A)(b)). This indicates that the enlargement of Li₂NH unit cell is probably due to the substitution of F atoms for H in Li₂NH structure to form

$\text{Li}_2\text{NH}_{1-y}\text{F}_y$ upon cycling, identical to the formation of $\text{LiH}_{1-x}\text{F}_x$ (Figure 4.18(A)(b)). For the sample of the 6th rehydrogenation, the characteristic peaks of LiNH_2 , LiTi_2O_4 , LiH , and unknown phase are observed (Figure 4.18(A)(c)), indicating the successful reversibility of the LiNH_2 - LiH composite.

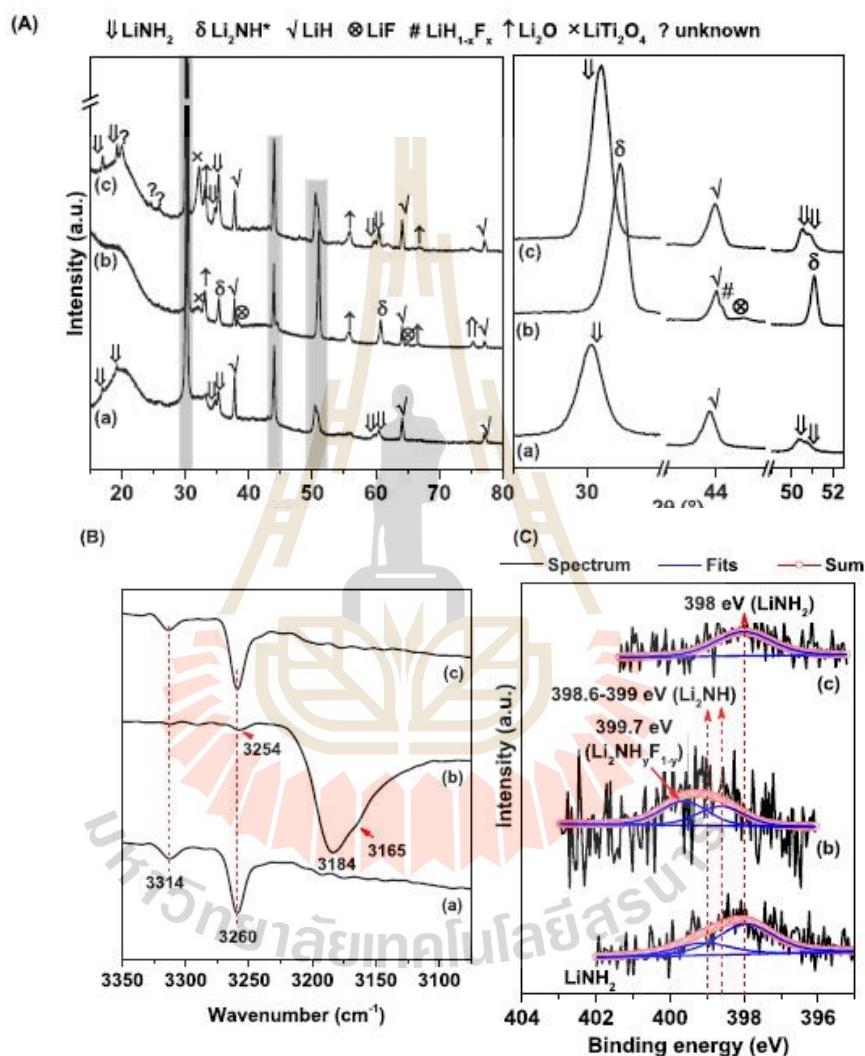

Figure 4.18 PXD patterns (A), FTIR spectra (B), and N 1s XPS spectra (C) of the pellets as prepared (a), the 5th dehydrogenated (b), and the 6th rehydrogenated (c) states of LNL-30% LiH and as-milled LiNH_2 powder samples.

FTIR spectra of as-prepared and the 6th rehydrogenated LNL-30%LiH also show comparable vibrations with those of LNL-10%LiH (Figure 4.18(B)(a) and (c)), i.e., asymmetric and symmetric N-H stretching of LiNH₂ at 3314 and 3260 cm⁻¹, respectively (Figure 4.18(B)(a) and (c)) (Kojima et al., 2005). However, the 5th dehydrogenated LNL-30% LiH shows not only characteristic peaks of Li₂NH at 3254 and 3184 cm⁻¹ but also a shoulder peak at the lower wavenumber of 3165 cm⁻¹ (Figure 4.18(B)(b)). This indicates that another N-H bond of Li₂NH with the enhanced bond length is probably attributed to the increase of electronegativity of the neighboring atom (F atom). This suggests that fluorine may substitute for hydrogen in Li₂NH to produce Li₂NH_{1-y}F_y, corresponding to PXD result. Furthermore, XPS experiments are conducted to confirm the formation of Li₂NH_{1-y}F_y. From Figure 4.18(C), N 1s XPS spectrum of as-milled LiNH₂ shows the characteristic peak of LiNH₂ and Li₂NH at 398 and 398.6 eV, respectively. The appearance of Li₂NH in as-milled LiNH₂ can be due to the partial decomposition of LiNH₂ during the milling process. For the 5th dehydrogenated pellet, signals of Li₂NH at ~399 eV together with the peak at higher binding energy at 399.7 eV are observed (Figure 4.18(C)(b)). Chemical bonding with a more electronegative atom leads to the decrease of the electron density in the valence shell of N atom, resulting in the enhanced binding energy of the N 1s orbital. Therefore, the N 1s XPS peak at higher binding energy (399.7 eV) with respect to that of N-H bond likely belonging to Li₂NH (399 eV) indicates the bonding between N and electronegative atom (i.e., N-F bond in this study). This fluorine substitution of hydride materials is possible due to the comparable ionic size of the hydride and fluoride ions as well as the structural similarity of their compounds (Humphries et al., 2016), (Messer, 1970). Thus, LNL-30%LiH provides not only sufficient LiH content to consume NH₃ but also the formation of new reactive phases of LiH_{1-x}F_x and Li₂NH_{1-y}F_y upon cycling. This leads to positive effects on de/rehydrogenation kinetics and reversibility of LiNH₂-LiH, which is confirmed by hydrogen contents reproduced upon cycling and the reaction mechanisms of F-substituted phases on kinetic properties.

CHAPTER V

CONCLUSIONS

De/rehydrogenation performances, kinetics, and reaction mechanisms of small hydrogen storage tank containing compacted $\text{LiNH}_2\text{-LiH}$ doped with TiF_4 and MWCNTs were investigated. The enhanced dehydrogenation kinetics was confirmed by the alteration of reaction pathway at lower temperature range of 150-350 °C. Moreover, hydrogen content released and reproduced at isothermal condition ($T_{\text{set}} = 335$ °C) increased from 1.90-2.40 to 3.10-4.70 wt. % H_2 . Effective dehydrogenation was confirmed by the prolonged plateau temperature range and constant hydrogen flow rate (50 sccm). Upon cycling, Li_3TiN_5 obtained from the nanocontact between LiNH_2 and Ti absorbed NH_3 to produce $\text{Li}_5\text{TiN}_3(\text{NH}_3)_x$, acting as catalyst for Li-N-H system. To further reduce NH_3 emission upon cycling, the composite of $\text{LiNH}_2\text{-LiH}$ doped with TiF_4 -MWCNTs was sandwiched with MWCNTs-doped LiH layers (10–30 wt. %). During the first dehydrogenation, compacted $\text{LiNH}_2\text{-LiH}$ released NH_3 along with H_2 , while LiH-sandwiched $\text{LiNH}_2\text{-LiH}$ pellets desorbed hydrogen without NH_3 . Kinetic properties of the 1st de/rehydrogenation of LiH- sandwiched $\text{LiNH}_2\text{-LiH}$ pellets (10 and 30 wt. % MWCNTs-doped LiH) were comparable (3.5–4.0 wt. % H_2 within 60 min). Upon the 2nd-6th cycles, the gases desorbed from the pellet samples with 10 and 30 wt. % MWCNTs-doped LiH (2.3–2.6 wt. %) were mixed H_2+NH_3 and only H_2 , respectively. Deficient reversible hydrogen contents were described by the formation of irreversible phases (Li_2O , LiTi_2O_4 , and Li_5TiN_3). The effective suppression of NH_3 obtained from the pellet with 30 wt. % MWCNTs-doped LiH was due to sufficient content and mechanical stability of LiH layers. Moreover, F substitution for H in LiH and Li_2NH to form $\text{LiH}_{1-x}\text{F}_x$ and $\text{Li}_2\text{NH}_{1-y}\text{F}_y$, respectively, were observed during dehydrogenation of the pellet with 30 wt. % MWCNTs-doped LiH. These phases likely benefited de/rehydrogenation kinetics and reversibility of the Li-N-H system.

CURRICULUM VITAE

Name Miss Chongsutthamani Sitthiwet

Date of Birth 9th August 1991

Place of Birth Nakhonrachsima, Thailand

Education (Include dates, Major and Details of Degrees, University)

2010-2013 B.Sc. (Chemistry), Rajamankala University of Technology
Isan, Thailand

2014-2022 Ph.D. (Chemistry), Suranaree University of Technology,
Thailand
